We shall then consider the principle of uniform motion, the equilibrium between the power and the resistance. The power is the relative height of the column of fluid which tends to move along the inclined plane of its bed; the resistance is the friction of the bed, the viscidity of the fluid, and its adhesion to the sides. Here is necessarily combined a number of circumstances which must be gradually detached, that we may see the effect of each, viz. the extent of the bed, its perimeter, and its slope. By examining the effects produced by variations of each of these separately, we discover what share each has in the general effect; and having thus analysed the complicated phenomena, we shall be able to combine those its elements, and frame a formula which shall comprehend every circumstance, from the greatest velocity to the extinction of all motion, and from the extent of a river to the narrow dimensions of a quill. We shall compare this formula with a series of experiments in all this variety of circumstances, partly made by Mr Buat, and partly collected from other authors; and we shall leave the reader to judge of the agreement.

Confident that this agreement will be found most satisfactory, we shall then proceed to consider very cursorily the chief varieties which nature or art may introduce into these beds, the different velocities of the same stream, the intensity of the resistance produced by the inertia of the materials of the channel, and the force of the current by which it continually acts on this channel, tending to change either its dimensions or its form. We shall endeavour to trace the origin of these great rivers which spread like the branches of a vigorous tree, and occupy the surface even of a vast continent. We shall follow them in their course, unfold all their windings, study their train and regimen, and point out the law of its stability; and we shall investigate the causes of their deviations and wanderings.

The study of these natural laws pleases the mind: but it answers a still greater purpose; it enables us to assist nature, and to hasten her operations, which our wants and our impatience often find too slow. It enables us to command the elements, and to force them to administer to our wants and our pleasures.

We shall therefore, in the next place, apply the knowledge which we may acquire to the solution of the most important hydraulic questions which occur in the practice of the civil engineer.

We shall consider the effects produced by a permanent addition to any river or stream by the union of another, and the opposite effect produced by any draught or offset, showing the elevation or depression produced up the stream, and the change made in the depth and velocity below the addition or offset.

We shall pay a similar attention to the temporary swells produced by freshes.

We shall ascertain the effects of straightening the course of a stream, which, by increasing its slope, must increase its velocity, and therefore sink the waters above the place where the curvature was removed, and diminish the tendency to overflow, while the same immediate consequence must expose the places farther down to the risk of floods, from which they would otherwise have been free.

The effects of dams or weirs, and of bars, must then be considered; the gorge or swell which they produce up the stream must be determined for every distance from the weir or bar. This will furnish us with rules for rendering navigable or floatable such waters as have too little depth or too great slope. And it will appear that immense advantages may be thus derived, with a moderate expense, even from trifling brooks, if we will relinquish all prejudices, and not imagine that such conveyance is impossible because it cannot be carried on by such boats and small craft as we have been accustomed to look at.

The effects of canals of derivation, the rules or maxims of draining, and the general maxims of embankment, come in the next place; and our discussions will conclude with remarks on the most proper forms for the entry to canals, locks, docks, harbours, and mouths of rivers, the best shape for the startlings of bridges and of boats for inland navigation, and such like subordinate but interesting particulars, which will be suggested by the general thread of discussion.

Natural velocity, expense, and discharge, through small orifices.

It is considered as physically demonstrated (see HYDRODYNAMICS), that water issuing from a small orifice in the bottom or side of a very large vessel, almost instantly acquires and maintains the velocity which a heavy body would acquire by falling to the orifice from the horizontal surface of the stagnant water. This we shall call its NATURAL VELOCITY. Therefore, if we multiply the area of the orifice by this velocity, the product will be the bulk or quantity of the water which is discharged. This we may call the NATURAL EXPENSE of water, or the NATURAL DISCHARGE.

Let O represent the area or section of the orifice expressed in some known measure, and h its depth under the surface. Let g express the velocity acquired by a heavy body during a second by falling. Let V be the medium velocity of the water's motion, Q the quantity of water discharged during a second, and N the natural expense.

We know that V is equal to $\sqrt{2g} \times \sqrt{h}$. Therefore $N = O \sqrt{2g} \sqrt{h}$.

If these dimensions be all taken in English feet, we have $\sqrt{2g}$ very nearly equal to 8; and therefore $V = 8 \sqrt{h}$, and $N = O\, 8 \sqrt{h}$.

But in our present business it is much more convenient to measure every thing by inches. Therefore, since a body acquires the velocity of 32 feet 2 inches in a second, we have $2g = 64$ feet 4 inches, or 772 inches, and $\sqrt{2g} = 27{\cdot}78$ inches, nearly $27\frac{3}{4}$ inches.

Therefore $V = \sqrt{772} \sqrt{h}, = 27{\cdot}78 \sqrt{h}$, and $N = O \sqrt{772} \sqrt{h}, = O\, 27{\cdot}78 \sqrt{h}$.

But it is also well known, that if we were to calculate the expense or discharge for every orifice by this simple rule, we should in every instance find it much greater than nature really gives us.

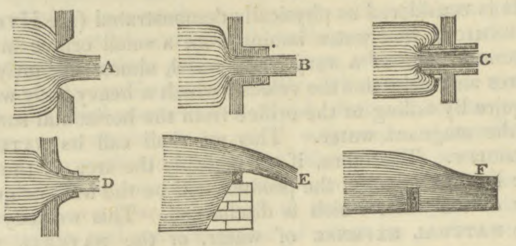
Contraction.

When water issues through a hole in a thin plate, the lateral columns, pressing into the hole from all sides, cause the issuing filaments to converge to the axis of the jet, and contract its dimensions at a little distance from the hole. And it is in this place of greatest contraction that the water acquires that velocity which we observe in our experiments, and which we assume as equal to that acquired by falling from the surface. Therefore, that our computed discharge may best agree with observation, it must be calculated on the supposition that the orifice is diminished to the size of this smallest section. But the contraction is subject to variations, and the dimensions of this smallest section are at all times difficult to ascertain with precision. It is therefore much more convenient to compute from the real dimensions of the orifice, and to correct this computed discharge, by means of an actual comparison of the computed and effective discharges in a series of experiments made in situations resembling those cases which most frequently occur in practice. This correction, or its cause, in the mechanism of those internal motions, is generally called CONTRACTION by the writers on hydraulics; and it is not confined to a hole in a thin plate: it happens in some degree in all cases where fluids are made to pass through narrow places. It happens in the entry into all pipes, canals, and sluices; nay even into the passage of water over the edge of a board, such as is usually set up on the head of a

Theory.

dam or weir, and even when this is immersed in water on both sides, as in a bar or keep, frequently employed for raising the waters of the level streams in Flanders in order to render them navigable. We mentioned an observation[1] of Mr Buat to this effect, when he saw a gooseberry rise up from the bottom of the canal along the face of the bar, and then rapidly fly over its top. We have attempted to represent this motion of the filaments in these different situations.

Fig. 5.



Motion of filaments in various particular situations,

A shows the motion through a thin plate.

B shows the motion when a tube of about two diameters long is added, and when the water flows with a full mouth. This does not always happen in so short a pipe (and never in one that is shorter), but the water frequently detaches itself from the sides of the pipe, and flows with a contracted jet.

C shows the motion when the pipe projects into the inside of the vessel. In this case it is difficult to make it flow full.

D represents a mouth-piece fitted to the hole, and formed agreeably to that shape which a jet would assume of itself. In this case all contraction is avoided, because the mouth of this pipe may be considered as the real orifice, and nothing now diminishes the discharge but a trifling friction of the sides.

E shows the motion of water over a dam or weir, where the fall is free or unobstructed; the surface of the lower stream being lower than the edge or sole of the waste-board.

F is a similar representation of the motion of water over what we would call a *bar* or *keep*.

and the effects of contraction determined.

It was one great aim of the experiments of Michelotti and Bossut to determine the effects of contraction in these cases. Michelotti, after carefully observing the form and dimensions of the natural jet, made various mouth-pieces resembling it, till he obtained one which produced the smallest diminution of the computed discharge, or till the discharge computed for the area of its smaller end approached the nearest to the effective discharge. And he at last obtained one which gave a discharge of 983, when the natural discharge would have been 1000. This piece was formed by the revolution of a trochoid round the axis of the jet, and the dimensions were as follow:

Diameter of the outer orifice = 36
Diameter of the inner orifice = 46
Length of the axis = 96

The results of the experiments of the Abbé Bossut and of Michelotti scarcely differ, and they are expressed in the following table:

N or the natural expense	$10000 = 0{\cdot}27{\cdot}78\sqrt{h}$
Q for the thin plate, fig. A, almost at the surface	$6526 = 0{\cdot}18{\cdot}13\sqrt{h}$
Q for ditto at the depth of 8 feet	$6195 = 0{\cdot}17{\cdot}21\sqrt{h}$
Q for ditto at the depth of 16 feet	$6173 = 0{\cdot}17{\cdot}15\sqrt{h}$
Q for a tube 2 diameters long, fig. B	$8125 = 0{\cdot}22{\cdot}57\sqrt{h}$
Q for ditto projecting inwards and flowing full	$6814 = 0{\cdot}18{\cdot}93\sqrt{h}$
Q for ditto with a contracted jet, fig. C	$5137 = 0{\cdot}14{\cdot}27\sqrt{h}$
Q for the mouth-piece, fig. D	$9831 = 0{\cdot}27{\cdot}31\sqrt{h}$
Q for a weir, fig. E	$9536 = 0{\cdot}26{\cdot}49\sqrt{h}$
Q for a bar, fig. F	$9730 = 0{\cdot}27{\cdot}03\sqrt{h}$

Theor

The numbers in the last column of this little table are the cubical inches of water discharged in a second when the height *h* is one inch.

It must be observed, that the discharges assigned here for the weir and bar relate only to the contractions occasioned by the passage over the edge of the board. The weir may also suffer a diminution by the contractions at its two ends, if it should be narrower than the stream, which is generally the case, because the two ends are commonly of square masonry or wood-work. The contraction there is nearly the same with that at the edge of a thin plate. But this could not be introduced into this table, because its effect on the expense is the same in quantity whatever is the length of the waste-board of the weir.

Diminution of d charge through sluice, &

In like manner, the diminution of discharge through a sluice could not be expressed here. When a sluice is drawn up, but its lower edge still remains under water, the discharge is contracted both above and at the sides, and the diminution of discharge by each is in proportion to its extent. It is not easy to reduce either of these contractions to computation, but they may be very easily observed. We frequently can observe the water, at coming out of a sluice into a mill-course, quit the edge of the aperture, and show a part of the bottom quite dry. This is always the case when the velocity of efflux is considerable. When it is very moderate, this place is occupied by an eddy water almost stagnant. When the head of water is eight or ten inches, and runs off freely, the space left between it and the sides is about one and a half inch. If the sides of the entry have a slope, this void space can never appear; but there is always this tendency to convergence, which diminishes the quantity of the discharge.

It will frequently abridge computation very much to consider the water discharged in these different situations as moving with a common velocity, which we conceive as produced not by a fall from the surface of the fluid (which is exact only when the expense is equal to the natural expense), but by a fall *h* accommodated to the discharge: or it is convenient to know the height which would produce that very velocity which the water issues with in these situations.

And also, when the water is observed to be actually moving with a velocity V, and we know whether it is coming through a thin plate, through a tube, over a dam, &c. it is necessary to know the pressure or HEAD OF WATER *h* which has actually produced this velocity. It is convenient therefore to have the following numbers in readiness.

h for the natural expense	$= \frac{V^2}{772}$
h for a thin plate at the depth of 8 feet	$= \frac{V^2}{296}$
h for a tube 2 diam. long	$= \frac{V^2}{509}$
h for a dam or weir	$= \frac{V^2}{702}$
h for a bar	$= \frac{V^2}{731}$

It was necessary to premise these facts in hydraulics,

---

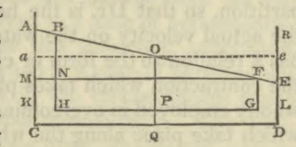
T ory.

that we may be able in every case to distinguish between the force expended in the entry of the water into the conduit or canal, and the force employed in overcoming the resistances along the canal, and in preserving or accelerating its motion in it.

Th no- tion f ri- ver le- pen on the ope of t sur- face

Fig. 6.



The motion of running water is produced by two causes: 1. The action of gravity; and, 2. the mobility of the particles, which makes them assume a level in confined vessels, or determines them to move to that side where there is a defect of pressure. When the surface is level, every particle is at rest, being equally pressed in all directions; but if the surface is not level, not only does a particle on the very surface tend by its own weight towards the lower side, as a body would slide along an inclined plane, but there is a force, external to itself, arising from a superiority of pressure on the upper end of the surface, which pushes this superficial particle towards the lower end; and this is not peculiar to the superficial particles, but affects every particle within the mass of water. In the vessel ACDE (fig. 6), containing water with an inclined surface AE, if we suppose all frozen but the extreme columns AKHB, FGLE, and a connecting portion HKCDLG, it is evident, from hydrostatical laws, that the water on this connecting part will be pushed in the direction CD; and if the frozen mass BHGF were moveable, it would also be pushed along. Giving it fluidity will make no change in this respect; and it is indifferent what is the situation and shape of the connecting column or columns. The propelling force (MNF being horizontal) is the weight of the column AMNB. The same thing will obtain wherever we select the vertical columns. There will always be a force tending to push every particle of water in the direction of the declivity. The consequence will be, that the water will sink at one end and rise at the other, and its surface will rest in the horizontal position *a* O *e*, cutting the former in its middle O. This cannot be, unless there be not only a motion of perpendicular descent and ascent of the vertical columns, but also a real motion of translation from K towards L. It perhaps exceeds our mathematical skill to tell what will be the motion of each particle. Newton did not attempt it in his investigation of the motion of waves, nor is it at all necessary here. We may, however, acquire a very distinct notion of its general effect. Let OPQ be a vertical plane passing through the middle point O. It is evident that every particle in PQ, such as P, is pressed in the direction QD, with a force equal to the weight of a single row of particles whose length is the difference between the columns BH and FG. The force acting on the particle Q is, in like manner, the weight of a row of particles = AC — ED. Now if OQ, OA, OE, be divided in the same ratio, so that all the figures ACDE, BHGF, &c. may be similar, we see that the force arising solely from the declivity, and acting on each particle on the plane OQ, is proportional to its depth under the surface, and that the row of particles ACQDE, BHPGF, &c. which is to be moved by it, is in the same proportion. Hence it unquestionably follows, that the accelerating force on each particle of the row is the same in all. Therefore the whole plane OQ tends to advance forward together with the same velocity; and in the instant immediately succeeding, all these particles would be found again in a vertical plane indefinitely nearer to OQ; and if we sum up the forces, we shall find them the same as if OQ were the opening of a sluice, having the water on the side of D standing level with O, and the water on the other side standing at the height AC. This result is extremely different from that of the hasty theory of Guglielmini. He considers each particle in OQ as urged by an accelerating force proportional to its depth, it is true; but he makes it *equal* to the weight of the row OP, and never recollects that the greatest part of it is balanced by an opposite pressure, nor perceives that the force which is not balanced must be distributed among a row of particles which varies in the same proportion with itself. When these two circumstances are neglected, the result will be incompatible with observation. When the balanced forces are taken into the account of pressure, it is evident that the surface may be supposed horizontal, and that motion should obtain in this case as well as in the case of a sloping surface; and indeed this is Guglielmini's professed theory, and what he highly values himself upon. He announces this discovery of a new principle, which he calls the energy of deep waters, as an important addition to hydraulics. It is owing to this, says he, that the great rivers are not stagnant at their mouths, where they have no perceptible declivity of surface, but, on the contrary, have greater energy and velocity than farther up, where they are shallower. This principle is the basis of his improved theory of rivers, and is insisted on at great length by all the subsequent writers. Buffon, in his theory of the earth, makes much use of it. We cannot but wonder that it has been allowed a place in the theory of rivers given in the great *Encyclopédie* of Paris, and in an article having the signature (O) of D'Alembert. We have been very anxious to show the falsity of this principle, because we consider it as a mere subterfuge of Guglielmini, by which he was able to patch up the mathematical theory which he had so hastily taken from Newton or Galileo; and we think that we have secured our readers from being misled by it, when we show that this energy must be equally operative when the surface is on a dead level. The absurdity of this is evident. We shall see by and by, that deep waters, when in actual motion, have an energy not to be found in shallow running waters, by which they are enabled to continue that motion; but this is not a moving principle; and it will be fully explained, as an immediate result of principles, not vaguely conceived and indistinctly expressed, like this of Guglielmini, but easily understood, and appreciable with the greatest precision. It is an energy common to all great bodies. Although they lose as much momentum in surmounting any obstacle as small ones, they lose but a small portion of their velocity. At present, employed only in considering the progressive motion of an open stream, whose surface is not level, it is quite enough that we see that such a motion must obtain, and that we see that there are propelling forces; that those forces arise *solely* from the want of a level surface, or from the slope of the surface; and that, with respect to any one particle, the force acting on it is proportional to the difference of level between each of the two columns (one on each side of the particle) which produce it. Were the surface level, there would be no motion; if it is not level, there will be motion; and this motion will be proportional to the want of level or the declivity of the surface: it is of no consequence whether the bottom be level or not, or what is its shape.

Theory.

Hence we draw a fundamental principle, that the *motion of rivers depends entirely on the slope of the surface.*

The SLOPE or declivity of any inclined plane is not properly expressed by the difference of height alone of its extremities; we must also consider its length; and the measure of the slope must be such that it may be the same while the declivity is the same. It must therefore be the same over the whole of any one inclined plane. We shall answer these conditions exactly, if we take for the measure of a slope the fraction which expresses the elevation of one extremity above the other divided by the length of the plane. Thus $\frac{AM}{AF}$ will express the declivity of the plane AF.

Theory.

When it is uniform the resistance is equal to the accelerating force.

If the water met with no resistance from the bed in which it runs, if it had no adhesion to its sides and bottom, and if its fluidity were perfect, its gravity would accelerate its course continually, and the earth and its inhabitants would be deprived of all the advantages which they derive from its numberless streams. They would run off so quickly, that our fields, dried up as soon as watered, would be barren and useless. No soil could resist the impetuosity of the torrents; and their accelerating force would render them a destroying scourge, were it not that, by kind Providence, the resistance of the bed, and the viscidity of the fluid, become a check which reins them in and sets bounds to their rapidity. In this manner the friction on the sides, which, by the viscidity of the water, is communicated to the whole mass, and the very adhesion of the particles to each other, and to the sides of the channel, are the causes which make the resistances bear a relation to the velocity; so that the resistances, augmenting with the velocities, come at last to balance the accelerating force. Then the velocity now acquired is preserved, and the motion becomes uniform, without being able to acquire new increase, unless some change succeeds either in the slope or in the capacity of the channel. Hence arises the second maxim in the motion of rivers, that *when a stream moves uniformly, the resistance is equal to the accelerating force.*

As in the efflux of water through orifices, we pass over the very beginnings of the accelerated motion, which is a matter of speculative curiosity, and consider the motion in a state of permanency, depending on the head of water, the area of the orifice, the velocity, and the expense; so in the theory of the uniform motion of rivers, we consider the slope, the transverse section or area of the stream, the uniform velocity, and the expense. It will be convenient to affix precise meanings to the terms which we shall employ.

Terms precisely explained.

The SECTION of a stream is the area of a plane perpendicular to the direction of the general motion.

The resistances arise ultimately from the action of the water on the internal surface of the channel, and must be proportional (*cæteris paribus*) to the extent of the action. Therefore, if we unfold the whole edge of this section, which is rubbed as it were by the passing water, we shall have a measure of the extent of this action. In a pipe, circular or prismatical, the whole circumference is acted on; but in a river or canal ACDR (fig. 6) the horizontal line *a*O*e*, which makes the upper boundary of the section *a*CD*e*, is free from all action. The action is confined to the three lines *a*C, CD, D*e*. We shall call this line *a*CD*e* the BORDER of the section.

The MEAN VELOCITY is that with which the whole section, moving equally, would generate a solid equal to the expense of the stream. This velocity is to be found perhaps but in one filament of the stream, and we do not know in which filament it is to be found.

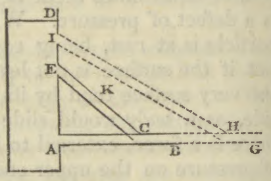
Since we are attempting to establish an empirical theory of the motion of rivers, founded entirely on experiments, and palpable deductions from them, and since it is extremely difficult to make experiments on open streams which shall have a precision sufficient for such an important purpose, it would be a most desirable thing to demonstrate an exact analogy between the mutual balancing of the acceleration and resistance in pipes and in rivers; for in those we can not only make experiments with all the desired accuracy, and admitting precise measures, but we can make them in a number of cases that are almost impracticable in rivers. We can increase the slope of a pipe from nothing to the vertical position, and we can employ every desired degree of pressure, so as to ascertain its effect on the velocity in degrees which open streams will not admit of. The Chevalier de Buat has most happily succeeded in this demonstration; and it is here that his good fortune and his penetration have done so much service to practical science.

Theo

The acc leratio and re ance of ter in a horizon tube,

Let AB (fig. 7) be a horizontal tube, through which the water is impelled by the pressure or HEAD DA. This head is the moving power; and it may be conceived as consisting of two parts, performing two distinct offices. One of them is employed in impressing on the water that velocity with which it *actually moves* in the tube. Were there no obstructions to this motion, no greater head would be wanted; but there are obstructions, arising from friction, adhesion, and viscidity. This requires force. Let this be the office of the rest of the head of water in the reservoir. There is but one allotment, appropriation, or repartition of the whole head which will answer. Suppose E to be the point of partition, so that DE is the head necessary for impressing the actual velocity on the water (a head or pressure which has a relation to the form or circumstance of the entry, and the contraction which takes place there). The rest EA is wholly employed in overcoming the simultaneous resistances which take place along the whole tube AB, and is in equilibrio with this resistance. Therefore, if we apply at E a tube EC, of the same length and diameter with AB, and having the same degree of polish or roughness; and if this tube be inclined in such a manner that the axis of its extremity may coincide with the axis of AB in the point C; we affirm that the velocity will be the same in both pipes, and that they will have the same expense; for the moving force in the sloping pipe EC is composed of the whole weight of the column DE and the relative weight of the column EC; but this relative weight, by which alone it descends along the inclined pipe EC, is precisely equal to the weight of a vertical column EA of the same diameter. Everything therefore is equal in the two pipes, viz. the lengths, the diameters, the moving forces, and the resistances; therefore the velocities and discharges will also be equal.

Fig. 7.



This is not only the case on the whole, but also in every part of it. The relative weight of any part of it EK is precisely in equilibrio with the resistances along that part of the pipe; for it has the same proportion to the whole relative weight that the resistance has to the whole resistance. Therefore (*and this is the most important circumstance, and the basis of the whole theory*) the pipe EC may be cut shorter, or may be lengthened to infinity, without making any change in the velocity or expense, so long as the propelling head DE remains the same.

Leaving the whole head DA as it is, if we lengthen the horizontal pipe AB to G, it is evident that we increase the resistance without any addition of force to overcome it. The velocity must therefore be diminished; and it will now be a velocity which is produced by a smaller head than DE: therefore, if we were to put in a pipe of equal length at E, terminating in the horizontal line AG, the water will not run equally in both pipes. In order that it may, we must discover the diminished velocity with which the water now actually runs along AG, and we must make a head DI capable of impressing this velocity at the entry of the pipe, and then insert at I a pipe IH of the same length with AG. The expense and velocity of both pipes will now be the same.[1]

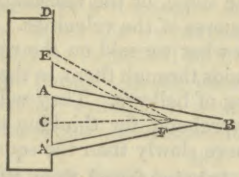
---

[1] We recommend it to the reader to make this distribution or allotment of the different portions of the pressure very familiar to his mind. It is of the most extensive influence in every question of hydraulics, and will on every occasion give him distinct conceptions of the internal procedure. Obvious as the thought seems to be, it has escaped the attention of all the writers on the subject.

or i n in- clin pipe.

What has now been said of a horizontal pipe AB would have been equally true of any inclined pipe AB A′B (fig. 8). Drawing the horizontal line CB, we see that DC is the whole head or propelling pressure for either pipe AB or A′B; and if DE is the head necessary for the actual velocity, EC is the head necessary for balancing the resistances; and the pipe EF, of the same length with AB, and terminating in the same horizontal line, will have the same velocity: and its inclination being thus determined, it will have the same velocity and expense whatever be its length.

Fig. 8.



Ana gy betv n thes pipes and vers dem stra- ted De Bua

Thus we see that the motion in any pipe, horizontal or sloping, may be referred to or substituted for the motion in another inclined pipe, whose head of water, above the place of entry, is that productive of the actual velocity of the water in the pipe. Now, in this case, the accelerating force is equal to the resistance: we may therefore consider this last pipe as a river, of which the bed and the slope are uniform or constant, and the current in a state of permanency; and we now may clearly draw this important conclusion, that pipes and open streams, when in a state of permanency, perfectly resemble each other in the circumstances which are the immediate causes of this permanency. The equilibrium between the accelerating force obtains not only in general, but takes place through the whole length of the pipe or stream, and is predicable of every individual transverse section of either. To make this more palpably evident, if possible, let us consider a sloping cylindrical pipe, the current of which is in a state of permanency. We can conceive it as consisting of two half cylinders, an upper and a lower. These are running together at an equal pace; and the filaments of each immediately contiguous to the separating plane and to each other are not rubbing on each other, nor affecting each other's motions in the smallest degree. It is true that the upper half is pressing on the lower, but in a direction perpendicular to the motion, and therefore not affecting the velocity; and we shall see presently, that although the lower side of the pipe bears somewhat more pressure than the other, the resistances are not changed. Indeed this odds of pressure is accompanied with a difference of motion, which need not be considered at present; and we may suppose the pipe so small or so far below the surface that this shall be insensible. Now let us suppose, that in an instant the upper half cylinder is annihilated: we then have an open stream; and every circumstance of accelerating force and of resistance remains precisely as it was. The motion must therefore continue as it did; and in this state the only accelerating force is the slope of the surface. The demonstration therefore is complete.

Conse quenc

From these observations and reasonings we draw a general and important conclusion, "that the same pipe will be susceptible of different velocities, which it will preserve uniform to any distance, according as it has different inclinations; and each inclination of a pipe of given diameter has a certain velocity peculiar to itself, which will be maintained uniform to any distance whatever; and this velocity increases continually, according to some law, to be discovered by theory or experiment, as the position of the pipe changes from being horizontal till it becomes vertical; in which position it has the greatest uniform velocity possible relative to its inclination, or depending on inclination alone."

Let this velocity be called the TRAIN, or the RATE, of each pipe.

Measure of the resistance to the motion with a given velocity.

It is evident that this principle is of the utmost consequence in the theory of hydraulics; for by experiment we can find the train of any pipe. It is in train when an increase of length makes no change in the velocity. If lengthening the pipe increases the velocity, the slope of the pipe is too great, and *vice versa*. And having discovered the train of a pipe, and observed its velocity, and computed the head productive of this velocity with the contraction at the entry, the remainder of the head, that is, the slope (for this is equivalent to EA), is the measure of the resistance. Thus we obtain the measure of the resistance to the motion with a given velocity in a pipe of given diameter. If we change only the velocity, we get the measure of the new resistance relative to the velocity; and thus discover the law of relation between the resistance and velocity. Then, changing only the diameter of the pipe, we get the measure of the resistance relative to the diameter. This is the aim of a prodigious number of experiments made and collected by De Buat, and which we shall not repeat, but only give the results of the different parts of his investigation.

Results of De Buat's investigation on this subject.

We may express the slope of a pipe by the symbol $\frac{1}{s}$, 1 being an inch, for instance, and s being the slant length of a pipe which is one inch more elevated at one end than at the other. Thus a river which has a declivity of an inch and a half in 120 fathoms or 8640 inches, has its slope $= \frac{1\frac{1}{2}}{8640}$, or $\frac{1}{5760}$. But in order to obtain the hydraulic slope of a conduit-pipe, the height of the reservoir and place of discharge being given, we must subtract from the difference of elevation the height or head of water necessary for propelling the water into any pipe with the velocity V, which it is supposed actually to have. This is $\frac{V^2}{509}$. The remainder d is to be considered as the height of the declivity, which is to be distributed equally over the whole length l of the pipe, and the slope is then $\frac{d}{l} = \frac{1}{s}$.

There is another important view to be taken of the slope, which the reader should make very familiar to his thoughts. It expresses the proportion between the weight of the whole column which is in motion and the weight which is employed in overcoming the resistance; and the resistance to the motion of any column of water is equal to the weight of that column multiplied by the fraction $\frac{1}{s}$, which expresses its slope.

Of the resistances which bring the motions to a state of uniformity.

We now come to consider more particularly the resistances which in this manner bring the motion to a state of uniformity. If we consider the resistances which arise from a cause analogous to friction, we see that they must depend entirely on the inertia of the water. What we call the resistance is the diminution of a motion which *would* have obtained but for these resistances; and the best way we have of measuring them is by the force which we must employ in order to keep up or restore this motion. We estimate this motion by a progressive velocity, which we mea-

---

Lecchi, in his Hydraulics, published in 1766, ascribes something like it to Daniel Bernoulli; but Bernoulli, in the passage quoted, only speaks of the partition of pressure in the instant of opening an orifice. Part of it, says he, is employed in accelerating the quiescent water, and producing the velocity of efflux, and the remainder produces the pressure (now diminished) on the sides of the vessel. Bernoulli, Bossut, and all the good writers, make this distribution in express terms in their explanation of the motion of water through successive orifices; and it is surprising that no one before the Chevalier de Buat saw that the resistance arising from friction required a similar partition of the pressure; but though we should call this good fortune, we must ascribe to his great sagacity and justness of conception the beautiful use that he has made of it: *suum cuique.*

Theory.

sure by the expense of water in a given time. We judge the velocity to diminish when the quantity discharged diminishes; yet it may be otherwise, and probably is otherwise. The absolute velocity of many, if not all, of the particles, may even be increased; but many of the motions being transverse to the general direction, the quantity of motion in this direction may be less, while the sum of the absolute motions of all the particles may be greater. When we increase the general velocity, it is not unreasonable to suppose that the impulses on all the inequalities are increased in this proportion; and the number of particles thus impelling and deflected at the same time will increase in the same proportion. The whole quantity, therefore, of these useless and lost motions will increase in the duplicate ratio of the velocities, and the force necessary for keeping up the motion will do so also; that is, the resistances should increase as the squares of the velocities.

Or if we consider the resistances as arising merely from the curvature of the imperceptible internal motions occasioned by the inequalities of the sides of the pipe, and as measured by the forces necessary for producing these curvilineal motions; then, because the curves will be the same whatever are the velocities, the deflecting forces will be as the squares of the velocities; but these deflecting forces are pressures, propagated from the parts urged or pressed by the external force, and are proportional to these external pressures by the principles of hydrostatics. Therefore the pressures or forces necessary for keeping up the velocities are as the squares of these velocities; and they are our only measures of the resistances which must be considered as following the same ratio. Whatever view therefore we take of the nature of these resistances, we are led to consider them as proportional to the squares of the velocities.

We may therefore express the resistances by the symbol $\frac{V^2}{m}$, m being some number to be discovered by experiment. Thus, in a particular pipe, the diminution of the motion or the resistance may be the 1000th part of the square of the velocity, and $R = \frac{V^2}{1000}$.

Now if g be the accelerating power of gravity on any particle, $\frac{g}{s}$ will be its accelerating power by which it would urge it down the pipe whose slope is $\frac{1}{s}$. Therefore, by the principle of uniform motion, the equality of the accelerating force, and the resistance, we shall have $\frac{V^2}{m} = \frac{g}{s}$, and $V\sqrt{s} = \sqrt{mg}$; that is, the product of the velocity, and the reciprocal of the square root of the slope, or the quotient of the velocity divided by the square root of the slope, is a constant quantity $\sqrt{mg}$ for any given pipe; and the primary formula for all the uniform velocities of one pipe is $V = \frac{\sqrt{mg}}{\sqrt{s}}$.

Experiments and reasoning of DeBuat, respecting these resistances, &c.

Mr Buat therefore examined this by experiment, but found, that even with respect to a pipe or channel which was uniform throughout, this was not true. We could give at once the final formula which he found to express the velocity in every case whatever; but this would be too empirical. The chief steps of his very sagacious investigation are instructive. We shall therefore mention them briefly, at least as far as they tend to give us any collateral information; and let it always be noted, that the instruction which they convey is not abstract speculation, but experimental truths, which must ever remain as an addition to our stock of knowledge, although Mr Buat's deductions from them should prove false.

He found, in the first place, that in the same channel the product of V and $\sqrt{s}$ increased as $\sqrt{s}$ increased; that is, the velocities increased faster than the square roots of the slope, or the resistances did not increase as fast as the squares of the velocities. We beg leave to refer our readers to what we said on the resistance of pipes to the motion of fluids through them, in the article PNEUMATICS, when speaking of bellows. They will there see very valid reasons, we apprehend, for thinking that the resistances must increase more slowly than the squares of the velocities.

It being found, then, that $V\sqrt{s}$ is not equal to a constant quantity $\sqrt{mg}$, it becomes necessary to investigate some quantity depending on $\sqrt{s}$, or, as it is called, some function of $\sqrt{s}$ which shall render $\sqrt{mg}$ a constant quantity. Let X be this function of $\sqrt{s}$, so that we shall always have VX equal to the constant quantity $\sqrt{mg}$, or $\frac{\sqrt{mg}}{X}$ equal to the actual velocity V of a pipe or channel which is in train.

Mr Buat, after many trials and reflections, the chief of which will be mentioned by and by, found a value of X which corresponded with a vast variety of slopes and velocities, from motions almost imperceptible, in a bed nearly horizontal, to the greatest velocities which could be produced by gravity alone in a vertical pipe; and when he compared them together, he found a very discernible relation between the resistances and the magnitude of the section; that is, that in two channels which had the same slope, and the same propelling force, the velocity was greatest in the channel which had the greatest section relative to its border. This may reasonably be expected. The resistances arise from the mutual action of the water and this border. The water immediately contiguous to it is retarded, and this retards the next, and so on. It is to be expected, therefore, that if the border, and the velocity, and the slope, be the same, the diminution of this velocity will be so much the less as it is to be shared among a greater number of particles; that is, as the area of the section is greater in proportion to the extent of its border. The diminution of the general or medium velocity must be less in a cylindrical pipe than in a square one of the same area, because the border of the section is less.

It appears evident, that the resistance of each particle is in the direct proportion of the whole resistance, and the inverse proportion of the number of particles which receive equal shares of it. It is therefore directly as the border, and inversely as the section. Therefore, in the expression $\frac{V^2}{m}$ which we have given for the resistance, the quantity m cannot be constant, except in the same channel; and in different channels it must vary along with the relation of the section to its border, because the resistances diminish in proportion as this relation increases.

Without attempting to discover this relation by theoretical examination of the particular motions of the various filaments, Mr Buat endeavoured to discover it by a comparison of experiments. But this required some manner of stating this proportion between the augmentation of the section and the augmentation of its border.

His statement is this: he reduces every section to a rectangular parallelogram of the same area, and having its base equal to the border unfolded into a straight line. The product of this base by the height of the rectangle will be equal to the area of the section. Therefore this height will be a representative of this valuable ratio of the section to its border (we do not mean that there is any ratio between a surface and a line: but the ratio of section to section is different from that of border to border; and it is the ratio of these ratios which is thus expressed by the height of this

T ory.

rectangle). If S be the section, and B the border, $\frac{S}{B}$ is evidently a line equal to the height of this rectangle. Every section being in this manner reduced to a rectangle, the perpendicular height of it may be called the HYDRAULIC MEAN DEPTH of the section, and may be expressed by the symbol d. Buat calls it the mean radius. If the channel be a cylindrical pipe, or an open half cylinder, it is evident that d is half the radius. If the section is a rectangle, whose width is w and height h, the mean depth is $\frac{w\,h}{w+2h}$, &c. In general, if q represent the proportion of the breadth of a rectangular canal to its depth, that is, if q be made $= \frac{w}{h}$, we shall have $d = \frac{w}{q+2}$, or $d = \frac{q\,h}{q+2}$.

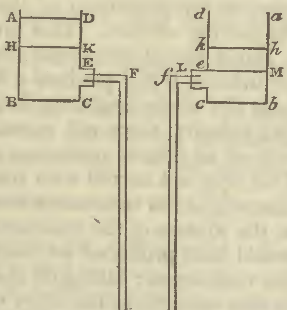
Now, since the resistances must augment as the proportion of the border to the section augments, m in the formulas $\frac{V^2}{w} = \frac{g}{s}$ and $V\sqrt{s} = \sqrt{mg}$ must follow the proportions of d, and the quantity $\sqrt{mg}$ must be proportional to $\sqrt{d}$, for different channels, and $\frac{\sqrt{mg}}{\sqrt{d}}$ should be a constant quantity in every case.

A sp ious objec on

Our author was aware, however, of a very specious objection to the close dependence of the resistance on the extent of the border, and that it might be said that a double border did not occasion a double resistance, unless the pressure on all the parts was the same. For it may be naturally, and it is generally, supposed, that the resistance will be greater when the pressure is greater. The friction, or resistance analogous to friction, may therefore be greater on an inch of the bottom than on an inch of the sides; but M. d'Alembert and many others have demonstrated, that the paths of the filaments will be the same whatever be the pressures. This might serve to justify our ingenious author; but he was determined to rest every thing on experiment. He therefore made an experiment on the oscillation of water in syphons, which we have repeated in the following form, which is affected by the same circumstances, and is susceptible of much greater precision, and of more extensive and important application.

obvia by an ex ri- ment the os la- tion water syph

Fig. 9.



The two vessels ABCD, *abcd* were connected by the syphon EFG*gfe*, which turned round in the short tubes E and *e*, without allowing any water to escape; the axis of these tubes being in one straight line. The vessels were about ten inches deep, and the branches FG, *fg* of the syphon were about five feet long. The vessels were set on two tables of equal height, and (the hole *e* being stopped) the vessel ABCD, and the whole syphon, were filled with water, and water was poured into the vessel *abcd* till it stood at a certain height LM. The syphon was then turned into a horizontal position, and the plug drawn out of *e*, and the time carefully noted which the water employed in rising to the level HK *kh* in both vessels. The whole apparatus was now inclined so that the water ran back into ABCD. The syphon was now put in a vertical position, and the experiment was repeated. No sensible or regular difference was observed in the time. Yet in this experiment the pressure on the part G*g* of the syphon was more than six times greater than before. As it was thought that the friction on this small part (only six inches) was too small a portion of the whole obstruction, various additional obstructions were put into this part of the syphon, and it was even lengthened to nine feet; but still no remarkable difference was observed. It was even thought that the times were less when the syphon was vertical.

Theory.

The resistance depends chiefly on the relation between the section and its border.

Thus M. de Buat's opinion is completely justified; and he may be allowed to assert, that the resistance depends chiefly on the relation between the section and its border; and that $\frac{\sqrt{mg}}{\sqrt{d}}$ should be a constant quantity.

To ascertain this point was the object of the next series of experiments; to see whether this quantity was really constant, and, if not, to discover the law of its variation, and the physical circumstances which accompanied the variations, and may therefore be considered as their causes. A careful comparison of a very great number of experiments, made with the same slope, and with very different channels and velocities, showed that $\sqrt{mg}$ did not follow the proportion of $\sqrt{d}$, nor of any power of $\sqrt{d}$. This quantity $\sqrt{mg}$ increased by smaller degrees in proportion as $\sqrt{d}$ was greater. In very great beds $\sqrt{mg}$ was nearly proportional to $\sqrt{d}$; but in smaller channels, the velocities diminished much more than $\sqrt{d}$ did. Casting about for some way of accommodation, M. Buat considered, that some approximation at least would be had by taking off from $\sqrt{d}$ some constant small quantity. This is evident: for such a diminution will have but a trifling effect when $\sqrt{d}$ is great, and its effect will increase rapidly when $\sqrt{d}$ is very small. He therefore tried various values for this subtraction, and compared the results with the former experiments; and he found, that if in every case $\sqrt{d}$ be diminished by one tenth of an inch, the calculated discharges would agree very exactly with the experiment. Therefore, instead of $\sqrt{d}$, he makes use of $\sqrt{d} - 0{\cdot}1$, and finds this quantity always proportional to $\sqrt{mg}$, or finds that $\frac{\sqrt{mg}}{\sqrt{d} - 0{\cdot}1}$ is a constant quantity, or very nearly so. It varied from 297 to 287 in all sections, from that of a very small pipe to that of a little canal. In the large sections of canals and rivers it diminished still more, but never was less than 256.

The result agreeable to our distinctest notions of the action of water and its bed,

This result is very agreeable to the most distinct notions that we can form of the mutual actions of the water and its bed. We see that when the motion of water is obstructed by a solid body, which deflects the passing filaments, the disturbance does not extend to any considerable distance on the two sides of the body. In like manner, the small disturbances, and imperceptible curvilineal motions, which are occasioned by the infinitesimal inequalities of the channel, must extend to a very small distance indeed from the sides and bottom of the channel. We know, too, that the mutual adhesion or attraction of water for the solid bodies which are moistened by it extends to a very small distance, which is probably the same, or nearly so, in all cases. M. Buat observed, that a surface of twenty-three square inches, applied to the surface of stagnant water, lifted 1601 grains; another of $5\frac{1}{2}$ square inches lifted 365; this was at the rate of sixty-five grains per inch nearly, making a column of about one sixth of an inch high. Now this effect is very much analogous to a real contraction of the capacity of the channel. The water may be conceived as nearly stagnant to this small distance from the border of the section. Or, to speak more accurately, the diminution of the progressive velocity occasioned by the friction and adhesion of the sides decreases very rapidly as we recede from the sides, and ceases to be sensible at a very small distance.

and confirmed by experiment.

The writer of this article[1] verified the observation by a very simple and instructive experiment. He was making experiments on the production of vortices, in the manner suggested by Sir Isaac Newton, by whirling a very accurate and smoothly polished cylinder in water; and he found that the rapid motion of the surrounding water was confined to an exceedingly small distance from the cylinder, and it was not till after many revolutions that it was sensible even at the distance of half an inch. We may, by the way, suggest this as the best form of experiments for examining the resistances of pipes. The motion excited by the whirling cylinder in the stagnant water is equal and opposite to the motion lost by water passing along a surface equal to that of the cylinder with the same velocity. Be this as it may, we are justified in considering, with M. Buat, the section of the stream as thus diminished by cutting off a narrow border all round the touching parts, and supposing that the motion and discharge is the same as if the square root of the mean depth of the section were diminished by a small quantity, nearly constant. We see, too, that the effect of this must be insensible in great canals and rivers; so that, fortunately, its quantity is best ascertained by experiments made with small pipes. This is attended with another conveniency, in the opinion of M. Buat, namely, that the effect of viscidity is most sensible in great masses of water in slow motion, and is almost insensible in small pipes, so as not to disturb these experiments. We may therefore assume 297 as the general value of $\frac{\sqrt{mg}}{\sqrt{d}-0{\cdot}1}$.[2]

Since we have $\frac{\sqrt{mg}}{\sqrt{d}-0{\cdot}1}=297$, we have also $m=\frac{297^2}{g}(\sqrt{d}-0{\cdot}1)^2, =\frac{88209}{362}(\sqrt{d}-0{\cdot}1)^2, =243{\cdot}7\,(\sqrt{d}-0{\cdot}1)^2$. This we may express by $n\,(\sqrt{d}-0{\cdot}1)^2$. And thus, when we have expressed the quantity of friction by $\frac{V^2}{m}$, the quantity m is variable, and its general value is $\frac{V^2}{n(\sqrt{d}-0{\cdot}1)^2}$, in which n is an invariable abstract number equal to 243·7, given by the nature of the resistance which water sustains from its bed, and which indicates its intensity.

And, lastly, since $m=n\,(\sqrt{d}-0{\cdot}1)^2$, we have $\sqrt{mg}=\sqrt{ng}\,(\sqrt{d}-0{\cdot}1)$, and the expression of the velocity V, which water acquires and maintains along any channel whatever, now becomes $V=\frac{\sqrt{ng}\,(\sqrt{d}-0{\cdot}1)}{X}$, or $\frac{297(\sqrt{d}-0{\cdot}1)}{X}$, in which X is also a variable quantity, depending on the slope of the surface or channel, and expressing the accelerating force which, in the case of water in train, is in equilibrio with the resistances expressed by the numerator of the fraction.

Law of acceleration investigated.

Having so happily succeeded in ascertaining the variations of resistance, let us accompany M. Buat in his investigation of the law of acceleration, expressed by the value of X.

Experience, in perfect agreement with any distinct opinions that we can form on this subject, had already shown him that the resistances increased in a slower ratio than that of the squares of the velocities, or that the velocities increased slower than $\sqrt{s}$. Therefore, in the formula $V=\frac{\sqrt{ng}\,(\sqrt{d}-0{\cdot}1)}{X}$, which, for one channel, we may express thus, $V=\frac{A}{X}$, we must admit that X is sensibly equal to $\sqrt{s}$ when the slope is very small or s very great. But, that we may accurately express the velocity in proportion as the slope augments, we must have X less than $\sqrt{s}$; and, moreover, $\frac{\sqrt{s}}{X}$ must increase as $\sqrt{s}$ diminishes. These conditions are necessary that our values of V, deduced from the formula $V=\frac{A}{X}$, may agree with the experiment.

In order to comprehend every degree of slope, we must particularly attend to the motion through pipes, because open canals will not furnish us with instances of exact TRAINS with great slopes and velocities. We can make pipes vertical. In this case $\frac{1}{s}$ is $\frac{1}{1}$, and the velocity is the greatest possible for a train by the action of gravity: but we can give greater velocities than this by increasing the head of water beyond what produces the velocity of the train.

Let AB (fig. 10) be a vertical tube, and let CA be the head competent to the velocity in the tube, which we suppose to be in train. The slope is 1, and the full weight of the column in motion is the precise measure of the resistance. The value of $\frac{1}{s}$, considered as a slope, is now a maximum; but, considered as expressing the proportion of the weight of the column in motion to the weight which is in equilibrio with the resistance, it may not be a maximum; it may surpass unity, and s may be less than 1. For if the vessel be filled to E, the head of water is increased, and will produce a greater velocity, and this will produce a greater resistance. The velocity being now greater, the head EF which imparts it must be greater than CA. But it will not be equal to EA, because the uniform velocities *are found* to increase faster than the square roots of the pressures. This is the general fact. Therefore F is above A, and the weight of the column FB, now employed to overcome the resistance, is greater than the weight of the column AB in motion. In such cases, therefore, $\frac{1}{s}$, greater than unity, is a sort of fictitious slope, and only represents the proportion of the resistance to the weight of the moving column. This proportion may surpass unity.

Fig. 10.

But it cannot be infinite: for, supposing the head of water infinite, if this produce a finite velocity, and we deduct from the whole height the height corresponding to this finite velocity, there will remain an infinite head, the measure of an infinite resistance produced by a finite velocity. This does not accord with the observed law of the velocities, where the resistances actually do not increase as fast as the squares of the velocities. Therefore an infinite head would have produced an infinite velocity, in opposition to the resistances: taking off the head of the tube, competent to this velocity, at the entry of the tube, which head would also be infinite, the remainder would in all probability be finite, balancing a finite resistance.

Therefore the value of s may remain finite, although the velocity be infinite; and this is agreeable to all our clearest notions of the resistances.

Adopting this principle, we must find a value of X which will answer all these conditions. 2. It must be sensibly proportional to $\sqrt{s}$, while s is great. It must always be less than $\surd s$. 3. It must deviate from the proportion of $\surd s$ so much the more as $\surd s$ is smaller. 4. It must not vanish when the velocity is infinite. 5. It must agree with a range of experiments with every variety of channel and of slope.

---

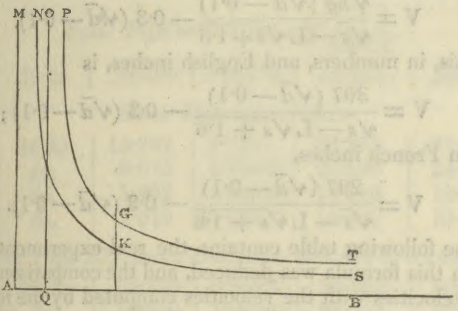
[1] The late Professor Robison of Edinburgh.

[2] In this formula, and in the subsequent part of the investigation, French inches are employed. For English inches the constant number is 307.

We shall understand the nature of this quantity X better by representing by lines the quantities concerned in forming it.

If the velocities were exactly as the square roots of the slopes, the equilateral hyperbola NKS (fig. 11) between

Fig. 11.



its asymptotes MA, AB, would represent the equation $V = \frac{A}{\surd s}$. The values of $\surd s$ would be represented by the abscissæ, and the velocities by the ordinates, and $V s = A$ would be the power of the hyperbola. But since these velocities are not sensibly equal to $\frac{A}{\surd s}$ except when $\surd s$ is very great, and deviate the more from this quantity as $\surd s$ is smaller, we may represent the velocities by the ordinates of another curve PGT, which approaches very near to the hyperbola, at a great distance from A along AB; but separates from it when the abscissæ are smaller: so that if AQ represents that value of $\surd s$ (which we have seen may become less than unity) which corresponds to an infinite velocity, the line QO may be the asymptote of the new curve. Its ordinates are equal to $\frac{A}{X}$, while those of the hyperbola are equal to $\frac{A}{\surd s}$. Therefore the ratio of these ordinates, or $\frac{\surd s}{X}$, should be such that it shall be so much nearer to unity as $\surd s$ is greater, and shall surpass it so much the more as $\surd s$ is smaller.

To express X, therefore, as some function of $\surd s$ so as to answer these conditions, we see in general that X must be less than $\surd s$. And it must not be equal to any power of $\surd s$ whose index is less than unity, because then $\frac{\surd s}{X}$ would differ so much the more from unity as $\surd s$ is greater. Nor must it be any multiple of $\surd s$, such as $q \surd s$, for the same reason. If we make $X = \surd s - K$, K being a constant quantity, we may answer the first condition pretty well. But K must be very small, that X may not become equal to nothing, except in some exceedingly small value of $\surd s$. Now the experiments will not admit of this, because the ratio $\frac{\surd s}{\surd s - K}$ does not increase sufficiently to correspond with the velocities which we observe in certain slopes, unless we make K greater than unity, which again is inconsistent with other experiments. We learn from such canvassing that it will not do to make K a constant quantity. If we should make it any fractionary power of $\surd s$, it would make $X = 0$, that is, nothing, when s is $= 1$, which is also contrary to experience. It would seem, therefore, that nothing will answer for K but some power of $\surd s$ which has a variable index. The logarithm of $\surd s$ has this property. We may therefore try to make $X = \surd s - \log. \surd s$. Accordingly, if we try the equation $V = \frac{A}{\surd s - \text{hyp. log.} \surd s}$, we shall find a very great agreement with the experiments till the declivity becomes considerable, or about $\frac{1}{20}$, which is much greater than any river. But it will not agree with the velocities observed in some mill-courses, and in pipes of a still greater declivity, and gives a velocity that is too small; and in vertical pipes the velocity is not above one half of the true one. We shall get rid of most of these incongruities if we make K consist of the hyperbolic logarithm of $\surd s$ augmented by a small quantity; and by trying various values for this constant quantity, and comparing the results with experiment, we may hit on one sufficiently exact for all practical purposes.

M. de Buat, after repeated trials, found that he would have a very great conformity with experiment by making $K = \log. \sqrt{s + 1{\cdot}6}$, and that the velocities exhibited in his experiments would be very well represented by the formula $V = \frac{297 (\surd d - 0{\cdot}1)}{\surd s - L \sqrt{s + 1{\cdot}6}}$.

Mutual adhesion of the particles of water.

There is a circumstance which our author seems to have overlooked on this occasion, and which is undoubtedly of great effect in these motions, viz. the mutual adhesion of the particles of water. This causes the water which is descending (in a vertical pipe, for example) to drag more water after it, and thus greatly increases its velocity. We have seen an experiment in which the water issued from the bottom of a reservoir through a long vertical pipe having a very gentle taper. It was fifteen feet long, one inch diameter at the upper end, and two inches at the lower. The depth of the water in the reservoir was exactly one foot; in a minute there were discharged $2\frac{9}{10}$ cubic feet of water. It must therefore have issued through the hole in the bottom of the reservoir with the velocity of 8·85 feet per second. And yet we know that this head of water could not make it pass through the hole with a velocity greater than 6·56 feet per second. This increase must therefore have arisen from the cause we have mentioned, and is a proof of the great intensity of this force. We doubt not but that the discharge might have been much more increased by proper contrivances; and we know many instances in water-pipes where this effect is produced in a very great degree.

An actual case

The following case is very distinct. Water is brought into the town of Dunbar, in the county of Haddington, from a spring at the distance of about 3200 yards. It is conveyed along the first 1100 yards in a pipe of two inches diameter, and the declivity is 12 feet 9 inches; from thence the water flows in a pipe of $1\frac{1}{2}$ diameter, with a declivity of 44 feet three inches, making in all 57 feet. When the work was carried as far as the two-inch pipe reached, the discharge was found to be 27 Scotch pints, of $103\frac{1}{2}$ cubic inches each, in a minute. When it was brought into the town, the discharge was 28. Here it is plain that the descent along the second stretch of the pipe could derive no impulsion from the first. This was only able to supply 27 pints, and to *deliver* it into a pipe of equal bore. It was not equivalent to the forcing it into a smaller pipe, and almost doubling its velocity. It must therefore have been *dragged* into this smaller pipe by the weight of what was descending along it, and this water was exerting a force equivalent to a head of 16 inches, increasing the velocity from 14 to about 28.

It must be observed, that if this formula be just, there can be no declivity so small that a current of water will not

Theory.

proves that the smallest declivity will produce a current.

take place in it. And accordingly none has been observed in the surface of a stream when this did not happen. But it also should happen with respect to any declivity of bottom. Yet we know that water will hang on the sloping surface of a board without proceeding further. The cause of this seems to be the adhesion of the water, combined with its viscidity. The viscidity of fluid presents a certain force which must be overcome before any current can take place.

A series of important experiments were made by our author in order to ascertain the relation between the velocity at the surface of any stream and that at the bottom. These are curious and valuable on many accounts. One circumstance deserves our notice here, viz. that *the differences between the superficial and bottom velocities of any stream are proportional to the square roots of the superficial velocities.* From what has been already said on the gradual diminution of the velocities among the adjoining filaments, we must conclude that the same rule holds good with respect to the velocity of separation of two filaments immediately adjoining. Hence we learn that this velocity of separation is in all cases indefinitely small, and that we may, without danger of any sensible error, suppose it a constant quantity in all cases.

A constant part of the accelerating force employed in overcoming the viscidity, &c.

We think, with our ingenious author, that on a review of these circumstances, there is a constant or invariable portion of the accelerating force employed in overcoming this viscidity, and producing this mutual separation of the adjoining filaments. We may express this part of the accelerating force by a part $\frac{1}{S}$ of that slope which constitutes the whole of it. If it were not employed in overcoming this resistance, it would produce a velocity which (on account of this resistance) is not produced, or is lost. This would be $\frac{A}{\sqrt{S}-L\sqrt{S}}$. This must therefore be taken from the velocity exhibited by our general formula. When thus corrected, it would become $V=(\sqrt{d}-0{\cdot}1)\left(\frac{\sqrt{ng}}{\sqrt{s}-L\sqrt{s+1{\cdot}6}}-\frac{\sqrt{ng}}{\sqrt{S}-L\sqrt{S}}\right)$. But as the term $\frac{\sqrt{ng}}{\sqrt{S}-L\sqrt{S}}$ is compounded only of constant quantities, we may express it by a single number. This has been collected from a scrupulous attention to the experiments (especially in canals and great bodies of water moving with very small velocities, in which case the effects of viscidity must become more remarkable), and it appears that it may be valued at $\sqrt{0{\cdot}09}$ inch, or 0·3 inch very nearly.

From the whole of the foregoing considerations, drawn from nature, supported by such reasonings as our most distinct notions of the internal motions will admit, and authorized by a very extensive comparison with experiment, we are now in a condition to conclude a complete formula, expressive of the uniform motion of water, and involving every circumstance which appears to have any share in the operation.

Therefore, let

Formula expressing the uniform motion of water.

V represent the mean velocity, in inches per second, of any current of water, running uniformly, or which is IN TRAIN, in a pipe or open channel, whose section, figure, and slope, are constant, but its length indefinite.

d The hydraulic mean depth, that is, the quotient arising from dividing the section of the channel, in square inches, by its border, expressed in linear inches.

s The reciprocal of the slope of the pipe, or of the surface of the current. It is the denominator of the fraction expressing this slope, the numerator being always unity; and is had by dividing the expanded length of the pipe or channel by the difference of height of its two extremities.

g The velocity (in inches per second) which a heavy body acquires by falling during one second.

n An abstract constant number, determined by experiment to be 243·7.

L The hyperbolic logarithm of the quantity to which it is prefixed, and is had by multiplying the common logarithm of that quantity by 2·3026.

We shall have in every instance

$$V=\frac{\sqrt{ng}\,(\sqrt{d}-0{\cdot}1)}{\sqrt{s}-L\sqrt{s+1{\cdot}6}}-0{\cdot}3\,(\sqrt{d}-0{\cdot}1).$$

This, in numbers, and English inches, is

$$V=\frac{307\,(\sqrt{d}-0{\cdot}1)}{\sqrt{s}-L\sqrt{s+1{\cdot}6}}-0{\cdot}3\,(\sqrt{d}-0{\cdot}1);$$

and in French inches,

$$V=\frac{297\,(\sqrt{d}-0{\cdot}1)}{\sqrt{s}-L\sqrt{s+1{\cdot}6}}-0{\cdot}3\,(\sqrt{d}-0{\cdot}1).$$

The following table contains the real experiments from which this formula was deduced, and the comparison of the real velocities with the velocities computed by the formula. It consists of two principal sets of experiments. The first are those made on the motion of water in pipes. The second are experiments made on open canals and rivers. In the first set, column 1st contains the number of the experiment; 2d, the length of the tube; 3d, the height of the reservoir; 4th, the values of *s*, deduced from columns second and third; 5th gives the observed velocities; and 6th, the velocities calculated by the formula.

In the second set, column 2d gives the area of the section of the channel; 3d, the border of the canal or circumference of the section, deducting the horizontal width, which sustains no friction; 4th, the square root $\sqrt{d}$ of the hydraulic mean depth; 5th, the denominator *s* of the slope; 6th, the observed mean velocities; and 7th, the mean velocities by the formula. In the last ten experiments on large canals and a natural river, the 6th column gives the observed velocities at the surface.[1]

The theory a well-founded probability.

The comparison must be acknowledged to be most satisfactory, and shows the great penetration and address of the author, in so successfully sifting and appreciating the share which each co-operating circumstance has had in producing the very intricate and complicated effect. It adds some weight to the principles on which he has proceeded in this analysis of the mechanism of hydraulic motion, and must give us great confidence in a theory so fairly established on a very copious induction. The author offers it only as a rational and well-founded probability. To this character it is certainly entitled; for the suppositions made in it are agreeable to the most distant notions we can form of these internal motions. And it must always be remembered, that the investigation of the formula, although it be rendered somewhat more perspicuous by thus having recourse to those motions, has no dependence on the truth of the principles. For it is, in fact, nothing but a classification of experiments, which are grouped together by some one circumstance of slope, velocity, form of section, &c. in order to discover the law of the changes which are induced by a variation of the circumstances which do not resemble. The procedure is precisely similar to that of the astronomer when he deduces the elements of an orbit from a multitude of observations. This was the task of M. de Buat; and he candidly and modestly informs us, that the finding out analytical forms of expression which would exhibit those changes was the work of Mr Benezech de St Honore, a young officer of engineers, and his colleague in the experimental course. It does honour to his skill and address; and we think the whole both a pretty and instructive specimen of the method of discovering the laws of nature in the midst of complicated phenomena. Daniel Bernoulli first gave the rules of this method, and they have been greatly improved by Lambert, Condorcet, and De la Grange. Mr Coulomb has given some excellent examples of their application to the discovery of the laws of friction, of magnetical and electrical attraction, &c. But this present work is the most perspicuous and familiar of them all. It is the empirical method of generalising natural phenomena, and of deducing general rules, of which we can give no other demonstration but that they are faithful representations of matters of fact. We hope that others, encouraged by the success of M. de Buat, will follow this example, where public utility is preferred to a display of mathematical knowledge.

The ex riment highly luable.

Although the author may not have hit upon the precise *modus operandi*, we agree with him in thinking that nature seems to act in a way not unlike what is here supposed. At any rate, the range of experiments is so extensive, and so multifarious, that few cases can occur which are not included among them. The experiments will always retain their value (as we presume that they are faithfully narrated), whatever may become of the theory; and we are confident that the formula will give an answer to any question to which it may be applicable, infinitely preferable to the vague guess of the most sagacious and experienced engineer.

The ve city gi by the mula t large f ordinar works.

We must however observe, that as the experiments on pipes were all made with scrupulous care in the contrivance and execution of the apparatus, excepting only those of Mr Couplet on the main pipes at Versailles, we may presume that the formula gives the greatest velocities which can be expected. In ordinary works, where joints are rough or leaky, where drops of solder hang in the inside, where cocks intervene with deficient water-ways, where pipes have awkward bendings, contractions, or enlargements, and where they may contain sand or air, we should reckon on a smaller velocity than what results from our calculation; and we presume that an undertaker may with confidence promise four fifths of this quantity without any risk of disappointing his employer. We imagine that the actual performance of canals will be much nearer to the formula.

We have made inquiry after works of this kind executed in Britain, that we might compare them with the formula. But all our canals are locked and without motion; and we have only learned by an accidental information from Mr Watt, that a canal in his neighbourhood, which is eighteen feet wide at the surface, and seven feet at the bottom, and four feet deep, and has a slope of one inch in a quarter of a mile, runs with the velocity of seventeen inches per second at the surface, ten at the bottom, and fourteen in the middle. If we compute the motion of this canal by our formula, we shall find the mean velocity to be $13\frac{1}{3}$..

No river in the world has had its motion so much scrutinized as the Po about the end of the last century. It had been a subject of 100 years' continual litigation between the inhabitants of the Bolognese and the Ferrarese, whether the waters of the Rheno should be thrown into the Tronco de Venezia or Po Grande. This occasioned very numerous measures to be taken of its sections and declivity, and the quantities of water which it contained in its different states of fulness. But, unfortunately, the long-established methods of measuring waters which were in force in Lombardy, made no account of the velocity; and not all the entreaties of Castelli, Grandi, and other moderns, could prevail on the visitors in this process to deviate from the established methods. We have therefore no minute accounts of its velocity, though there are many rough estimates to be met with in that valuable collection published at Florence in 1723, of the writings on the motion of rivers. From them we have extracted the *only precise observations* which are to be found in the whole work.

serva-
ns on
e velo-
y of the

The Po Grande receives no river from Stellata to the sea, and its slope in that interval is found most surprisingly uniform, namely, six inches in the mile (reduced to English measure). The breadth in its great freshes is 759 feet at Lago Scuro, with a very uniform depth of thirty-one feet. In its lowest state (in which it is called *Po Magra*), its breadth is not less than 700, and its depth about ten and a half.

The Rheno has a uniform declivity from the Ponte Emilio to Vigarano of fifteen inches per mile. Its breadth in its greatest freshes is 189 feet, and its depth nine.

Signor Corrade in his report says, that in the state of the great freshes the velocity of the Rheno is most exactly four fifths of that of the Po.

Grandi says, that, according to many observations of his own, a great fresh in the Rheno employs twelve hours to come from Ponte Emilio to Vigarano, which is thirty miles. This is a velocity of forty-four inches per second. And, by Corrade's proportion, the velocity of the Po Grande must be fifty-five inches per second.

Montanari's observation gives the Po Magra a velocity of thirty-one inches per second.

Let us compare these velocities with the velocities calculated by Buat's formula.

The hydraulic mean depths d and D of the Rheno and Po in the great freshes, deduced from the above measures, are 98·6 and 344 inches; and their slopes s and S are $\frac{1}{4223}$ and $\frac{1}{10360}$. This will give

$$\frac{307\,(\sqrt{\mathrm{D}}-0{\cdot}1)}{\sqrt{\mathrm{S}}-\mathrm{L}\sqrt{\mathrm{S}+1{\cdot}6}}-0{\cdot}3\,(\sqrt{\mathrm{D}}-0{\cdot}1)=52{\cdot}176 \text{ inches, and}$$

$$\frac{307\,(\sqrt{d}-0{\cdot}1)}{\sqrt{s}\,\mathrm{L}\sqrt{s+1{\cdot}6}}-0{\cdot}3\,(\sqrt{d}-0{\cdot}1)=46{\cdot}727 \text{ inches.}$$

These results differ very little from the velocities above mentioned. And if the velocity corresponding to a depth of thirty-one feet be deduced from that observed by Montanari in the Po Magra ten feet deep, on the supposition that they are in the proportion of $\sqrt{d}$, it will be found to be about fifty-three and a half inches per second.

ghly to
credit
the the-
r.

This comparison is therefore highly to the credit of the theory, and would have been very agreeable to M. de Buat, had he known it, as we hope it is to our readers.

We have collected many accounts of water-pipes, and made the comparisons, and we flatter ourselves that these have enabled us to improve the theory. They shall appear in their proper place; and we may just observe here, that the two-inch pipe, which we formerly spoke of as conveying the water to Dunbar, should have yielded only $25\frac{2}{3}$ Scotch pints per minute by the formula, instead of 27; a small error.

We have, therefore, no hesitation in saying, that this single formula of the uniform motion of water is one of the most valuable presents which natural science and the arts have received during the course of this century.

A table containing the values of $\frac{307}{\sqrt{s}-\mathrm{L}\sqrt{s+1{\cdot}6}}$ ready calculated for every declivity that can occur in water-pipes, canals, or rivers, is given in the article WATER-WORKS. Aided by this, which supersedes the only difficult part of the computation, a person can calculate the velocity for any proposed case in less than five minutes.

We have now established in some measure a THEORY OF HYDRAULICS, by exhibiting a general theorem which expresses the relation of the chief circumstances of all such motions as have attained a state of permanency, in so far as this depends on the magnitude, form, and slope of the channel. This permanency we have expressed by the term TRAIN, saying that the stream is *in train*.

We proceed to consider the subordinate circumstances contained in this theorem; such as, 1st, The forms which nature or art may give to the bed of a running stream, and the manner of expressing this form in our theorem. 2d, The gradations of the velocity, by which it decreases in the different filaments, from the axis or most rapid filament to the border; and the connection of this with the mean velocity, which is expressed by our formula. 3d, Having acquired some distinct notions of this, we shall be able to see the manner in which undisturbed nature works in forming the beds of our rivers, the forms which she affects, and which we must imitate in all their local modifications, if we would secure that permanency which is the evident aim of all her operations. We shall here learn the mutual action of the current and its bed, and the circumstances which insure the stability of both. These we may call the *regimen* or the *conservation* of the stream, and may say that it is *in regimen*, or *in conservation*. This has a relation, not to the dimensions and the slope alone, or to the accelerating force and the resistance arising from mere inertia; it respects immediately the tenacity of the bed, and is different from *the train*.

Regimen
of streams,
what.

4th, These pieces of information will explain the deviation of rivers from the rectilineal course, the resistance occasioned by these deviations, and the circumstances on which the regimen of a winding stream depends.

§ 1. *Of the Forms of the Channel.*

The semi-
circular
form most
favourable
to motion,

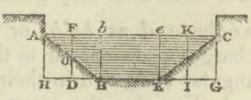
The numerator of the fraction which expresses the velocity of a river in train has $\sqrt{d}$ for one of its factors. That form, therefore, is most favourable to the motion which gives the greatest value to what we have called the hydraulic mean depth d. This is the prerogative of the semicircle, and here d is equal to half the radius; and all other figures of the same area are the more favourable, as they approach nearer to a semicircle. This is the form, therefore, of all conduit-pipes, and should be taken for aqueducts which are built of masonry. Ease and accuracy of execution, however, have made engineers prefer a rectangular form; but neither of these will do for a channel formed out of the ground. We shall soon see that the semicircle is incompatible with a regimen; and if we proceed through the regular polygons, we shall find that the half hexagon is the only one which has any pretensions to a regimen; yet experience shows us, that even its banks are too steep for almost any soil. A dry earthen bank, not bound together by grass roots, will hardly stand with a slope of forty-five degrees; and a canal which conveys running waters will not stand with this slope. Banks whose base is to their height as four to three will stand very well in moist soils, and this is a slope very usually given. This form is even affected in the spontaneous operations of nature, in the channels which she digs for the rills and rivulets in the higher and steeper grounds.

but incom-
patible
with regi-
men.

Banks that
stand best.

This form has some mathematical and mechanical properties which entitle it to some further notice. Let ABEC (fig. 12) be such a trapezium, and AHGC the rectangle of equal width and depth. Bisect HB and EG by the verticals FD and KI, and draw the verticals bB, eE. Because AH : HB = 3 : 4, we have AB = 5, and BD = 2, and FD = 3, and BD + DF = BA. From these premises it follows, that the trapezium ABEC has the same area with the rectangle FDIK; for HB being bisected in D, the triangles AOF, BOD are equal. Also the border ABEC, which is touched by the passing stream, is equal to FDIK.

Fig. 12.



Therefore the mean depth, which is the quotient of the area divided by the border, is the same in both; and this is the case, whatever is the width BE at the bottom, or even though there be no rectangle such as *b*BE*e* interposed between the slant sides.

Best form of a channel.

Of all rectangles, that whose breadth is twice the height, or which is half of a square, gives the greatest mean depth. If, therefore, FK be double of FD, the trapezium ABEC, which has the same area, will have the largest mean depth of any such trapezium, and will be the best form of a channel for conveying running waters. In this case, we have AC = 10, AH = 3, and BE = 2. Or we may say that the best form is a trapezium, whose bottom width is $\frac{2}{3}$ of the depth, and whose extreme width is $\frac{10}{3}$. This form approaches very near to that which the torrents in the hills naturally dig for themselves in uniform ground, where their action is not checked by stones which they lay bare, or which they deposit in their course. This shows us, and it will be fully confirmed by and by, that the channel of a river is not a fortuitous thing, but has a relation to the consistency of the soil and velocity of the stream.

A rectangle, whose breadth is $\frac{4}{3}$ of the depth of water, will therefore have the same depth with a triangle whose surface width is $\frac{8}{3}$ of its vertical depth; for this is the dimensions when the rectangle *b*BE*e* is taken away.

Let A be the area of the section of any channel, w its width (when rectangular), and h its depth of water. Then what we have called its mean depth, or d, will be $\frac{A}{w+2h}$, $= \frac{wh}{w+2h}$. Or if q expresses the ratio of the width to the depth of a rectangular bed, that is, if $q = \frac{w}{h}$, we have a very simple and ready expression for the mean depth, either from the width or depth. For $d = \frac{w}{q+2}$, or $d = \frac{qh}{q+2}$.

Therefore, if the depth were infinite, and the width finite, we should have $d = \frac{w}{2}$; or if the width be infinite, and the depth finite, we have $d = h$. And these are the limits of the values of d; and therefore in rivers whose width is always great in comparison of the depth, we may without much error take their real depth for their hydraulic mean depth. Hence we derive a rule of easy recollection, and which will at all times give us a very near estimate of the velocity and expense of a running stream, viz. *that the velocities are nearly as the square roots of the depths.* We find this confirmed by many experiments of Michelotti.

Estimate of the expense of a running stream.

Also, when we are allowed to suppose this ratio of the velocities and depths, that is, in a rectangular canal of great breadth and small depth, we shall have the quantities discharged nearly in the proportion of the cubes of the velocities. For the quantity discharged d is as the velocity and area jointly, that is, as the height and velocity jointly, because when the width is the same the area is as the height. Therefore, we have $d \doteq hv$. But, by the above remark, $h \doteq v^2$. Therefore, $d \doteq v^3$; and this is confirmed by the experiments of Bossut, vol. ii. 236. Also, because d is as vh, when w is constant, and by the above remark (allowable when w is very great in proportion to h) v is as $\sqrt{h}$, we have d as $h\sqrt{h}$, or $h^{\frac{3}{2}}$, or the squares of the discharges proportional to the cubes of the heights in rectangular beds, and in their corresponding trapeziums.

The

Rules finding dimen

1. Knowing the mean depth and the proportion of the width and real depth, we can determine the dimensions of the bed, and we have $w = qd + 2d$, and $h = d + \frac{2d}{q}$.

2. If we knew the area and mean depth, we can in like manner find the dimensions, that is, w and h; for $A = wh$, and $d = \frac{wh}{w+2h}$; therefore $w = \pm\sqrt{\frac{A^2}{4d^2} - 2A} + \frac{A}{2d}$.

3. If d be known, and one of the dimensions be given, we can find the other; for $d = \frac{wh}{w+2h}$ gives $w = \frac{2hd}{h-d}$, and $h = \frac{wd}{w-2d}$.

mean depth

4. If the velocity V and the slope s for a river in train be given, we can find the mean depth; for $V = \left(\frac{307}{\sqrt{s} - L\sqrt{s+1{\cdot}6}} - 0{\cdot}3\right)(\sqrt{d} - 0{\cdot}1)$. Whence we deduce $\sqrt{d} - 0{\cdot}1 = \frac{V}{\frac{307}{\sqrt{s} - L\sqrt{s+1{\cdot}6})} - 0{\cdot}3}$, and $\sqrt{d} =$ to this quantity $+ 0{\cdot}1$.

slope

5. We can deduce the slope which will put in train a river whose channel has given dimensions. We make $\frac{307(\sqrt{d} - 0{\cdot}1)}{V + 0{\cdot}3(\sqrt{d} - 0{\cdot}1)} = \sqrt{s}$. This should be $= \sqrt{s} - L\sqrt{s+1{\cdot}6}$, which we correct by trials, which will be exemplified when we apply these doctrines to practice.

Having thus established the relation between the different circumstances of the form of the channel to our general formula, we proceed to consider,

§ 2. *The Gradations of Velocity from the middle of the Stream to the sides.*

The knowledge of this is necessary for understanding the regimen of a river; for it is the velocity of the filaments in contact with the bed which produces any change in it, and occasions any preference of one to another in respect of regimen or stability. Did these circumstances not operate, the water, true to the laws of hydraulics, and confined within the bounds which have been assigned them, would neither enlarge nor diminish the area of the channel. But this is all that we can promise of waters perfectly clear, running in pipes or hewn channels. But rivers, brooks, and smaller streams, carry along waters loaded with mud or sand, which they deposit wherever their velocity is checked; and they tear up, on the other hand, the materials of the channel wherever their velocity is sufficiently great. Nature, indeed, aims continually at an equilibrium, and works without ceasing to perpetuate her own performances, by establishing an equality of action and re-action, and proportioning the forms and direction of the motions to her agents, and to local circumstances. Her work is slow but unceasing; and what she cannot accomplish in a year she will do in a century. The beds of our rivers have acquired some stability, because they are the labour of ages; and it is to time that we owe those deep and wide valleys which receive and confine our rivers in channels, which are now consolidated, and with slopes which have been gradually moderated, so that they no longer either ravage our habitations or confound our boundaries. Art may imitate nature, and, by directing her operations (which she still carries on according to her own imprescriptible laws) according to our views, we can hasten her progress, and accomplish our purpose, during the short period of human life. But we can do this only by studying the unalterable laws of mechanism. These are presented to us by spontaneous nature. Fre-

Natur be imi in mal artific stream

quently we remain ignorant of their foundation; but it is not necessary for the prosperity of the subject that he have the talents of the senator; he can profit by the statute without understanding its grounds. It is so in the present instance. We have not as yet been able to infer the law of retardation observed in the filaments of a running stream from any sound mechanical principle. The problem, however, does not appear beyond our powers, if we assume, with Sir Isaac Newton, that the velocity of any particular filament is the arithmetical mean between those of the filaments immediately adjoining. We may be assured, that the filament in the axis of an inclined cylindrical tube, of which the current is in train, moves the fastest, and that all those in the same circumference round it are those which glide along the pipe. We may affirm the same thing of the motions in a semicylindrical inclined channel conveying an open stream. But even in these we have not yet demonstrated the ratio between the extreme velocities, nor in the different circles. This must be decided experimentally.

And here we are under great obligations to M. de Buat. He has compared the velocities in the axes of a prodigious number and variety of streams, differing in size, form, slope, and velocity, and has computed in them all the mean velocities, by measuring the quantities of water discharged in a given time. His method of measuring the bottom velocity was simple and just. He threw in a gooseberry, as nearly as possible of the same specific gravity with the water. It was carried along the bottom almost without touching it. See Resistance of Fluids, p. 180.

He discovered the following laws: 1. In small velocities the velocity in the axis is to that at the bottom in a ratio of considerable inequality. 2. This ratio diminishes as the velocity increases, and in very great velocities approaches to the ratio of equality. 3. What was most remarkable was, that neither the magnitude of the channel, nor its slope, had any influence in changing this proportion, while the mean velocity remained the same. Nay, though the stream ran on a channel covered with pebbles or coarse sand, no difference worth noticing was to be observed from the velocity over a polished channel. 4. And if the velocity in the axis is constant, the velocity at the bottom is also constant, and is not affected by the depth of water or magnitude of the stream. In some experiments the depth was thrice the width, and in others the width was thrice the depth. This changed the proportion of the magnitude of the section to the magnitude of the rubbing part, but made no change on the ratio of the velocities. This is a thing which no theory could point out.

Another most important fact was also the result of his observation, viz. that *the mean velocity in any pipe or open stream is the arithmetical mean between the velocity in the axis and the velocity at the sides of a pipe or bottom of an open stream.* We have already observed, that the ratio of the velocity in the axis to the velocity at the bottom diminished as the mean velocity increased. This variation he was enabled to express in a very simple manner, so as to be easily remembered, and to enable us to tell any one of them by observing another.

If we take unity from the square root of the superficial velocity, expressed in inches, the square of the remainder is the velocity at the bottom; and the mean velocity is the half sum of these two. Thus, if the velocity in the middle of the stream be 25 inches per second, its square root is five; from which if we take unity, there remains four. The square of this, or 16, is the velocity at the bottom, and $\frac{25 + 16}{2}$, or $20\frac{1}{2}$, is the mean velocity.

This is a very curious and most useful piece of information. The velocity in the middle of the stream is the easiest measured of all, by any light small body floating down; and the mean velocity is the one which regulates the train, the discharge, the effect on machines, and all the most important consequences.

Theory.

We may express this by a formula of most easy recollection. Let V be the mean velocity, v the velocity in the axis, and u the velocity at the bottom; we have

expressed by a formula.

$$u = (\sqrt{v} - 1)^2, \text{ and } V = \frac{v + u}{2}.$$

Also $v = (\sqrt{V - \frac{1}{4}} + \frac{1}{2})^2$, and $v = (\sqrt{u} + 1)^2$.

$$V = (\sqrt{v} - \tfrac{1}{2})^2 + \tfrac{1}{4}, \text{ and } V = (\sqrt{u} + \tfrac{1}{2})^2 + \tfrac{1}{4}.$$

$$u = (\sqrt{v} - 1)^2, \text{ and } u = (\sqrt{V - \tfrac{1}{4}} - \tfrac{1}{2})^2.$$

Also $v - u = 2\sqrt{V - \frac{1}{4}}$ and $v - V, = V - u, = \sqrt{V - \frac{1}{4}}$; that is, the difference between these velocities increases in the ratio of the square roots of the mean velocities diminished by a small constant quantity.[1]

This may perhaps give the mathematicians some help in ascertaining the law of degradation from the axis to the sides. Thus, in a cylindrical pipe, we may conceive the current as consisting of an infinite number of cylindrical shells sliding within each other like the draw-tubes of a spy-glass. Each of these is in equilibrio, or as much accelerated by the one within it as it is retarded by the one without; therefore, as the *momentum* of each diminishes in the proportion of its diameter (the thickness being supposed the same in all), the velocity of separation must increase by a certain law from the sides to the axis. The magnitude of the small constant quantity here spoken of seems to fix this law.

Place of the mean velocity not discovered.

The place of the mean velocity could not be discovered with any precision. In moderate velocities it was not more than one fourth or one fifth of the depth distant from the bottom. In very great velocities it was sensibly higher, but never in the middle of the depth.

The knowledge of these three velocities is of great importance. The superficial velocity is easily observed, hence the mean velocity is easily computed. This multiplied by the section gives the expense; and if we also measure the expanded border, and then obtain the mean depth (or $\sqrt{d}$), we can, by the formula of uniform motion, deduce the slope, or, knowing the slope, we can deduce any of the other circumstances.

The following table of these three velocities will save the trouble of calculation in one of the most frequent questions of hydraulics.

Velocity in Inches.			Velocity in Inches.

The knowledge of the velocity at the bottom is of the greatest use for enabling us to judge of the action of the stream on its bed; and we shall now make some observations on this particular.

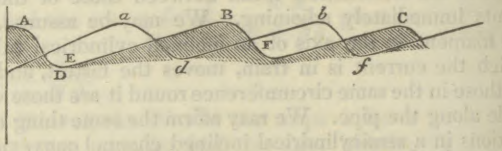
Operation of the stream on its bed,

Every kind of soil has a certain velocity consistent with the stability of the channel. A greater velocity would enable the waters to tear it up, and a smaller velocity would permit the deposition of more moveable materials from above. It is not enough, then, for the stability of a river, that the accelerating forces are so adjusted to the size and figure of its channel that the current may be in train: it must also be in equilibrio with the tenacity of the channel.

We learn from observation, that a velocity of three inches per second at the bottom will just begin to work upon fine clay fit for pottery, and however firm and compact it may be, it will tear it up. Yet no beds are more stable than clay when the velocities do not exceed this: for the water soon takes away the impalpable particles of the superficial clay, leaving the particles of sand sticking by their lower half in the rest of the clay, which they now protect, making a very permanent bottom, if the stream does not bring down gravel or coarse sand, which will rub off this very thin crust, and allow another layer to be worn off. A velocity of six inches will lift fine sand; eight inches will lift sand as coarse as linseed; twelve inches will sweep along fine gravel; twenty-four inches will roll along rounded pebbles an inch diameter; and it requires three feet per second at the bottom to sweep along shivery angular stones of the size of an egg.

The manner in which unwearied nature carries on some of these operations is curious, and deserves to be a little noticed. All must recollect the narrow ridges or wrinkles which are left on the sand by a temporary fresh or stream. They are observed to lie across the stream, and each ridge consists of a steep face AD, BF (fig. 13), which looks down the stream, and a gentler slope DB, FC, which connects this with the next ridge.

Fig. 13.



As the stream comes over the first steep AD, it is directed almost perpendicularly against the point E immediately below D, and thus it gets hold of a particle of coarse sand, which it could not have detached from the rest had it been moving parallel to the surface of it. It easily rolls it up the gentle slope EB; arrived there, the particle tumbles over the ridge, and lies close at the bottom of it at F, where it is protected by the little eddy, which is formed in the very angle; other particles lying about E are treated in the same way, and, tumbling over the ridge B, cover the first particle, and now protect it effectually from any farther disturbance. The same operation is going on at the bottom of each ridge. The brow or steep of the ridge gradually advances down the stream, and the whole set change their places, as represented by the line *adbf*; and after a certain time the particle which was deposited in F is found in an unprotected situation, as it was in E, and it now makes another step down the stream.

The Abbé Bossut found, that when the velocity of the stream was just sufficient for lifting the sand (and a small excess hindered the operation altogether), a ridge advanced about twenty feet in a day.

Since the current carries off the most moveable matters of the channel, it leaves the bottom covered with the remaining coarse sand, gravel, pebbles, and larger stones. To these are added many which come down the stream while it is more rapid, and also many which roll in from the sides as the banks wear away. All these form a bottom much more solid and immoveable than a bottom of the medium soil would have been. But this does not always maintain the channel in a permanent form, but frequently occasions great changes, by obliging the current, in the event of any sudden fresh or swell, to enlarge its bed, and even to change it altogether, by working to the right and to the left, since it cannot work downwards. It is generally from such accumulation of gravel and pebbles in the bottom of the bed that rivers change their channels.

It remains to ascertain, in absolute measures, the force which a current really exerts in attempting to drag along with it the materials of its channel; and which *will* produce this effect unless resisted by the inertia of these materials. It is therefore of practical importance to know this force.

Nor is it abstruse or difficult. For when a current is in train, the accelerating force is in equilibrio with the resistance, and is therefore its immediate measure. Now this accelerating force is precisely equal to the weight of the body of water in motion multiplied by the fraction which expresses the slope. The mean depth being equal to the quotient of the section divided by the border, the section is equal to the product of the mean depth multiplied by the border. Therefore, calling the border b, and the mean depth d, we have the section $= db$. The body of water in motion is therefore dbs (because s was the slant length of a part whose difference of elevation is 1), and the accelerating force is $dbs \times \frac{1}{s}$, or db. But if we would only consider this resistance as corresponding to an unit of the length of the channel, we must divide the quantity db by s, and the resistance is then $\frac{db}{s}$. And if we would consider the resistance only for an unit of the border, we must divide this expression by b; and thus this resistance (taking an inch for the unit) will be expressed for one square inch of the bed by the weight of a bulk of water which has a square inch for its base, and $\frac{d}{s}$ for its height. And lastly, if E be taken for any given superficial extent of the channel or bed, and F the obstruction, which we consider as a sort of friction, we shall have $F = \frac{Ed}{s}$.

Thus, let it be required to determine in pounds the resistance or friction on a square yard of a channel whose current is in train, which is ten feet wide, four feet deep, and has a slope of one foot in a mile. Here E is nine feet. Ten feet width and four feet depth give a section of forty feet. The border is eighteen feet. Therefore $d = \frac{40}{18} = 2{\cdot}2222$, and s is 5280. Therefore the friction is the weight of a column of water whose base is nine feet, and height $\frac{2{\cdot}2222}{5280}$, or nearly $3\frac{6}{10}$ ounces avoirdupois.

§ 3. *Settlement of the Beds of Rivers.*

He who looks with a careless eye at a map of the world, is apt to consider the rivers which ramble over its surface as a chance-medley disposition of the drainers which carry off the waters. But it will afford a most agreeable object to a considerate and contemplative mind to take it up in this very simple light; and, having considered the many ways in which the drenched surface might have been cleared of the superfluous waters, to attend particularly to the very way which nature has followed. In pursuing the troubled waters of a mountain torrent, or the pure streams which trickle from their bases, till he sees them swallowed up in the ocean, and in attending to the many varieties in their motions, he will be delighted with observing how the simple laws of mechanism are made so fruitful in good consequences, both by modifying the motions of the waters themselves, and also by inducing new forms on the surface of the earth, fitted for re-acting on the waters, and producing those very modifications of their motions which render them so beneficial. The permanent beds of rivers are by no means fortuitous gutters hastily scooped out by dashing torrents; but both they and the valleys through which they flow are the patient but unceasing labours of nature, prompted by goodness and directed by wisdom.

Whether we trace a river from the torrents which collect the superfluous waters of heaven, or from the springs which discharge what would otherwise be condemned to perpetual inactivity, each feeder is but a little rill, which could not ramble far from its scanty source among growing plants and absorbent earth, without being sucked up and evaporated, did it not meet with other rills in its course. When united, they form a body of water still inconsiderable, but much more able, by its bulk, to overcome the little obstacles to its motion; and the rivulet then moves with greater speed, as we have now learned. At the same time, the surface exposed to evaporation and absorption is diminished by the union of the rills. Four equal rills have only the surface of two when united. Thus the portion which escapes arrestment, and travels downward, is continually increasing. This is a happy adjustment to the other operations of nature. Were it otherwise, the lower and more valuable countries would be loaded with the passing waters in addition to their own surplus rains, and the immediate neighbourhood of the sea would be almost covered by the drains of the interior countries. But, fortunately, those passing waters occupy less room as they advance, and by this wise employment of the most simple means, not only are the superfluous waters drained off from our fertile fields, but the drains themselves become an useful part of the country by their magnitude. They become the habitation of a prodigious number of fishes, which share the Creator's bounty; and they become the means of mutual communication of all the blessings of cultivated society. The vague ramblings of the rivers scatter them over the face of the country, and bring them to every door. It is not even an indifferent circumstance, that they gather strength to cut out deep beds for themselves. By this means they cut open many springs. Without this, the produce of a heavy shower would make a swamp which would not dry up in many days. And it must be observed, that the same heat which is necessary for the vigorous growth of useful plants will produce a very copious evaporation. This must return in showers much too copious for immediate vegetation, and the overplus would be destructive. Is it not pleasant to contemplate this adjustment of the great operations of nature, so different from each other, that if chance alone directed the detail, it was almost an infinite odds that the earth would be uninhabitable?

Theory.

Their effect on the countries through which they pass.

But let us follow the waters in their operations, and note the face of the countries through which they flow. Attending to the breadth, the depth, and the slope of the valleys, we shall be convinced that their present situation is extremely different from what it was in ancient days; and that the valleys themselves are the works of the rivers, or at least of waters which have descended from the heights, loaded with all the lighter matters which they were able to bring away with them. The rivers now flow in beds which have a considerable permanency; but this has been the work of ages. This has given stability, both by filling up and smoothing the valleys, and thus lessening the changing causes, and also by hardening the beds themselves, which are now covered with aquatic plants, and lined with the stones, gravel, and coarser sand, out of which all the lighter matters have been washed away.

The surface of the high grounds is undergoing a continual change; and the ground on which we now walk is by no means the same which was trodden by our remote ancestors. The showers from heaven carry down into the valleys, or sweep along by the torrents, a part of the soil which covers the heights and steeps. The torrents carry this soil into the brooks, these deliver part of it into the great rivers, and these discharge this fertilizing fat of the earth into the sea, where it is swallowed up, and for ever lost for the purposes of vegetation. Thus the hillocks lose of their height, the valleys are filled up, and the mountains are laid bare and show their naked precipices, which formerly were covered over with flesh and skin, but now look like the skeleton of this globe. The low countries, raised and nourished for some time by the substance of the high lands, will go in their turn to be buried in the ocean; and then the earth, reduced to a dreary flat, will become an immense uninhabitable mass. This catastrophe is far distant, because this globe is in its youth, but it is not the less certain; and the united labours of the human race could not long protract the term.

But, in the mean time, we can trace a beneficent purpose, and a nice adjustment of seemingly remote circumstances. The grounds near the sources of all our rivers are indeed gradually stripped of their most fertile ingredi-

Theory.

Beneficence displayed in the changes they produce.

ents. But had they retained them for ages, the sentient inhabitants of the earth, or at least the nobler animals, with man at their head, would not thence have derived much advantage. The general laws of nature produce changes in our atmosphere which must ever render these great elevations unfruitful. That genial warmth, which is equally necessary for the useful plant as for the animal which lives on it, is confined to the lower grounds. The earth, which on the top of Mount Hæmus could only bring forth moss and dittany, when brought into the gardens of Spalatro produced pot-herbs so luxuriant, that Diocletian told his colleague Maximian that he had more pleasure in their cultivation than the Roman empire could confer. Thus nature not only provides us manure, but conveys it to our fields. She even keeps it safe in store for us till it shall be wanted. The tracts of country which are but newly inhabited by man, such as great part of America, and the newly-discovered regions of Terra Australis, are still almost occupied by marshes and lakes, or covered with impenetrable forests; and they would remain long enough in this state, if population, continually increasing, did not increase industry, and multiply the hands of cultivators along with their necessities. The Author of Nature was alone able to form the huge ridges of the mountains, to model the hillocks and the valleys, to mark out the courses of the great rivers, and give the first trace to every rivulet; but has left to man the task of draining his own habitation and the fields which are to support him, because this is a task not beyond his powers. It was therefore of immense advantage to him that those parts of the globe into which he has not yet penetrated should remain covered with lakes, marshes, and forests, which keep in store the juice of the earth, which the influence of the air and the vivifying warmth of the sun would have expended long ere now in useless vegetation, and which the rains of heaven would have swept into the sea, had they not been thus protected by their situation or their cover. It is therefore the business of man to open up these mines of hoarded wealth, and to thank the Author of all good, who has thus husbanded them for his use, and left them as a rightful heritage for those of after days.

The earth had not in the remote ages, as in our day, those great canals, those capacious voiders, always ready to drain off the rain-waters (of which only part is absorbed by the thirsty ground) and the pure waters of the springs from the foot of the hills. The rivers did not then exist, or were only torrents, whose waters, confined by the gulleys and glens, are searching for a place to escape. Hence arise those numerous lakes in the interior of great continents, of which there are still remarkable relics in North America, which in process of time will disappear, and become champaign countries. The most remote from the sea, unable to contain its waters, finds an issue through some gorge of the hills, and pours over its superfluous waters into a lower basin, which, in its turn, discharges its contents into another, and the last of the chain delivers its waters by a river into the ocean. The communication was originally begun by a simple overflowing at the lowest part of the margin. This made a torrent, which quickly deepened its bed; and this circumstance increasing its velocity, as we have seen, would extend this deepening backward to the lake, and draw off more of its waters. The work would go on rapidly at first, while earth and small stones only resisted the labours of nature; but these being washed away, and the channel hollowed out to the firm rock on all sides, the operation must go on very slowly, till the immense cascade shall undermine what it cannot break off, and then a new discharge will commence, and a quantity of flat ground will emerge all round the lake. The torrent, in the mean time, makes its way down the country, and digs a canal, which may be called the first sketch of a river, which will deepen and widen its bed continually. The water of several basins united, and running together in a great body, will, according to the principles which we have established, have a much greater velocity, with the same slope, than those of the lakes in the interior parts of the continent; and the sum of them all united in the basin next the sea, after having broken through its natural mound, will make a prodigious torrent, which will dig for itself a bed so much the deeper as it has more slope and a greater body of waters.

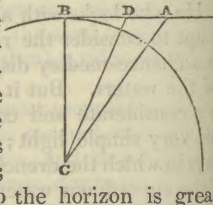
The formation of the first valleys, by cutting open many springs which were formerly concealed under ground, will add to the mass of running waters, and contribute to drain off the waters of these basins. In course of time many of them will disappear, and flat valleys among the mountains and hills are the traces of their former existence.

When nature thus traces out the courses of future rivers, it is to be expected that those streams will most deepen their channels which in their approach to the sea receive into their bed the greatest quantities of rain and spring-waters, and that towards the middle of the continent they will deepen their channels less. In these last situations the natural slope of the fields causes the rain-water, rills, and the little rivulets from the springs, to seek their ways to the rivers. The ground can sink only by the flattening of the hills and high grounds; and this must proceed with extreme slowness, because it is only the gentle though incessant work of the rains and springs. But the rivers, increasing in bulk and strength, and of necessity flowing over every thing, form to themselves capacious beds in a more yielding soil, and dig them even to the level of the ocean.

Beds river form one ed pa

The beds of rivers by no means form themselves in one inclined plane. If we should suppose a canal AB (fig. 14) perfectly straight and horizontal at B, where it joins with the sea, this canal would really be an inclined channel of greater and greater slope as it is farther from B. This is evident; because gravity is directed towards the centre of the earth, and the angle CAB contained between the channel and the plumb-line at A is smaller than the similar angle CDB; and consequently the inclination to the horizon is greater in A than in D. Such a canal, therefore, would make the bed of a river; and some have thought that this was the real form of nature's work; but the supposition is a whim, and it is false. No river has a slope at all approaching to this. It would be eight inches declivity in the mile next the ocean, twenty-four inches in the second mile, forty inches in the third, and so on in the duplicate ratio (for the whole elevation) of the distances from the sea. Such a river would quickly tear up its bed in the mountains (were there any grounds high enough to receive it), and, except its first cascade, would soon acquire a more gentle slope. But the fact is, and it is the result of the imprescriptible laws of nature, that the continued track of a river is a succession of inclined channels, whose slope diminishes by steps as the river approaches to the sea. It is not enough to say that this results from the natural slope of the countries through which it flows, which we observe to increase in declivity as we go to the interior parts of the continent. Were it otherwise, the equilibrium at which nature aims in all her operations would still produce the gradual diminution of the slope of rivers. Without it they could not be in a permanent train.

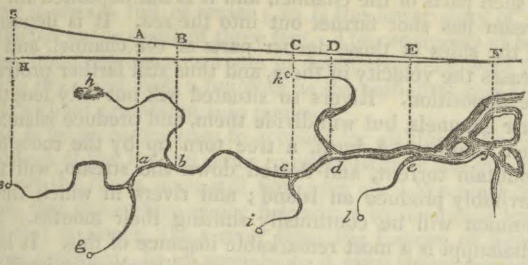
Fig. 14.



How perm cours river tablis

That we may more easily form a notion of the manner in which the permanent course of a river is established, let us suppose a stream or rivulet $s\,a$ (fig. 15) far up the country, makes its way through a soil perfectly uniform to the sea, taking the course $s\,a\,b\,c\,d\,e\,f$, and receiving the *permanent additions* of the stream $g\,a$, $h\,b$, $i\,c$, $k\,d$, $l\,e$, and that its velocity and slope in all its parts are so suited to the tenacity

Fig. 15.



of the soil and magnitude of its section, that neither do its waters during the annual freshes tear up its banks or deepen its bed, nor do they bring down from the high lands materials which they deposit in the channel in times of smaller velocity. Such a river may be said to be in a *permanent state*, to be in *conservation*, or to have *stability*. Let us call this state of a river its REGIMEN, denoting by the word the proper adjustment of the velocity of the stream to the tenacity of the channel. The velocity of its regimen must be the same throughout, because it is this which regulates its action on the bottom, which is the same from its head to the sea. That its bed may have stability, the mean velocity of the current must be constant, notwithstanding the inequality of discharge through its different sections by the brooks which it receives in its course, and notwithstanding the augmentation of its section as it approaches the sea.

On the other hand, it behoved this exact regimen to commence at the mouth of the river, by the working of the whole body of the river, in concert with the waters of the ocean, which always keep within the same limits, and make the ultimate level invariable. This working will begin to dig the bed, giving it as little breadth as possible: for this working consists chiefly in the efforts of falls and rapid streams, which arise of themselves in every channel which has too much slope. The bottom deepens, and the sides remain very steep, till they are undermined and crumbled down; and being then diluted in the water, they are carried down the stream and deposited where the ocean checks its speed. The banks crumble down anew, the valley or hollow forms; but the section, always confined to its bottom, cannot acquire a great breadth, and it retains a good deal of the form of the trapezium formerly mentioned. In this manner does the regimen begin to be established from *f* to *e*.

With respect to the next part *d e*, the discharge or produce is diminished by the want of the brook *l e*. It must take a similar form, but its area will be diminished, in order that its velocity may be the same; and its mean depth *d* being less than in the portion *e f* below, the slope must be greater. Without these conditions we could not have the uniform velocity, which the assumed permanency in an uniform soil naturally supposes. Reasoning after the same manner for all the portions *c d*, *b c*, *a b*, *s a*, we see that the regimen will be successively established in them, and that the slope necessary for this purpose will be greater as we approach the river head. The vertical section or profile of the course of the river *s a b c d e f* will therefore resemble the line SABCDEF which is sketched above, having its different parts variously inclined to the horizontal line HF.

Such is the process of nature to be observed in every river on the surface of the globe. It long appeared a kind of puzzle to the theorists; and it was this observation of the increasing, or at least this continued velocity with smaller slope, as the rivers increased by the addition of their tributary streams, which caused Guglielmini to have recourse to his new principle, the energy of deep waters. We have now seen in what this energy consists. It is only a greater quantity of motion remaining in the middle of a great stream of water after a quantity has been retarded by the sides and bottom; and we see clearly, that since the addition of a new and perhaps an equal stream does not occupy a bed of double surface, the proportion of the retardations to the remaining motion must continually diminish as a river increases by the addition of new streams. If therefore the slope were not diminished, the regimen would be destroyed, and the river would dig up its channel. We have a full confirmation of this in the many works which have been executed on the Po, which runs with rapidity through a rich and yielding soil. About the year 1600 the waters of the Panaro, a very considerable river, were added to the Po Grande; and although it brings along with it in its freshes a vast quantity of sand and mud, it has greatly deepened the whole Tronco di Venezia from the confluence to the sea. This point was clearly ascertained by Manfredi about the year 1720, when the inhabitants of the valleys adjacent were alarmed by the project of bringing in the waters of the Rheno, which then ran through the Ferrarese. Their fears were overcome, and the Po Grande continues to deepen its channel every day, with a prodigious advantage to the navigations; and there are several extensive marshes which now drain off by it, after having been for ages under water: and it is to be particularly remarked, that the Rheno is the foulest river in its freshes of any in that country. We insert this remark, because it may be of great practical utility, as pointing out a method of preserving and even improving the depth of rivers or drains in flat countries, which is not obvious, but rather appears improper; but it is strictly conformable to a true theory, and to the operations of nature, which never fails to adjust every thing so as to bring about an equilibrium. Whatever the declivity of the country may have been originally, the regimen begins to be settled at the mouths of the rivers, and the slopes are diminished in succession as we recede from the coast. The original slopes inland may have been much greater; but they will (when busy nature has completed her work) be left somewhat, and only so much greater, that the velocity may be the same notwithstanding the diminution of the section and mean depth.

Effects of freshes.

Freshes will disturb this methodical progress relative only to the successive permanent additions; but their effects chiefly accelerate the deepening of the bed, and the diminution of the slope, by augmenting the velocity during their continuance. But when the regimen of the permanent additions is once established, the freshes tend chiefly to widen the bed, without greatly deepening it: for the aquatic plants, which have been growing and thriving during the peaceable state of the river, are now laid along, but not swept away, by the freshes, and protect the bottom from their attacks; and the stones and gravel, which must have been left bare in a course of years, working on the soil, will also collect in the bottom, and greatly augment its power of resistance; and even if the floods should have deepened the bottom some small matter, some mud will be deposited as the velocity of the freshes diminishes, and this will remain till the next flood.

We have supposed the soil uniform throughout the whole course; this seldom happens; therefore the circumstances which insure permaneney, or the regimen of a river, may be very different in its different parts and in different rivers. We may say in general, that the farther that the regimen has advanced up the stream in any river, the more slowly will it convey its waters to the sea.

There are some general circumstances in the motion of rivers which it will be proper to take notice of just now, that they may not interrupt our more minute examination of their mechanism; and their explanations will then occur of themselves as corollaries of the propositions which we shall endeavour to demonstrate.

In a valley of small width the river always occupies the lowest part of it; and it is observed, that this is seldom in the middle of the valley, and is nearest to that side on which the slope from the higher grounds is steepest, and this with-

In narrow valleys rivers adhere to the steepest hills.

out regard to the line of its course. The river generally adheres to the steepest hills, whether they advance into the plain or retire from it. This general feature may be observed over the whole globe. It is divided into compartments by great ranges of mountains; and it may be observed, that the great rivers hold their course not very far from them, and that their chief feeders come from the other side. In every compartment there is a swell of the low country at a distance from the bounding ridge of mountains; and on the summit of this swell the principal feeders of the great river have their sources.

The name *valley* is given with less propriety to these immense regions, and is more applicable to tracts of champaign land which the eye can take in at one view. Even here we may observe a resemblance. It is not always in the very lowest part of this valley that the river has its bed: although the waters of the river flow in a channel below its immediate banks, these banks are frequently higher than the grounds at the foot of the hills. This is very distinctly seen in Lower Egypt, by means of the canals which are carried backward from the Nile for accelerating its fertilizing inundations. When the calishes are opened to admit the waters, it is always observed that the districts most remote are the first covered, and it is several days before the immediately adjoining fields partake of the blessing. This is a consequence of that general opinion of nature by which the valleys are formed. The river in its floods is loaded with mud, which it retains as long as it rolls rapidly along its limited bed, tumbling its waters over and over, and taking up in every spot as much as it deposits: but as soon as it overflows its banks, the very enlargement of its section diminishes the velocity of the water; and it may be observed still running in the track of its bed with great velocity, while the waters on each side are stagnant at a very small distance: therefore the water, on getting over the banks, must deposit the heaviest, the firmest, and even the greatest part of its burden, and must become gradually clearer as it approaches the hills. Thus a gentle slope is given to the valley in a direction which is the reverse of what one would expect. It is, however, almost always the case in wide valleys, especially if the great river comes through a soft country. The banks of the brooks and ditches are observed to be deeper as they approach the river, and the merely superficial drains run backwards from it.

The bed of rivers is enlarged near the sea,

We have already observed that the enlargement of the bed of a river, in its approach to the sea, is not in proportion to the increase of its waters. This would be the case even if the velocity continued the same; and, therefore, since the velocity increases in consequence of the greater energy of a large body of water, which we now understand distinctly, a still smaller bed is sufficient for conveying all the water to the sea.

the water being checked by the tides of the ocean.

This general law is broken, however, in the immediate neighbourhood of the sea; because in this situation the velocity of the water is checked by the passing flood-tides of the ocean. As the whole waters must still be discharged, they require a larger bed, and the enlargement will be chiefly in width. The sand and mud are deposited when the motion is retarded. The depth of the mouth of the channel is therefore diminished. It must therefore become wider. If this be done on a coast exposed to the force of a regular tide, which carries the waters of the ocean across the mouth of the river, this regular enlargement of the mouth will be the only consequence, and it will generally widen till it washes the foot of the adjoining hills; but if there be no tide in the sea, or a tide which does not set across the mouth of the river, the sands must be deposited at the sides of the opening, and become additions to the shore, lengthening the mouth of the channel. In this sheltered situation, every trivial circumstance will cause the river to work more on particular parts of the bottom, and deepen the channel there. This keeps the mud suspended in such parts of the channel, and it is not deposited till the stream has shot farther out into the sea. It is deposited on the sides of those deeper parts of the channel, and increases the velocity in them, and thus still farther protracts the deposition. Rivers so situated will not only lengthen their channels, but will divide them, and produce islands at their mouths. A bush, a tree torn up by the roots by a mountain torrent, and floated down the stream, will thus inevitably produce an island; and rivers in which this is common will be continually shifting their mouths. The Mississippi is a most remarkable instance of this. It has a long course through a rich soil, and disembogues itself into the bay of Mexico, in a place where there is no *passing tide*, as may be seen by comparing the hours of high water in different places. No river that we know carries down its stream such numbers of rooted-up trees; they frequently interrupt the navigation, and render it always dangerous in the night-time. This river is so beset with flats and shifting sands at its mouth, that the most experienced pilots are puzzled; and it has protruded its channel above fifty miles in the short period that we have known it. The discharge of the Danube is very similar: so is that of the Nile, for it is discharged into a still corner of the Mediterranean. It may now be said to have acquired considerable permanency; but much of this is owing to human industry, which strips it as much as possible of its subsideable matter. The Ganges, too, is in a situation pretty similar, and exhibits similar phenomena. The Maragnon might be noticed as an exception; but it is not an exception. It has flowed very far in a level bed, and its waters come pretty clear to Para; but, besides, there is a strong transverse tide, or rather current, at its mouth, setting to the south-east both during flood and ebb. The mouth of the Po is perhaps the most remarkable of any on the surface of this globe, and exhibits appearances extremely singular. Its discharge is into a sequestered corner of the Adriatic. Though there be a more remarkable tide in this gulf than in any part of the Mediterranean, it is still but trifling, and it either sets directly in upon the mouth of the river or retires straight away from it. The river has many mouths, and they shift prodigiously. There has been a general increase of the land very remarkable. The marshes where Venice now stands were in the Augustan age everywhere penetrable by the fishing-boats, and in the fifth century could only bear a few miserable huts; now they are covered with crowds of stately buildings. Ravenna, situated on the southernmost mouth of the Po, was, in the Augustan age, at the extremity of a swamp, and the road to it was along the top of an artificial mound, made by Augustus at an immense expense. It was, however, a fine city, containing extensive docks, arsenals, and other massy buildings, being the great military port of the empire, where Augustus laid up his great ships of war. In the Gothic times it became almost the capital of the western empire, and was the seat of government and of luxury. It must therefore be supposed to have every accommodation of opulence, and we cannot doubt of its having paved streets, wharfs, &c.; so that its wealthy inhabitants were at least walking dryfooted from house to house. But now it is an Italian mile from the sea, and surrounded with vineyards and cultivated fields, and is accessible in every direction. All this must have been formed by depositions from the Po, flowing through Lombardy loaded with the spoils of the Alps, which were here arrested by the reeds and bulrushes of the marsh. These things are in common course; but when wells are dug, we come to the pavements of the ancient city, and these pavements are all on one exact level, and they *are eight feet below the surface of the sea at low water.* This cannot be ascribed to the subsiding of the ancient city. This would be irregular, and greatest among the heavy

The

buildings. The tomb of Theodoric remains, and the pavement round it is on a level with all the others. The lower story is always full of water; so is the lower story of the cathedral to the depth of three feet. The ornaments of both these buildings leave no room to doubt that they were formerly dry; and such a building as the cathedral could not sink without crumbling into pieces.

It is by no means easy to account for all this. The depositions of the Po and other rivers must raise the ground; and yet the rivers must still flow over all. We must conclude that the surface of the Adriatic is by no means level, and that it slopes like a river from the Lagoon of Venice to the eastward. In all probability it even slopes considerably outwards from the shore. This will not hinder the alternations of ebb and flow tide, as will be shown in its proper place. The whole shores of this gulf exhibit most uncommon appearances.

Ri s are con x ath rt the ream, and e cau of it.

The last general observation which we shall make in this place is, that the surface of a river is not flat, considered athwart the stream, but convex; this is owing to its motion. Suppose a canal of stagnant water; its surface would be a perfect level. But suppose it possible, by any means, to give the middle waters a motion in the direction of its length, they must drag along with them the waters immediately contiguous. These will move less swiftly, and will in like manner drag the waters without them; and thus the water at the sides being abstracted, the depth must be less, and the general surface must be convex across. The fact in a running stream is similar to this; the side waters are withheld by the sides, and every filament is moving more slowly than the one next it towards the middle of the river, but faster than the adjoining filament on the land side. This alone must produce a convexity of surface. But besides this, it is demonstrable that the pressure of a running stream is diminished by its motion, and the diminution is proportional to the height which would produce the velocity with which it is gliding past the adjoining filament. This convexity must in all cases be very small. Few rivers have the velocity nearly equal to eight feet per second, and this requires a height of one foot only. An author quoted by M. Buffon says, that he has observed on the river Aveiron an elevation of three feet in the middle during floods; but we suspect some error in the observation.

§ 4. *Of the Windings of Rivers.*

Win g cours f rivers ow forme

Rivers are seldom straight in their course. Formed by the hand of nature, they are accommodated to every change of circumstance. They wind around what they cannot get over, and work their way to either side according as the resistance of the opposite bank makes a straight course more difficult; and this seemingly fortuitous rambling distributes them more uniformly over the surface of a country, and makes them everywhere more at hand, to receive the numberless rills and rivulets which collect the waters of our springs and the superfluities of our showers, and to comfort our habitations with the many advantages which cultivation and society can derive from their presence. In their feeble beginnings the smallest inequality of slope or consistency is enough to turn them aside and make them ramble through every field, giving drink to our herds and fertility to our soil. The more we follow nature into the minutiæ of her operations, the more must we admire the inexhaustible fertility of her resources, and the simplicity of the means by which she produces the most important and beneficial effects. By thus twisting the course of our rivers into ten thousand shapes, she keeps them long amidst our fields, and thus compensates for the declivity of the surface, which would otherwise tumble them with great rapidity into the ocean, loaded with the best and richest of our soil. Without this, the showers of heaven would have little influence in supplying the waste of incessant evaporation. But as things are, the rains are kept slowly trickling along the sloping sides of our hills and steeps, winding round every clod, nay, every plant, which lengthens their course, diminishes their slope, checks their speed, and thus prevents them from quickly brushing off from every part of the surface the lightest and best of the soil. The fattest of our holm lands would be too steep, and the rivers would shoot along through our finest meadows, hurrying every thing away with them, and would be unfit for the purposes of inland conveyance, if the inequalities of soil did not make them change this headlong course for the more beautiful meanders which we observe in the course of the small rivers winding through our meadows. Those rivers are in general the straightest in their course which are the most rapid, and which roll along the greatest bodies of water: such are the Rhone, the Po, the Danube. The smaller rivers continue more devious in their progress, till they approach the sea, and have gathered strength from all their tributary streams.

What nature left for man to perform.

Every thing aims at an equilibrium, and this directs even the rambling of rivers. It is of importance to understand the relation between the force of a river and the resistance which the soil opposes to those deviations from a rectilineal course; for it may frequently happen that the general procedure of nature may be inconsistent with our local purposes. Man was set down on this globe, and the task of cultivating it was given him by nature, and his chief enjoyment seems to be to struggle with the elements. He must not find things to his mind, but he must mould them to his own fancy. Yet even this seeming anomaly is one of nature's most beneficent laws; and his exertions must still be made in conformity with the general train of the operations of mechanical nature; and when we have any work to undertake relative to the course of rivers, we must be careful not to thwart their general rules, otherwise we shall sooner or later be punished for their infraction. Things will be brought back to their former state, if our operations are inconsistent with that equilibrium which is constantly aimed at, or some new state of things which is equivalent will soon be induced. If a well-regulated river has been improperly deepened in some place to answer some particular purpose of our own, or if its breadth has been improperly augmented, we shall soon see a deposition of mud or sand choke up our fancied improvements; because, as we have enlarged the section without increasing the slope or the supply, the velocity must diminish, and floating matters must be deposited.

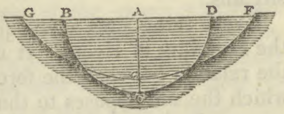
It is true, we frequently see permanent channels where the forms are extremely different from that which the waters would dig for themselves in an uniform soil, and which approaches a good deal to the trapezium described formerly. We see a greater breadth frequently compensate for a want of depth; but all such deviations are a sort of constraint, or rather are indications of inequality of soil. Such irregular forms are the works of nature; and if they are permanent, the equilibrium is obtained. Commonly the bottom is harder than the sides, consisting of the coarsest of the sand and of gravel; and therefore the necessary section can be obtained only by increasing the width. We are accustomed to attend chiefly to the appearances which prognosticate mischief, and we interpret the appearances of a permanent bed in the same way, and frequently form very false judgments. When we see one bank low and flat, and the other high and abrupt, we suppose that the waters are passing along the first in peace, and with a gentle stream, but that they are rapid on the other side, and are tearing away the bank; but it is just the contrary. The bed being permanent, things are in equilibrio, and each bank is of a form just competent to that equilibrium. If the soil on both sides be uniform, the stream is most rapid on that side where the bank is low and flat, for in no other form would it withstand the action of the stream; and it has been worn away till its flatness compensates for the greater force of the stream. The stream on the other side must be more gentle, otherwise the bank could not remain abrupt. In short, in a state of permanency, the velocity of the stream and form of the bank are just suited to each other. It is quite otherwise before the river has acquired its proper regimen.

Necessity of attending to nature in regulating the course of rivers.

A careful consideration therefore of the general features of rivers which have settled their regimen, is of use for informing us concerning their internal motions, and directing us to the most effectual methods of regulating their course.

We have already said that perpendicular brims are inconsistent with stability. A semicircular section is the form which would produce the quickest train of a river whose expense and slope are given; but the banks at B and D (fig. 16) would crumble in, and lie at the bottom, where their horizontal surface would secure them from farther change. The bed will acquire the form G*c*F, of equal section, but greater width, and with brims less shelving. The proportion of the velocities at A and *c* may be the same with that of the velocities at A and C; but the velocity at G and F will be less than it was formerly at B, C, or D; and the velocity in any intermediate point E, being somewhat between those at F and *c*, must be less than it was in any intermediate point of the semicircular bed. The velocities will therefore decrease along the border from *c* towards G and F, and the steepness of the border will augment at the same time, till, in every point of the new border G*c*F, these two circumstances will be so adjusted that the necessary equilibrium is established.

Fig. 16.



The same thing must happen in our trapezium. The slope of the brims may be exact, and will be retained; it will, however, be too great anywhere below, where the velocity is greater, and the sides will be worn away till the banks are undermined and crumble down, and the river will maintain its section by increasing its width. In short, no border made up of straight lines is consistent with that gradation of velocity which will take place whenever we depart from a semicircular form. And we accordingly see, that in all natural channels the section has a curvilineal border, with the slope increasing gradually from the bottom to the brim.

These observations will enable us to understand how nature operates when the inequality of surface or of tenacity obliges the current to change its direction, and the river forms an elbow.

Conditions necessary for a permanent regimen.

Supposing always that the discharge continues the same, and that the mean velocity is either preserved or restored, the following conditions are necessary for a permanent regimen.

1. The depth of water must be greater in the elbow than anywhere else.

2. The main stream, after having struck the concave bank, must be reflected in an equal angle, and must then be in the direction of the next reach of the river.

3. The angle of incidence must be proportioned to the tenacity of the soil.

4. There must be in the elbow an increase of slope, or of head of water, capable of overcoming the resistance occasioned by the elbow.

Reasonableness of these conditions.

The reasonableness, at least, of these conditions will appear from the following considerations.

1. It is certain that force is expended in producing this change of direction in a channel which by supposition diminishes the current. The diminution arising from any cause which can be compared with friction must be greater when the stream is directed against one of the banks. It may be very difficult to state the proportion, and it would occupy too much of our time to attempt it; but it is sufficient that we be convinced that the retardation is greater in this case. We see no cause to increase the mean velocity in the elbow, and we must therefore conclude that it is diminished. But we are supposing that the discharge continues the same; the section must therefore augment, or the channel increase its transverse dimensions. The only question is, In what manner it does this, and what change of form does it affect, and what form is competent to the final equilibrium and the consequent permanency of the bed? Here there is much room for conjecture. M. de Buat reasons as follows: If we suppose that the points B and C (fig. 17) continue on a level, and that the points H and I at the beginning of the next reach are also on a level, it is an inevitable consequence that the slope along CMI must be greater than along BEH, because the depression of H below B is equal to that of I below C, and BEH is longer than CMI. Therefore the velocity along the convex bank CMI must be greater than along BEH. There may even be a stagnation and an eddy in the contrary direction along the concave bank. Therefore, if the form of the section were the same as up the stream, the sides could not stand on the convex bank. When therefore the section has attained a permanent form, and the banks are again in equilibrio with the action of the current, the convex bank must be much flatter than the concave. If the water is really still on the concave bank, that bank will be absolutely perpendicular, nay, may overhang. Accordingly, this state of things is matter of daily observation, and justifies our reasoning, and entitles us to say, that this is the nature of the internal motion of the filaments which we cannot distinctly observe. The water moves most rapidly along the convex bank, and the thread of the stream is nearest to this side. Reasoning in this way, the section, which we may suppose to have been originally of the form M*b* *a*E (fig 18), assumes the shape MBAE.

Fig. 17.

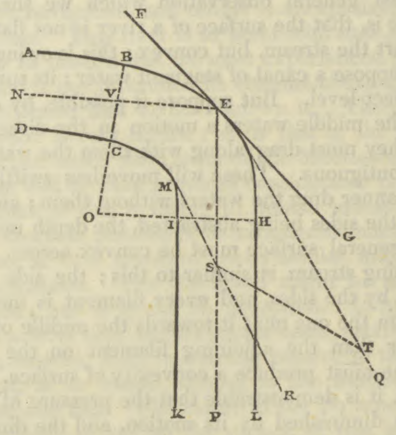


Fig. 18.

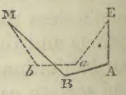


2. Without presuming to know the mechanism of the internal motions of fluids, we know that superficial waves are reflected precisely as if they were elastic bodies, making the angles of incidence and reflection equal. In as far, therefore, as the superficial wave is concerned in the operation, M. de Buat's second position is just. The permanency of the next reach requires that its axis shall be in the direction of the line EP (fig. 17), which makes the angle GEP = FEN. If the next reach has the direction EQ, MR, the wave reflected in the line ES will work on the bank at S, and will be

reflected in the line ST, and work again on the opposite bank at T. We know that the effect of the superficial motion is great, and that it is the principal agent in destroying the banks of canals. So far therefore M. de Buat is right. We cannot say with any precision or confidence how the actions of the under filaments are modified; but we know no reason for not extending to the under filaments what appears so probable with respect to the surface-water.

3. The third position is no less evident. We do not know the mode of action of the water on the bank; but our general notions on this subject, confirmed by common experience, tell us that the more obliquely a stream of water beats on any bank, the less it tends to undermine it or wash it away. A stiff and cohesive soil therefore will suffer no more from being almost perpendicularly buffeted by a stream than a friable sand would suffer from water gliding along its face. M. de Buat thinks, from experience, that a clay bank is not sensibly affected till the angle FEB is about thirty-six degrees.

4. Since there are causes of retardation, and we still suppose that the discharge is kept up, and that the mean velocity, which had been diminished by the enlargement of the section, is again restored, we must grant that there is provided, in the mechanism of these motions, an accelerating force adequate to this effect. There can be no accelerating force in an open stream but the superficial slope. In the present case it is undoubtedly so; because by the deepening of the bottom where there is an elbow in the stream, we have of necessity a counter slope. Now, all this head of water, which must produce the augmentation of velocity in that part of the stream which ranges round the convex bank, will arise from the check which the water gets from the concave bank. This occasions a gorge or swell up the stream, enlarges a little the section at BVC; and this, by the principle of uniform motion, will augment all the velocities, deepen the channel, and put every thing again into its train as soon as the water gets into the next reach. The water at the bottom of this basin has very little motion, but it defends the bottom by this very circumstance.

Rema on the condit s, and th reason f them.

Such are the notions which M. de Buat entertains of this part of the mechanism of running waters. We cannot say that they are very satisfactory, and they are very opposite to the opinions commonly entertained on the subject. Most persons think that the motion is most rapid and turbulent on the side of the concave bank, and that it is owing to this that the bank is worn away till it has become perpendicular, and that the opposite bank is flat, because it has not been gnawed away in this manner. With respect to this general view of the matter, these persons may be in the right; and when a stream is turned into a crooked and yielding channel for the first time, this is its manner of action. But M. de Buat's aim is to investigate the circumstances which obtain in the case of a regimen; and in this view he is undoubtedly right as to the facts, though his mode of accounting for these facts may be erroneous. And as this is the only useful view to be taken of the subject, it ought chiefly to be attended to in all our attempts to procure stability to the bed of a river, without the expensive helps of masonry, &c. If we attempt to secure permanency by deepening on the inside of the elbow, our bank will undoubtedly crumble down, diminish the passage, and occasion a more violent action on the hollow bank. The most effectual mean of security is to enlarge the section; and if we do this on the inside bank, we must do it by widening the stream very much, that we may give a very sloping bank. Our attention is commonly drawn to it when the hollow bank is giving way, and with a view to stop the ravages of the stream. Things are not now in a state of permanency, but nature is working in her own way to bring it about. This may not suit *our* purpose, and we must thwart her. The phenomena which we then observe are frequently very unlike to those described in the preceding paragraphs. We see a violent tumbling motion in the stream towards the hollow bank. We see an evident accumulation of water on that side, and the point B is frequently higher than C. This regorging of the water extends to some distance, and is of itself a cause of greater velocity, and contributes, like a head of stagnant water, to force the stream through the bend, and to deepen the bottom. This is clearly the case when the velocity is excessive, and the hollow bank able to abide the shock. In this situation the water thus heaped up escapes where it best can; and as the water obstructed by an obstacle put in its way escapes by the sides, and there has its velocity increased, so here the water gorged up against the hollow bank swells over towards the opposite side, and passes round the convex bank with an increased velocity. It depends much on the adjustment between the velocity and consequent accumulation, and the breadth of the stream and the angle of the elbow, whether this augmentation of velocity shall reach the convex bank; and we sometimes see the motion very languid in that place, and even depositions of mud and sand are made there. The whole phenomena are too complicated to be accurately described in general terms, even in the case of perfect regimen: for this regimen is relative to the consistence of the channel; and when this is very great, the motions may be most violent in every quarter. But the preceding observations are of importance, because they relate to ordinary cases and to ordinary channels.

It is evident, from M. de Buat's second position, that the proper form of an elbow depends on the breadth of the stream as well as on the radius of curvature, and that every angle of elbow will require a certain proportion between the width of the river and the radius of the sweep. M. de Buat gives rules and formulæ for all these purposes, and shows that in one sweep there may be more than one reflection or rebound. It is needless to enlarge on this matter of mere geometrical discussion. It is with the view of enabling the engineer to trace the windings of a river in such a manner that there shall be no rebounds which shall direct the stream against the sides, but preserve it always in the axis of every reach. This is of consequence, even when the bends of the river are to be secured by masonry or piling; for we have seen the necessity of increasing the section, and the tendency which the waters have to deepen the channel on that side where the rebound is made. This tends to undermine our defences, and obliges us to give them deeper and more solid foundations in such places. But any person accustomed to the use of the scale and compasses will form to himself rules of practice equally sure and more expeditious than M. de Buat's formulæ.

Resistance caused by an elbow, and mode of overcoming it.

We proceed, therefore, to what is more to our purpose, the consideration of the resistance caused by an elbow, and the methods of providing a force capable of overcoming it. We have already taken notice of the salutary consequences arising from the rambling course of rivers, inasmuch as it more effectually spreads them over the face of a country. It is no less beneficial by diminishing their velocity. This it does both by lengthening their course, which diminishes the declivity, and by the very resistance which they meet with at every bend. We derive the chief advantages from our rivers when they no longer shoot their way from precipice to precipice loaded with mud and sand, but peaceably roll along their clear waters, purified during their gentler course, and offer themselves for all the purposes of pasturage, agriculture, and navigation. The more a river winds its way round the foot of the hills, the more is the resistance of its bed multiplied; the more obstacles it meets with in its way from its source to the sea, the more moderate is its velocity; and instead of tearing up the very bowels of the earth, and digging for itself a deep trough, along which it sweeps rocks and rooted-up trees, it flows with majestic

Theory.

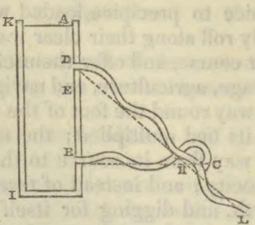
pace even with the surface of our cultivated grounds, which it embellishes and fertilizes.

We may with safety proceed on the supposition, that the force necessary for overcoming the resistance arising from a rebound is as the square of the velocity; and it is reasonable to suppose it proportional to the square of the sine of the angle of incidence, and this for the reasons given for adopting this measure of the general *Resistance of Fluids*. It cannot, however, claim a greater confidence here than in that application; and it has been shown in that article with what uncertainty and limitations it must be received. We leave it to our readers to adopt either this or the simple ratio of the sines, and shall abide by the duplicate ratio with M. de Buat, because it appears by his experiments that this law is very exactly observed in tubes in inclinations not exceeding 40°; whereas it is in these small angles that the application to the general resistance of fluids is most in fault. But the correction is very simple if this value shall be found erroneous. There can be no doubt that the force necessary for overcoming the resistance will increase as the number of rebounds. Therefore we may express the resistance, in general, by the formula $r = \frac{n V^2 \sin.^2 I}{m}$; where r is the resistance, V the mean velocity of the stream, sin. I the sine of the angle of incidence, n the number of equal rebounds (that is, having equal angles of incidence), and m is a number to be determined by experiment. M. de Buat made many experiments on the resistance occasioned by the bendings of pipes, none of which differed from the result of the above formula above one part in twelve; and he concludes, that the resistance to one bend may be estimated at $\frac{V^2 \sin.^2 I}{3000}$. The experiment was in this form. A pipe of one inch diameter, and ten feet long, was formed with ten rebounds of 36° each. A head of water was applied to it, which gave the water a velocity of six feet per second. Another pipe of the same diameter and length, but without any bendings, was subjected to a pressure of a head of water, which was increased till the velocity of efflux was also six feet per second. The additional head of water was $5\frac{9}{10}$ inches. Another of the same diameter and length, having one bend of 24° 34′, and running eighty-five inches per second, was compared with a straight pipe having the same velocity, and the difference of the heads of water was $\frac{37}{100}$ of an inch. A computation from these two experiments will give the above result, or, in English measure, $r = \frac{V^2 \sin.^2 I}{3200}$ very nearly. It is probable that this measure of the resistance is too great; for the pipe was of uniform diameter even in the bends: whereas, in a river properly formed, where the regimen is exact, the capacity of the section of the bend is increased.

Theory applied to inclined tubes and open streams.

The application of this theory to inclined tubes and to open streams is very obvious, and very legitimate and safe. Let AB (fig. 19) be the whole height of the reservoir ABIK, and BC the horizontal length of a pipe, containing any number of rebounds, equal or unequal, but all regular, that is, constructed according to the conditions formerly mentioned. The whole head of water should be conceived as performing, or as divided into portions which perform, three different offices. One portion, $AD = \frac{V^2}{509}$, impels the water into the entry of the pipe with the velocity with which it really moves in it; another portion EB is in equilibrio with the resistances arising from the mere length of the pipe expanded into a straight line; and the third portion DE serves to overcome the resistance of the bends. If, therefore, we draw the horizontal line BC, and, taking the pipe BC out of its place, put it in the position DH, with its mouth C in H, so that DH is equal to BC, the water will have the same velocity in it that it had before. For greater simplicity of argument, we may suppose that when the pipe was inserted at B, its bends lay all in a horizontal plane, and that when it is inserted at D, the plane in which all its bends lie slopes only in the direction DH, and is perpendicular to the plane of the figure. We repeat it, the water will have the same velocity in the pipes BC and DH, and the resistances will be overcome. If we now prolong the pipe DH towards L to any distance, repeating continually the same bendings in a series of lengths, each equal to DH, the motion will be continued with the velocity corresponding to the pressure of the column AD; because the declivity of the pipe is augmented in each length equal to DH, by a quantity precisely sufficient for overcoming all the resistances in that length; and the true slope in these cases is BE + ED, divided by the expanded length of the pipe BC or DH.

Fig. 19.



The analogy which we were enabled to establish between the uniform motion or the train of pipes and of open streams, entitles us now to say, that when a river has bendings, which are regularly repeated at equal intervals, its slope is compounded of the slope which is necessary for overcoming the resistance of a straight channel of its whole expanded length, agreeably to the formula for uniform motion, and of the slope which is necessary for overcoming the resistance arising from its bending alone.

Thus, let there be a river which, in the expanded course of 6000 fathoms, has 10 elbows, each of which has 30° of rebound; and let its mean velocity be 20 inches in a second. If we should learn its whole slope in this 6000 fathoms, we must first find (by the formula of uniform motion) the slope s which will produce the velocity of 20 inches in a straight river of this length, section, and mean depth. Suppose this to be $\frac{1}{21600}$, or 20 inches, in this whole length. We must then find by the formula $\frac{n V^2 \sin.^2 I}{3200}$ the slope necessary for overcoming the resistance of ten rebounds of 30° each. This we shall find to be $6\frac{2}{3}$ inches in the 6000 fathoms. Therefore the river must have a slope of $26\frac{2}{3}$ inches in 6000 fathoms, or $\frac{1}{16200}$; and this slope will produce the same velocity which 20 inches, or $\frac{1}{21600}$, would do in a straight-running river of the same length.

PART II.—PRACTICAL INFERENCES.

Approxi-mation trial an correcti recom-mende practic engine

Having thus established a theory of a most important part of hydraulics, which may be confided in as a just representation of nature's procedure, we shall apply it to the examination of the chief results of every thing which art has contrived for limiting the operations of nature, or modifying them so as to suit our particular views. Trusting to the detail which we have given of the connecting principles, and the chief circumstances which co-operate in producing the ostensible effect; and supposing that such of our readers as are interested in this subject will not think it too much trouble to make the applications in the same detail; we shall content ourselves with merely pointing out the steps of the process, and showing their foundation in the theory itself; and frequently, in place of the direct analysis which the theory enables us to employ for the solution of the problems, we shall recommend a process of approximation by trial and correction, sufficiently accurate, and more within the reach of practical engineers.

Practical Inferences.

We are naturally led to consider in order the following articles.

1. The effects of permanent additions of every kind to the waters of a river, and the most effectual methods of preventing or removing inundations.

2. The effects of weirs, bars, sluices, and keeps of every kind, for raising the surface of a river; and the similar effects of bridges, piers, and every thing which contracts the section of the stream.

3. The nature of canals; how they differ from rivers in respect of origin, discharge, and regimen, and what conditions are necessary for their most perfect construction.

4. Canals for draining land, and drafts or canals of derivation from the main stream. The principles of their construction, so that they may suit their intended purposes; and the change which they produce on the main stream, both above and below the point of derivation.

Of the Effects of Permanent Additions to the Waters of a River.

Problems and examples of the effects of permanent additions to the waters of a river.

From what has already been said, it appears that to every kind of soil or bed there corresponds a certain velocity of current, too small to hurt it by digging it up, and too great to allow the deposition of the materials which it is carrying along. Supposing this known for any particular situation, and the quantity of water which the channel must of necessity discharge, we may wish to learn the smallest slope which must be given to this stream, that the waters may run with the required velocity. This suggests,

PROB. I.[1] Given the discharge D of a river, and V its velocity of regimen: required the smallest slope s, and the dimensions of its bed.

Since the slope must be the smallest possible, the bed must have the form which will give the greatest mean depth d, and should therefore be the trapezium formerly described; and its area and perimeter are the same with those of a rectangle whose breadth is twice its height h. These circumstances gives us the equation $\frac{D}{V} = 2h^2$. For the area of the section is twice the square of the height, and the discharge is the product of this area and the velocity. Therefore $\sqrt{\frac{D}{2V}} = h$ and $\sqrt{\frac{2D}{V}} =$ the breadth b.

The formula of uniform motion gives $\sqrt{s} - L\sqrt{s + 1{\cdot}6} = \frac{297\,(\sqrt{d} - 0{\cdot}1)}{V + 0{\cdot}3\,(\sqrt{d} - 0{\cdot}1)}$. Instead of $\sqrt{d} - 0{\cdot}1$, put its equal $\sqrt{\frac{h}{2}} - 0{\cdot}1$, and every thing being known in the second side of this equation, we easily get the value of s by a few trials after the following manner: Suppose that the second side is equal to any number, such as 9. First suppose that $\sqrt{s}$ is $= 9$, whence $s = 81$. Then the hyperbolic logarithm of $\sqrt{81 + 1{\cdot}6}$ or $\sqrt{82{\cdot}6}$ is 2·21. Therefore we have $\sqrt{s} - L\sqrt{s + 1{\cdot}6} = 9 - 2{\cdot}21 = 6{\cdot}79$; whereas it should have been $= 9$. Therefore say $6{\cdot}79 : 9 = 9 : 11{\cdot}9$ nearly. Now suppose that $\sqrt{s}$ is $= 11{\cdot}9$, whence $s = 141{\cdot}6$. Then $L\sqrt{141{\cdot}6 + 1{\cdot}6} = L\sqrt{143{\cdot}2} = 2{\cdot}482$ nearly, and $11{\cdot}9 - 2{\cdot}482 = 9{\cdot}408$, whereas it should be 9. Now we find that changing the value of $\sqrt{s}$ from 9 to 11·9 has changed the answer from 6·79 to 9·408, or a change of 2·9 in our assumption has made a change of 2·618 in the answer, and has left an error of 0·408. Therefore say $2{\cdot}618 : 0{\cdot}408 = 2{\cdot}9 : 0{\cdot}452$. Then taking 0·452 from 11·9, we have, for our next assumption or value of $\sqrt{s}$, 11·448, whence $s = 131{\cdot}1$. Now $131{\cdot}1 + 1{\cdot}6 = 132{\cdot}7$, and $L\sqrt{132{\cdot}7} = 2{\cdot}444$ nearly, and $11{\cdot}448 - 2{\cdot}444 = 9{\cdot}004$ in place of 9, whence it is inferred that this last value of $\sqrt{s} = 11{\cdot}448$ is sufficiently exact. This may serve as a specimen of the trials by which we may avoid an intricate analysis.

Practical Inferences.

PROB. II. Given the discharge D, the slope s, and the velocity V, of permanent regimen, to find the dimensions of the bed.

Let x be the width and y the depth of the channel, and S the area of the section. This must be $= \frac{D}{V}$, which is therefore $= xy$. The denominator s being given, we may make $\sqrt{s} - L\sqrt{s + 1{\cdot}6} = \sqrt{B}$, and the formula of mean velocity will give $V = \frac{297\,(\sqrt{d} - 0{\cdot}1)}{\sqrt{B}} - 0{\cdot}3\,(\sqrt{d} - 0{\cdot}1)$, which we may express thus: $V = (\sqrt{d} - 0{\cdot}1)\left(\frac{297}{\sqrt{B}} - 0{\cdot}3\right)$, which gives $\frac{V}{\frac{297}{\sqrt{B}} - 0{\cdot}3} = (\sqrt{d} - 0{\cdot}1)$; and, finally, $\frac{V}{\frac{297}{\sqrt{B}} - 0{\cdot}3} + 0{\cdot}1 = \sqrt{d}$.

Having thus obtained what we call the mean depth, we may suppose the section rectangular. This gives $d = \frac{xy}{x + 2y}$. Thus we have two equations, $S = xy$ and $d = \frac{xy}{x + 2y}$. From which we obtain $x = \sqrt{\left(\frac{S}{2d}\right)^2 - 2S} + \frac{S}{2d}$. And having the breadth x and area S, we have $y = \frac{S}{x}$. And then we may change this for the trapezium often mentioned.

These are the chief problems on this part of the subject, and they enable us to adjust the slope and channel of a river which receives any number of successive permanent additions by the influx of other streams. This last informs us of the rise which a new supply will produce, because the additional supply will require additional dimensions of the channel; and as this is not supposed to increase in breadth, the addition will be in depth. The question may be proposed in the following problem.

PROB. III. Given the slope s, the depth and the base of a rectangular bed (or a trapezium), and consequently the discharge D, to find how much the section will rise if the discharge be augmented by a given quantity.

Let h be the height after the augmentation, and w the width for the rectangular bed. We have in any uniform current $\sqrt{d} = \frac{V}{\frac{297}{\sqrt{B}} - 0{\cdot}3} + 0{\cdot}1$. Raising this to a square, and putting for d and V their values $\frac{wh}{w + 2h}$ and $\frac{D}{wh}$, and making $\frac{297}{\sqrt{B}} - 0{\cdot}3 = K$, the equation becomes $\frac{wh}{w + 2h} = \left(\frac{D}{whK} + 0{\cdot}1\right)^2$. Raising the second member to a square, and reducing, we obtain a cubic equation, to be solved in the usual manner.

But the solution would be extremely complicated. We may obtain a very expeditious and exact approximation from this consideration, that a small change in one of the dimensions of the section will produce a much greater change in the section and the discharge than in the mean

---

[1] In these problems and examples the measures are expressed in French inches. For English inches the co-efficient 307 must be used in place of 297.

Practical Inferences.

depth d. Having therefore augmented the unknown dimension, which is here the height, make use of this to form a new mean depth, and then the new equation $\sqrt{d} = \frac{D}{w\,h\left(\frac{297}{\sqrt{B}} - 0{\cdot}3\right)} + 0{\cdot}1$ will give us another value of h, which will rarely exceed the truth by $\frac{1}{10}$. This serves (by the same process) for finding another, which will commonly be sufficiently exact. We shall illustrate this by an example.

Let there be a river whose channel is a rectangle 150 feet wide and six feet deep, and which discharges 1500 cubic feet of water per second, having a velocity of twenty inches, and slope of $\frac{1}{12000}$, or about $\frac{7}{12}$ of an inch in 100 fathoms. How much will it rise if it receives an addition which triples its discharge? and what will be its velocity?

If the velocity remained the same, its depth would be tripled; but we know by the general formula that its velocity will be greatly increased, and therefore its depth will not be tripled. Suppose it to be doubled, and to become twelve feet. This will give $d = 10{\cdot}34483$, or 124·138 inches; then the equation $\sqrt{d} - 0{\cdot}1 = \frac{D}{w\,h\left(\frac{297}{\sqrt{B}} - 0{\cdot}3\right)}$, or $h = \frac{D}{w\,(\sqrt{d} - 0{\cdot}1)\left(\frac{297}{\sqrt{B}} - 0{\cdot}3\right)}$, and in which we have $\sqrt{B} = 107{\cdot}8$, $D = 4500 \times 1728 = 7776000$ cubic inches, $w = 1800$ inches, $\sqrt{d} - 0{\cdot}1 = 11{\cdot}0417$, will give $h = 159{\cdot}33$ inches or 13·276 feet; whereas it should have been 12. This shows that our calculated value of d was too small. Let us therefore increase the depth by 0·9, or make it 12·9, and repeat the calculation. This will give us $\sqrt{d} - 0{\cdot}1 = 11{\cdot}3927$, and $h = 12{\cdot}867$, instead of 13·276. Therefore, augmenting our data, 0·9 changes our answer 0·409. If we suppose these small changes to retain their proportions, we may conclude that if 12 be augmented by the quantity $x \times 0{\cdot}9$, the quantity 13·276 will diminish by the quantity $x \times 0{\cdot}409$. Therefore, that the estimated value of h may agree with the one which results from the calculation, we must have $12 + x \times 0{\cdot}9 = 13{\cdot}276 - x \times 0{\cdot}409$. This will give $x = \frac{1{\cdot}276}{1{\cdot}309} = 0{\cdot}9748$; and $x \times 0{\cdot}9 = 0{\cdot}8773$; and $h = 12{\cdot}8773$. If we repeat the calculation with this value of h, we shall find no change.

This value of h gives $d = 131{\cdot}8836$ inches. If we now compute the new velocity by dividing the new discharge 4500 by the new area $150 \times 12{\cdot}8773$, we shall find it to be 27·95 inches, in place of 20, the former velocity.

We might have made a pretty exact first assumption, by recollecting what was formerly observed, that when the breadth is very great in proportion to the depth, the mean depth differs insensibly from the real depth, or rather follows nearly the same proportions, and that the velocities are proportional to the square roots of the depths. Call the first discharge d, the height h, and velocity v, and let D, H, and V, express these things in their augmented state. We have $v = \frac{d}{w\,h}$ and $V = \frac{D}{w\,H}$, and $v : V = \frac{d}{h} : \frac{D}{H}$, and $v^2 : V^2 = \frac{d^2}{h^2} : \frac{D^2}{H^2}$. But by this remark $v^2 : V^2 = h : H$. Therefore $h : H = \frac{d^2}{h^2} : \frac{D^2}{H^2}$, and $\frac{hD^2}{H^2} = \frac{Hd^2}{h^2}$, and $h^3D^2 = H^3d^2$, and $d^2 : D^2 = h^3 : H^3$ (a useful theorem), and $H^3 = \frac{h^3D^2}{d^2}$, and $H = \sqrt[3]{\frac{h^3D^2}{d^2}} = 12{\cdot}48$.

Pract
Infere

Or we might have made the same assumption by the remark also formerly made on this case, that the squares of the discharges are nearly as the cubes of the heights, or $1500^2 : 4500^2 = 6^3 : 12{\cdot}48^3$.

And in making these first guesses, we shall do it more exactly, by recollecting that a certain variation of the mean depth d requires a greater variation of the height, and the increment will be to the height nearly as half the height to the width, as may easily be seen. Therefore, if we add to 12·48 its $\frac{6{\cdot}24}{150}$th part, or its 24th part, viz. 0·52, we have 13 for our first assumption, exceeding the truth only an inch and a half. We mention these circumstances, that those who are disposed to apply these doctrines to the solution of practical cases may be at no loss when one occurs of which the regular solution requires an intricate analysis.

It is evident that the inverse of the foregoing problems will show the effects of enlarging the section of a river, that is, will show how much its surface will be sunk by any proposed enlargement of its bed. It is therefore needless to propose such problems in this place. Common sense directs us to make these enlargements in those parts of the river where their effect will be greatest, that is, where it is shallowest when its breadth greatly exceeds its depth, or where it is narrowest (if its depth exceed the breadth, which is a very rare case), or, in general, where the slope is the smallest for a short run.

and dir
us in th
method
embank
ments.

The same general principles direct us in the method of embankments for the prevention of floods, by enabling us to ascertain the heights necessary to be given to our banks. This will evidently depend, not only on the additional quantity of water which experience tells us a river brings down during its freshes, but also on the distance at which we place the banks from the natural banks of the river. This is a point where mistaken economy frequently defeats its own purpose. If we raise our embankment at some distance from the natural banks of the river, not only will a smaller height suffice, and consequently a smaller base, which will make a saving in the duplicate proportion of the height; but our works will be so much the more durable nearly, if not exactly, in the same proportion. For by thus enlarging the additional bed which we give to the swollen river, we diminish its velocity almost in the same proportion that we enlarge its channel, and thus diminish its power of ruining our works. Except, therefore, in the case of a river whose freshes are loaded with fine sand to destroy the turf, it is always proper to place the embankment at a considerable distance from the natural banks. Placing them at half the breadth of the stream from its natural banks, will nearly double its channel; and, except in the case here mentioned, the space now detached from our fields will afford excellent pasture.

The limits of such a work as ours will not permit us to enter into any detail on the method of embankment. It would require a volume to give instructions as to the manner of founding, raising, and securing the dikes which must be raised, and a thousand circumstances which must be attended to. But a few general observations may be made, which naturally occur while we are considering the manner in which a river works in settling or altering its channel.

It must be remarked, in the first place, that the river will rise higher when embanked than it does while it was allowed to spread; and it is by that means easy to conclude to what height it will rise from the greatest height to which it has been observed to rise in its floods. When at liberty to expand over a wide valley, then it could only rise till it overflowed with a thickness or depth of water sufficient to produce a motion backwards into the valley

tical
rences.

Practical
Inferences.

quick enough to take off the water as fast as it was supplied; and we imagine that a foot or two would suffice in most cases. The best way for a prudent engineer will be to observe the utmost rise remembered by the neighbours in some gorge, where the river cannot spread out. Measure the increased section in this place, and at the same time recollect that the water increases in a much greater proportion than the section; because an increase of the hydraulic mean depth produces an increase of velocity in nearly the duplicate proportion of the depth. But as this augmentation of velocity will also obtain between the embankments, it will be sufficiently exact to suppose that the section must here be increased nearly in the same proportion as at the gorge already mentioned. Neglecting this method of information, and regulating the height of our embankments by the greatest swell that has been observed in the plain, will assuredly make them too low, and render them totally useless.

A line of embankment should always be carried on by a strict concert of the proprietors of both banks through its whole extent. A greedy proprietor, by advancing his own embankment beyond that of his neighbours, not only exposes himself to risk by the working of the waters on the angles which this will produce, but exposes his neighbours also to danger, by narrowing the section, and thereby raising the surface and increasing the velocity, and by turning the stream athwart, and causing it to shoot against the opposite bank. The whole should be as much as possible in a line; and the general effect should be to make the course of the stream straighter than it was before. All bends should be made more gentle, by keeping the embankment farther from the river in all convex lines of the natural bank, and bringing it nearer where the bank is concave. This will greatly diminish the action of the waters on the embankment, and insure their duration. The same maxim must be followed in fencing any brook which discharges itself into the river. The bends given at its mouth to the two lines of embankment should be made less acute than those of the natural brook, although by this means two points of land are left out. And the opportunity should be embraced of making the direction of this transverse brook more sloping than before, that is, less athwart the direction of the river.

It is of great consequence to cover the outside of the dike with very compact turf closely united. If it admit water, the interior part of the wall, which is always more porous, becomes drenched in water, and this water acts with its statical pressure, tending to burst the bank on the land side, and will quickly shift it from its seat. The utmost care should therefore be taken to make it and keep it perfectly tight. It should be a continued fine turf, and every bare spot should be carefully covered with fresh sod and rat-holes must be carefully closed up.

Of Straighting or Changing the Course of Rivers.

Of th
slope
quire at
the be of
a rive and
the co e-
quenc

We have seen that every bending of a river requires an additional slope in order to continue its train, or enable it to convey the same quantity of water without swelling in its bed. The effect of taking away any of these bends must be to sink the waters of the river. It is proper, therefore, to have it in our power to estimate these effects. It may be desirable to gain property by taking away the sweeps of a very winding stream; but this may be prejudicial, by destroying the navigation on such a river. It may also hurt the proprietors below, by increasing the velocity of the stream, which will expose them to the risk of its overflowing, or of its destroying its bed, and taking a new course. Or this increase of velocity may be inconsistent with the regimen of the new channel, or at least require larger dimensions than we should have given it if ignorant of this effect.

Our principles of uniform motion enable us to answer every question of this kind which can occur; and M. de Buat proposes several problems to this effect. The regular solutions of them are complicated and difficult; and we do not think them necessary in this place, because they may all be solved in a manner not indeed so elegant, because indirect, but abundantly accurate, and easy to any person familiar with those which we have already considered.

We can take the exact level across all these sweeps, and thus obtain the whole slope. We can measure with accuracy the velocity in some part of the channel which is most remote from any bend, and where the channel itself has the greatest regularity of form. This will give us the expense or discharge of the river, and the mean depth connected with it. We can then examine whether this velocity is precisely such as is compatible with stability in the straight course. If it is, it is evident that if we cut off the bends, the greater slope which this will produce will communicate to the waters a velocity incompatible with the regimen suited to this soil, unless we enlarge the width of the stream, that is, unless we make the new channel more capacious than the old one. We must now calculate the dimensions of the channel which, with this increased slope, will conduct the waters with the velocity that is necessary. All this may be done by the foregoing problems; and we may accomplish this most easily by steps. First, suppose the bed the same with the old one, and calculate the velocity for the increased slope by the general formula. Then change one of the dimensions of the channel, so as to produce the velocity we want, which is a very simple process. And in doing this, the object to be kept chiefly in view is not to make the new velocity such as will be incompatible with the stability of the new bed.

Having accomplished this first purpose, we learn, in the very solution, how much shallower this channel with its greater slope will be than the former, while it discharges all the waters. This diminution of depth must increase the slope and the velocity, and must diminish the depth of the river above the place where the alteration is to be made. How far it produces these effects may be calculated by the general formula. We then see whether the navigation will be hurt, either in the old river up the stream, or in the new channel. It is plain that all these points cannot be reconciled. We may make the new channel such, that it shall leave a velocity compatible with stability, and that it shall not diminish the depth of the river up the stream. But having a greater slope, it must have a smaller mean depth, and also a smaller real depth, unless we make it of a very inconvenient form.

The same things viewed in a different light, will show us what depression of waters may be produced by rectifying the course of a river in order to prevent its overflowing. And the process which we would recommend is the same with the foregoing. We apprehend it to be quite needless to measure the angles of rebound, in order to *compute* the slope which is *employed* for sending the river through the bend, with a view to supersede this by straighting the river. It is infinitely easier and more exact to measure the levels themselves, and then we know the effect of removing them.

Nor need we follow M. de Buat in solving problems for diminishing the slope and velocity, and deepening the channel of a river by bending its course. The expense of this would in every case be enormous; and the practices which we are about to discuss afford infinitely easier methods of accomplishing all the purposes which are to be gained by these changes.

Of Bars, Weirs, and Jetties, for raising the Surface of Rivers.

We propose, under the article WATER-WORKS, to consider in sufficient practical detail all that relates to the construction and mechanism of these and other erections

Practical Inferences.

in water; and we confine ourselves, in this place, to the mere effect which they will produce on the current of the river.

Problems, examples, and consequences of raising the surface of rivers.

We gave the name of *weir* or *bar* to a dam erected across a river for the purpose of raising its waters, whether in order to take off a draft for a mill or to deepen the channel. Before we can tell the effect which they will produce, we must have a general rule for ascertaining the relation between the height of the water above the lip of the weir or bar, and the quantity of water which will flow over.

First, then, with respect to a weir, represented in fig. 20 and fig. 21. The latter figure more resembles their usual form, consisting of a dam of solid masonry, or built of timber, properly fortified with shoars and banks. On the top is set up a strong plank FR, called the wasteboard or waster, over which the water flows. This is brought to an accurate level, of the proper height. Such voiders are frequently made in the side of a mill-course, for letting the superfluous water run off. This is properly the WASTER, or VOIDER: it is also called an OFFSET. The same observations will explain all these different pieces of practice. The following questions occur in course.

Fig. 20.

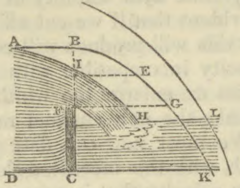

Fig. 21.

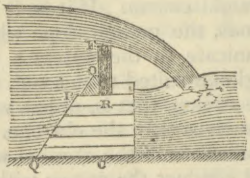


PROB. I. Given the length of an offset or wasteboard made in the face of a reservoir of stagnant water, and the depth of its lip under the horizontal surface of the water, to determine the discharge, or the quantity of water which will run over, in a second.

Let AB be the horizontal surface of the still water, and F the lip of the wasteboard. Call the depth BF under the surface h, and the length of the wasteboard l. The water is supposed to flow over into another basin or channel, so much lower that the surface HL of the water is lower, or at least not higher, than F.

If the water could be supported at the height BF, BF might be considered as an orifice in the side of a vessel. In this case, the discharge would be the same as if the whole water were flowing with the velocity acquired from the height $\frac{4}{9}$BF, or $\frac{4}{9}h$. And if we suppose that there is no contraction at the orifice, the mean velocity would be $\sqrt{2g\frac{4}{9}h}, = \sqrt{772 \times \frac{4}{9}h}$, in English inches, per second. The area of this orifice is lh. Therefore the discharge would be $lh\sqrt{772 \times \frac{4}{9}h}$, all being measured in inches. This is the usual theory; but it is not an exact representation of the manner in which the efflux really happens. The water cannot remain at the height BF; but in drawing towards the wasteboard from all sides it forms a convex surface AIH, so that the point I, where the vertical drawn from the edge of the wasteboard meets the curve, is considerably lower than B. But as all the mass above F is supposed perfectly fluid, the pressure of the incumbent water is propagated, in the opinion of M. de Buat, to the filament passing over at F without any diminution. The same may be said of any filament between F and I. Each tends, therefore, to move in the same manner as if it were really impelled through an orifice in its place. Therefore the motions through every part of the line or plane IF are the same as if the water were escaping through an orifice IF, made by a sluice let down on the water, and keeping up the water of the reservoir to the level AB. It is beyond a doubt, says he, that the height IF must depend on the whole height BF, and that there must be a certain determined proportion between them. He does not attempt to determine this proportion theoretically, but says that his experiments ascertain it with great precision to be the proportion of one to two, or that IF is always one half of BF. He says, however, that this determination was not by an immediate and direct measurement; he concluded it from the comparison of the quantities of water discharged under different heights of the water in the reservoir.

We cannot help thinking that this reasoning is very defective in several particulars. It cannot be inferred, from the laws of hydrostatical pressure, that the filament at I is pressed forward with all the weight of the column BI. The particle I is really at the surface; and considering it as making part of the surface of a running stream, it is subjected to hardly any pressure, any more than the particles on the surface of a cup of water held in the hand, while it is carried round the axis of the earth and round the sun. Reasoning according to his own principles, and availing himself of his own discovery, he should have said that the particle at I has an accelerating force depending on its slope only; and then he should have endeavoured to ascertain this slope. The motion of the particle at I has no immediate connection with the pressure of the column BI; and if it had, the motion would be extremely different from what it is: for this pressure alone would give it the velocity which M. de Buat assigns it. Now it is already passing through the point I with the velocity which it has acquired in descending along the curve AI; and this is the real state of the case. The particles are passing through with a velocity already acquired by a sloping current; and they are accelerated by the hydrostatical pressure of the water above them. The internal mechanism of these motions is infinitely more complex than M. de Buat here supposes; and on this supposition, he very nearly abandons the theory which he has so ingeniously established, and adopts the theory of Guglielmini, which he had exploded. At the same time, we think that he is not much mistaken when he asserts that the motions are nearly the same as if a sluice had been let down from the surface to I. For the filament which passes at I has been gliding down a curved surface, and has not been exposed to any friction. It is perhaps the very case of hydraulics where the obstructions are the smallest; and we should therefore expect that its motion will be least retarded.

We have therefore no hesitation in saying, that the filament at I is in the very state of motion which the theory would assign to it if it were passing under a sluice, as M. de Buat supposes. And with respect to the inferior filaments, without attempting the very difficult task of investigating their motions, we shall just say, that we do not see any reason for supposing that they will move slower than our author supposes. Therefore, though we reject his theory, we admit his experimental proposition in general; that is, we admit that the *whole* water which passes through the plane IF moves with the velocity (though not in the same direction) with which it would have run through a sluice of the same depth; and we may proceed with his determination of the quantity of water discharged.

If we make BC the axis of a parabola BEGK, the velocities of the filaments passing at I and F will be represented by the ordinates IE and FG, and the discharge by the area IEGF. This allows a very neat solution of the problem. Let the quantity discharged per second be D, and let the whole height BF be h. Let 2G be the quantity by which we must divide the square of the mean velocity in order to have the producing height. This will be less than $2g$, the acceleration of gravity, on account of the convergency at the sides and the tendency to convergence at the lip F. We formerly gave for its measure 702 inches, instead of 772, and said that the inches discharged per second from an orifice of one inch were 26·49, instead of 27·78.

Let x be the distance of any filament from the horizontal line AB. An element of the orifice, therefore (for we may give it this name), is $l dx$. The velocity of this element is $\sqrt{2Gx}$, or $\sqrt{2G} \times x^{\frac{1}{2}}$. The discharge from it is $l\sqrt{2G}\, x^{\frac{1}{2}}\, dx$, and the integral of this differential or $D = \int l\sqrt{2G}\, x^{\frac{1}{2}}\, dx = \frac{2}{3} l\sqrt{2G}\, x^{\frac{3}{2}} + C$. To determine the constant quantity C, observe that M. de Buat found by experiment that IF was in all cases $\frac{1}{2}$ BF. Therefore D must be nothing when $x = \frac{1}{2} h$; consequently $C = -\frac{2}{3} l\sqrt{2G}\left(\frac{h}{2}\right)^{\frac{3}{2}}$, and the complete integral will be $D = \frac{2}{3} l\sqrt{2G}\left[x^{\frac{3}{2}} - \left(\frac{h}{2}\right)^{\frac{3}{2}}\right]$.

Now make $x = h$, and we have

$$D = \frac{2}{3} l\sqrt{2G}\left[h^{\frac{3}{2}} - \left(\frac{h}{2}\right)^{\frac{3}{2}}\right] = \frac{2}{3} l\sqrt{2G}\left[1 - \left(\tfrac{1}{2}\right)^{\frac{3}{2}}\right] h^{\frac{3}{2}}.$$

But $1 - \left(\frac{1}{2}\right)^{\frac{3}{2}} = 0{\cdot}64645$, and $\frac{2}{3}$ of this is 0·431. Therefore, finally, $D = 0{\cdot}431\, l\sqrt{2G}\, h^{\frac{3}{2}}$.

If we now put 26·49 or 26½ for $\sqrt{2G}$, or the velocity with which a head of water of one inch will impel the water over a weir, and multiply this by 0·431, we get the following quantity, 11·4172, or, in numbers of easy recollection, 11½, for the cubic inches of water per second, which runs over every inch of a wasteboard when the edge of it is one inch below the surface of the reservoir; and this must be multiplied by $h^{\frac{3}{2}}$, or by the square root of the cube of the head of water. Thus, let the edge of the wasteboard be four inches below the surface of the water. The cube of this is 64, of which the square root is eight. Therefore a wasteboard of this depth under the surface, and three feet long, will discharge every second 8 × 36 × 11½ cubic inches of water, or $1\frac{9}{10}$ cubic feet, English measure.

The following comparisons will show how much this theory may be depended on. The first column shows the depth of the edge of the board under the surface, the second shows the discharge by theory, and the third the discharge actually observed. The length of the board was 18·4 inches. The numbers in M. de Buat's experiments are here reduced to English measure.

D.	D. Theor.	D. Exp.	E.
1·778	506	524	28·5
3·199	1222	1218	66·2
4·665	2153	2155	117·1
6·753	3750	3771	204·9

The last column is the cubic inches discharged in a second by each inch of the wasteboard. The correspondence is undoubtedly very great. The greatest error is in the first, which may be attributed to a much smaller lateral contraction under so small a head of water.

But it must be remarked, that the calculation proceeds on two suppositions. The height FI is supposed $\frac{1}{2}$ of BI; and 2G is supposed 702. It is evident, that by increasing the one and diminishing the other, nearly the same answers may be produced, unless much greater variations of h be examined. Both of these quantities are matters of considerable uncertainty, particularly the first; and it must be farther remarked, that this was not measured, but deduced from the uniformity of the experiments. We presume that M. de Buat tried various values of G, till he found one which gave the *ratios* of discharge which he observed. We beg leave to observe, that in a set of numerous experiments which we had access to examine, BI was uniformly much less than $\frac{1}{2}$; it was very nearly $\frac{2}{7}$; and the quantity discharged was greater than what would result from M. de Buat's calculation. It was farther observed that IF depended very much on the form of the wasteboard. When it was a very thin board of considerable depth, IF was very considerably greater than if the board was thick, or narrow, and set on the top of a broad dam-head, as in fig. 21.

Practical Inferences.

It may be proper to give the formula a form which will correspond to any ratio which experience may discover between BF and IF. Thus, let IF be $\frac{m}{n}$ BF. The formula will be $D = \frac{2}{3} l\sqrt{2G}\left(1 - \left(\frac{m}{n}\right)^{\frac{2}{3}}\right) h^{\frac{3}{2}}$.

Meantime, this theory of M. de Buat is of great value to the practical engineer, who at present must content himself with a very vague conjecture, or take the calculation of the erroneous theory of Guglielmini. By that theory, the board of three feet, at the depth of four inches, should discharge nearly $3\frac{1}{10}$ cubic feet per second, which is almost double of what it really delivers.

We presume, therefore, that the following table will be acceptable to practical engineers, who are not familiar with such computations. It contains, in the first column, the depth in English inches from the surface of the stagnant water of a reservoir to the edge of the wasteboard. The second column is the cubic feet of water discharged in a minute by every inch of the wasteboard.

Depth.	Discharge.	Depth.	Discharge.
1	0·403	10	12·748
2	1·140	11	14·707
3	2·095	12	16·758
4	3·225	13	18·895
5	4·507	14	21·117
6	5·925	15	23·419
7	7·466	16	25·800
8	9·122	17	28·258
9	10·884	18	30·786

When the depth does not exceed four inches, it will not be exact enough to take proportional parts for the fractions of an inch. The following method is exact.

If they be odd quarters of an inch, look in the table for as many inches as the depth contains quarters, and take the eighth part of the answer. Thus, for 3¾ inches, take the eighth part of 23·419, which corresponds to 15 inches. This is 2·927.

If the wasteboard is not on the face of a dam, but in a running stream, we must augment the discharge by multiplying the section by the velocity of the stream. But this correction can seldom occur in practice; because in this case the discharge is previously known, and it is h that we want, which is the object of the next problem.

We only beg leave to add, that the experiments which we mention as having been already made in this country, give a result somewhat greater than this table, viz. about $\frac{1}{16}$. Therefore, having obtained the answer by this table, add to it its 16th part, and we apprehend that it will be extremely near the truth.

When, on the other hand, we know the discharge over a wasteboard, we can tell the depth of its edge under the surface of the stagnant water of the reservoir, because we have $h = \left(\frac{D}{11\frac{1}{2}l}\right)^{\frac{2}{3}}$ very nearly.

We are now in a condition to solve the problem respecting a weir across a river.

Prob. II. The discharge and section of a river being given, it is required to determine how much the water will be raised by a weir of the whole breadth of the river, discharging the water with a clear fall, that is, the surface of the water in the lower channel being below the edge of the weir.

In this case we have 2G = 731 nearly, because there

Practical Inferences.

will be no contraction at the sides when the weir is the whole breadth of the river. But, further, the water is not now stagnant, but moving with the velocity $\frac{D}{S}$, S being the section of the river.

Therefore let a be the height of the weir from the bottom of the river, and h the height of the water above the edge of the weir. We have the velocity with which the water approaches the weir $= \frac{D}{l\,(a+h)}$, l being the length of the weir or breadth of the river. Therefore the height producing the primary mean velocity is $\left(\frac{D}{l\sqrt{2g}\,(a+h)}\right)^2$. The equation given a little ago will give $h=\left(\frac{D}{0{\cdot}431\,l\sqrt{2G}}\right)^{\frac{2}{3}}$, when the water above the weir is stagnant. Therefore, when it is already moving with the velocity $\frac{D}{l(a+h)}$, we shall have $h=\left(\frac{D}{0{\cdot}431\,l\sqrt{2G}}\right)^{\frac{2}{3}}-\left(\frac{D}{l\sqrt{2g}\,(a+h)}\right)^2$. It would be very troublesome to solve this equation regularly, because the unknown quantity h is found in the second term of the answer. But we know that the height producing the velocity above the weir is very small in comparison of h and of a, and, if only estimated roughly, will make a very insensible change in the value of h; and, by repeating the operation, we can correct this value, and obtain h to any degree of exactness.

To illustrate this by an example. Suppose a river, the section of whose stream is 150 feet, and that it discharges 174 cubic feet of water in a second; how much will the waters of this river be raised by a weir of the same width, and 3 feet high.

Suppose the width to be 50 feet. This will give 3 feet for the depth; and we see that the water will have a clear fall, because the lower stream will be the same as before.

The section being 150 feet, and the discharge 174, the mean velocity is $\frac{174}{150} = 1{\cdot}16$ feet $= 14$ inches nearly, which requires the height of $\frac{1}{4}$ of an inch very nearly. This may be taken for the second term of the value of h. Therefore $h=\left(\frac{D}{0{\cdot}431\,l\sqrt{2G}}\right)^{\frac{2}{3}}-\frac{1}{4}$. Now $\sqrt{2G}$ is, in the present case, 27·03, l is 600, and D is $174 \times 1728 = 300672$. Therefore $h = 12{\cdot}28 - 0{\cdot}25 = 12{\cdot}03$ nearly. Correct this value by substituting a more accurate value of the second term $\left(\frac{D}{l\sqrt{2g}(a+h)}\right)^2$, or 0·14. This will give us $h = 12{\cdot}28 - 0{\cdot}25 = 12{\cdot}03$ for a more accurate value, differing from the former about $\frac{1}{10}$ of an inch. It is needless to carry the approximation farther. Thus we see that a weir which dams up the whole of the former current of three feet deep, will only raise the waters of this river one foot.

The same rule serves for showing how high we ought to raise this weir in order to produce *any given rise* of the waters, whether for the purposes of navigation, or for taking off a draft to drive mills, or for any other service; for if the breadth of the river remain the same, the water will still flow over the weir with nearly the same depth. A very small and hardly perceptible difference will indeed arise from the diminution of slope occasioned by this rise, and a consequent diminution of the velocity with which the river approaches the weir. But this difference must always be a small fraction of the second term of our answer; which term is itself very small; and even this will be compensated, in some degree, by the freer fall which the water will have over the weir.

If the intended weir is not to have the whole breadth of the river (which is seldom necessary even for the purposes of navigation), the waters will be raised higher by the same height of the wasteboard. The calculation is precisely the same for this case. Only in the second term, which gives the head of water corresponding to the velocity of the river, l must still be taken for the whole breadth of the river, while in the first term l is the length of the wasteboard. Also $\sqrt{2G}$ must be a little less, on account of the contractions at the ends of the weir, unless these be avoided by giving the masonry at the ends of the wasteboard a curved shape on the upper side of the wasteboard. This should not be done when the sole object of the weir is to raise the surface of the waters. Its effect is but trifling at any rate, when the length of the wasteboard is considerable, in proportion to the thickness of the sheet of water flowing over it.

The following comparisons of this rule with experiment will give our readers some notion of its utility.[1]

Discharge of the Weir per second.	Head producing the velocity at the Weir.	Head producing the velocity above it.	Calculated Height of the River above the Wasteboard.	Observed Height.
Inches.	Inches.	Inches.	Inches.	Inches.
3888	7·302	0·625	6·677	6·583
2462	5·385	0·350	5·035	4·750
1112	3·171	0·116	3·055	3·166
259	1·201	0·0114	1·189	1·250

It was found extremely difficult to measure the exact height of the water in the upper stream above the wasteboard. The curvature AI extended several feet up the stream. Indeed there must be something arbitrary in this measurement, because the surface of the stream is not horizontal. The deviation should be taken, not from a horizontal plane, but from the inclined surface of the river.

It is plain that a river cannot be fitted for continued navigation by weirs. These occasion interruptions; but a few inches may sometimes be added to the waters of a river by a bar, which may still allow a flat-bottomed lighter or a raft to pass over it. This is a very frequent practice in Holland and Flanders; and a very cheap and certain conveyance of goods is there obtained by means of streams which we would think no better than boundary ditches, and unfit for every purpose of this kind. By means of a bar the water is kept up a very few inches, and the stream has free course to the sea. The shoot over the bar is prevented by means of another bar placed a little way below it, lying flat in the bottom of the ditch, but which may be raised up on hinges. The lighterman makes his boat fast to a stake immediately above the bar, raises the lower bar, brings over his boat, again makes it fast, and, having laid down the other bar again, proceeds on his journey. This contrivance answers the end of a lock at a very trifling expense; and though it does not admit of what we are accustomed to call navigation, it gives a very sure conveyance, which would otherwise be impossible. When the waters can be raised by bars, so that they may be drawn off for machinery or other purposes, they are preferable to weirs, because they do not obstruct floating with rafts, and are not destroyed by the ice.

Prob. III. Given the height of a bar, the depth of water both above and below it, and the width of the river, to determine the discharge.

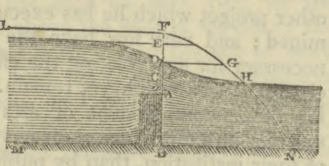
---

[1] This table from M. de Buat is expressed in French measures.

This is by no means so easily solved as the discharge over a weir, and we cannot do it with the same degree of evidence. We imagine, however, that the following observations will not be very far from a true account of the matter.

We may first suppose a reservoir LFBM (fig. 22) of stagnant water, and that has a wasteboard of the height AB. We may then determine, by the foregoing problems, the discharge through the plane EC. With respect to the discharge through the part CA, it should be equal to the product of this part of the section by the velocity corresponding to the fall EC, which is the difference of the heights of water above and below the bar; for, because the difference of Ea and Ca is equal to EC, every particle a of water in the plane CA is pressed in the direction of this stream with the same force, viz. the weight of the column EC. The sum of these discharges should be the whole discharge over the bar; but since the bar is set up across a running river, its discharge must be the same with that of the river. The water of the river, when it comes to the place of the bar, has acquired some velocity by its slope or other causes, and this corresponds to some height FE. This velocity, multiplied by the section of the river, having the height EB, should give a discharge equal to the discharge over the bar.

Fig. 22.



To avoid this complication of conditions, we may first compute the discharge of the bar in the manner now pointed out, without the consideration of the previous velocity of the stream. This discharge will be a little too small. If we divide it by the section FB, it will give a primary velocity too small, but not far from the truth. Therefore we shall get the height FE, by means of which we shall be able to determine a velocity intermediate between DG and CH, which would correspond to a weir, as also the velocity CH, which corresponds to the part of the section CA, which is wholly under water. Then we correct all these quantities by repeating the operation with them instead of our first assumptions.

M. de Buat found this computation extremely near the truth, but in all cases a little greater than observation exhibited.

We may now solve the problem in the most general terms.

PROB. IV. Given the breadth, depth, and the slope of a river, if we confine its passage by a bar or weir of a known height and width, to determine the rise of the waters above the bar.

The slope and dimensions of the channel being given, our formula will give us the velocity and the quantity of water discharged. Then, by Problem II., find the height of water above the wasteboard. From the sum of these two heights deduct the ordinary depth of the river. The remainder is the rise of the waters. For example:

Let there be a river whose ordinary depth is 3 feet, and breadth 40, and whose slope is 1½ inch in 100 fathoms, or $\frac{1}{4800}$. Suppose a weir on this river 6 feet high and 18 feet wide.

We must first find the velocity and discharge of the river in its natural state; we have $l=480$ inches, $h=36$, $\frac{1}{s}=\frac{1}{4800}$. Our formula of uniform motion gives $V=23{\cdot}45$, and $D=405216$ cubic inches.

The contraction obtains here on the three sides of the orifice. We may therefore take $\sqrt{2G}=26{\cdot}1$. (This example is M. de Buat's, and all the measures are French.) We have also a (the height of the weir) $=72$, and $2g=724$.

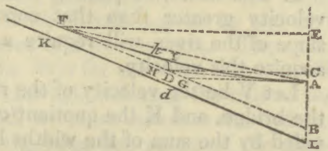
Practical Inferences.

Then the equation $h=\left(\frac{D}{0{\cdot}431\,l\sqrt{2G}}\right)^{\frac{2}{3}}-\left(\frac{D}{l\sqrt{2g}(a+h)}\right)^{2}$ becomes $h=30{\cdot}182$. Add this to the height of the weir, and the depth of the river above the sluice is 102·182 inches = 8 feet and 6·182 inches. From this take 3 feet, and there remains 5 feet and 6·182 inches for the rise of the waters.

There is, however, an important circumstance in this rise of the waters, which must be distinctly understood before we can say what are the interesting effects of this weir. This swell extends, as we all know, to a considerable distance up the stream, but is less sensible as we go away from the weir. What is the distance to which the swell extends, and what increase does it produce in the depth at different distances from the weir?

If we suppose that the slope and the breadth of the channel remain as before, it is plain, that as we come down the stream from that point where the swell is insensible, the depth of the channel increases all the way to the dam. Therefore, as the same quantity of water passes through every section of the river, the velocity must diminish very nearly in the same proportion that the section increases. But this being an open stream, and therefore the velocity being inseparably connected with the slope of the surface, it follows, that the slope of the surface must diminish all the way from that point where the swell of the water is insensible to the dam. The surface, therefore, cannot be a simple inclined plane, but must be concave upwards, as represented in fig. 23, where FKLB represents the channel of a river, and FB the surface of the water running in it. If this be kept up to A by a weir AL, the surface will be a curve FIA, touching the natural surface F at the beginning of the swell, and the line AD which touches it in A will have the slope S corresponding to the velocity which the waters have immediately before going to the weir. We know this slope, because we are supposed to know the discharge of the river and its slope and other circumstances before barring it with a dam; and we know the height of the dam H, and therefore the new velocity at A, or immediately above A, and consequently the slope S. Therefore, drawing the horizontal lines DC, AG, it is plain that CB will be the primary slope of the river, and CA, the slope S corresponding to the velocity in the immediate neighbourhood of A, because these verticals have the same horizontal distance DC. We have therefore CB : CA = S : s very nearly, and S — s : s = CB — CA : CA = AB : CA. Therefore $\mathrm{CA}=\frac{\mathrm{AB}\times s}{\mathrm{S}-s}=\frac{\mathrm{H}s}{\mathrm{S}-s}$. But DA = CA × S, by our definition of slope; therefore $\mathrm{DA}=\frac{\mathrm{HS}s}{\mathrm{S}-s}$.

Fig. 23.



This is all that we can say with precision of this curve. M. de Buat examined what would result from supposing it an arc of a circle. In this case we should have DA = DF, and AF very nearly equal to 2 AD; and as we can thus find AD, we get the whole length FIA of the swell, and also the distances of any part of the curve from the primitive surface FB of the river; for these will be very nearly in the duplicate proportion of their distances from F. Thus ID will be one fourth of AB, &c. Therefore we should obtain the depth Id of the stream in that place. Getting the depth of the stream, and knowing the discharge, we get the velocity, and can compare this with the slope of the surface at I. This should be the slope of that part of the arc of the circle. Making this comparison, he found these circumstances to be incompatible. He found that the section and swell at I, corresponding to an arc of a circle, gave a discharge nearly one fourth too great (they were as 405216 to 492142). Therefore the curve is such that AD is greater than DF, and that it is more incurvated at F than at A. He found, that making DA to DF as 10 to 9, and the curve FIA an arc of an ellipse whose longer axis was vertical, would give a very nice correspondence of the sections, velocities, and slopes. The whole extent of the swell, therefore, can never be double of AD, and must always greatly surpass AD; and these limits will do very well for every practical question. Therefore, making DF nine tenths of AD, and drawing the chord AD, and making DI one half of D *i*, we shall be very near the truth. Then we get the swell with sufficient precision for any point H between F and D, by making $FD^2 : FH^2 = ID : Hh$; and if H is between D and A, we get its distance from the tangent DA by a similar process.

It only remains to determine the swell produced in the waters of a river by the erection of a bridge or cleaning sluice, which contracts the passage. This requires the solution of

Prob. V. Given the depth, breadth, and slope of a river, to determine the swell occasioned by the piers of a bridge or sides of a cleaning sluice, which contract the passage by a given quantity, for a given length of channel.

This swell depends on two circumstances.

1. The whole river must pass through a narrow space, with a velocity proportionably increased; and this requires a certain head of water above the bridge.

2. The water, in passing the length of the piers with a velocity greater than that corresponding to the primary slope of the river, will require a greater slope in order to acquire this velocity.

Let V be the velocity of the river before the erection of the bridge, and K the quotient of the width of the river divided by the sum of the widths between the piers. If the length of the piers, or their dimension in the direction of the stream, is not very great, KV will nearly express the velocity of the river under the arches; and if we suppose for a moment the contraction (in the sense hitherto used) to be nothing, the height producing this velocity will be $\frac{K^2V^2}{2g}$. But the river will not rise so high, having already a slope and velocity before getting under the arches, and the height corresponding to this velocity is $\frac{V^2}{2g}$; therefore the height for producing the augmentation of velocity is $\frac{K^2V^2}{2g} - \frac{V^2}{2g}$. But if we make allowance for contraction, we must employ a co-efficient 2G less than $2g$, and we must multiply the height now found by $\frac{2g}{2G}$. It will then become $\left(\frac{K^2V^2}{2g} - \frac{V^2}{2g}\right)\frac{2g}{2G} = \frac{V^2}{2G}(K^2 - 1)$. This is that part of the swell which must produce the augmentation of velocity.

With respect to what is necessary for producing the additional slope between the piers, let p be the natural slope of the river (or rather the difference of level in the length of the piers) before the erection of the bridge, and corresponding to the velocity V; K^2p will very nearly express the difference of superficial level for the length of the piers, which is necessary for maintaining the velocity KV through the same length. The increase of slope therefore is $K^2p - p = p(K^2 - 1)$. Therefore the whole swell will be $\left(\frac{V^2}{2G} + p\right)(K^2 - 1)$.

These are the chief questions or problems on this subject which occur in the practice of an engineer; and the solutions which we have given may in every case be depended on as very near the truth, and we are confident that the errors will never amount to one fifth of the whole quantity. We are equally certain, that of those who call themselves engineers, and who, without hesitation, undertake jobs of enormous expense, not one in ten is able even to guess at the result of such operations, unless the circumstances of the case happen to coincide with those of some other project which he has executed, or has distinctly examined; and very few have the sagacity and penetration necessary for appreciating the effects of the distinguishing circumstances which yet remain. The society established for the encouragement of arts and manufactures could scarcely do a more important service to the public in the line of their institution, than by publishing in their transactions a description of every work of this kind executed in the kingdom, with an account of its performance. This would be a most valuable collection of experiments and facts. The unlearned practitioner would find among them something which resembles in its chief circumstances almost any project which could occur to him in his business, and would tell him what to expect in the case under his management; and the intelligent engineer, assisted by mathematical knowledge, and the habit of classing things together, would frequently be able to frame general rules. To a gentleman qualified as was the Chevalier de Buat, such a collection would be inestimable, and might suggest a theory as far excelling his as he has excelled all other writers.

We shall conclude this article with some observations on the methods which may be taken for rendering small rivers and brooks fit for inland navigation, or at least for floatage. We get much instruction on this subject from what has been said concerning the swell produced in a river by weirs, bars, or any diminution of its former section. Our knowledge of the form which the surface of this swell affects will furnish rules for spacing these obstructions in such a manner, and at such distances from each other, that the swell produced by one shall extend to the one above it.

If we know the slope, the breadth, and the depth of a river, in the droughts of summer, and have determined on the height of the floodgates, or keeps, which are to be set up in its bed, it is evident that their stations are not matters of arbitrary choice, if we would derive the greatest possible advantage from them.

Some rivers in Flanders and Italy are made navigable in some sort by simple sluices, which, being shut, form magazines of water, which, being discharged by opening the gates, raises the inferior reach enough to permit the passage of the craft which are kept on it. After this momentary rise the keeps are shut again, the water sinks in the lower reach, and the lighters which were floated through the shallows are now obliged to draw into those parts of the reach where they can lie afloat till the next supply of water from above enables them to proceed. This is a very rude and imperfect method, and unjustifiable at this day, when we know the effect of locks, or at least of double gates. We do not mean to enter on the consideration of these contrivances, and to give the methods of their construction, in this place, but refer our readers to what has been already said on this subject in the article Navigation Inland, and to what will be said in the article Water-Works. At present we confine ourselves to the single point of husbanding the different falls in the bed of the river, in such a manner that there may be everywhere a sufficient depth of water; and, in what we have to deliver on the subject, we shall take the form of an example to illustrate the application of the foregoing rules.

Suppose then a river forty feet wide and three feet deep

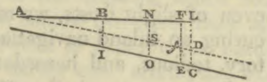
Pr cal Infe nces.

in the droughts of summer, with a slope of one in 4800. This, by the formula of uniform motion, will have a velocity = 23½ inches per second, and its discharge will be 405216 cubic inches, or 234½ feet. It is proposed to give this river a depth of not less than five feet in any place, by means of floodgates of six feet in height and eighteen feet in width.

We first compute the height at which this body of 234½ cubic feet of water will discharge itself over the floodgates. This we shall find by Prob. II. to be 30¼ inches, to which adding 72, the height of the gate, we have 102¼ for the whole height of the water above the floor of the gate; the primitive depth of the river being 3 feet, the rise or swell 5 feet 6¼ inches. In the next place, we find the range or sensible extent of this swell by Prob. I. and the observations which accompany it. This will be found to be nearly 9177 fathoms. Now, since the primitive depth of the river is three feet, there is only wanted two feet of addition; and the question is reduced to the finding what point of the curved surface of the swell is two feet above the tangent plane at the head of the swell, or how far this point is from the gate. The whole extent being 9177 fathoms, and the deviations from the tangent plane being nearly in the duplicate ratio of the distances from the point of contact, we may institute this proportion, $66\frac{1}{4} : 24 = 9177^2 : 5526^2$. The last term is the distance (from the head of the swell) of that part of the surface which is two feet above the primitive surface of the river. Therefore 9177 — 5526, or 3651 fathoms, is the distance of this part from the floodgate; and this is the distance at which the gates should be placed from each other. No inconvenience would arise from having them nearer, if the banks be high enough to contain the waters; but if they are farther distant, the required depth of water cannot be had without increasing the height of the gates; but if reasons of conveniency should induce us to place them nearer, the same depth may be secured by lower gates, and no additional height will be required for the banks. This is generally a matter of moment, because the raising of water brings along with it the chance of flooding the adjoining fields. Knowing the place where the swell ceases to be sensible, we can keep the top of the intermediate floodgate at the precise height of the curved surface of the swell by means of the proportionality of the deviations from the tangent to the distances from the point of contact.

But this rule will not do for a gate which is at a greater distance from the one above it than the 3651 fathoms already mentioned. We know that a higher gate is required, producing a more extensive swell; and the one swell does not coincide with the other, although they may both begin from the same point A. Nor will the curves even be similar, unless the thickness of the sheet of water flowing over the gate be increased in the same ratio. But this is not the case, because the produce of the river, and therefore the thickness of the sheet of water, is constant. But we may suppose them similar without erring more than two or three decimals of an inch; and then we shall have AF : AL = fF : DL; from which, if we take the thickness of the sheet of water already calculated for the other gates, there will remain the height of the gate DL.

Fig. 24.



By following these methods, instead of proceeding by random guesses, we shall procure the greatest depth of water at the smallest expense possible.

ffects reshes.

But there is a circumstance which must be attended to, and which, if neglected, may in a short time render all our works useless. These gates must frequently be open in the time of freshes; and as this channel then has its natural slope increased in every reach by the great contraction of the section in the gates, and also rolls along a greater body of water, the action of the stream on its bed must be increased by the augmentation of velocity which these circumstances will produce; and although we may say that the general slope is necessarily secured by the cills of the floodgates, which are paved with stone or covered with planks, yet this will not hinder this increased current from digging up the bottom in the intervals, undermining the banks, and lodging the mud and earth thus carried off in places where the current meets with any check. All these consequences will assuredly follow if the increased velocity is greater than what corresponds to the regimen relative to the soil in which the river holds on its course.

Practical Inferences.

and of local circumstances,

In order therefore to procure durability to works of this kind, which are generally of enormous expense, the local circumstances must be most scrupulously studied. It is not the ordinary hurried survey of an engineer that will free us from the risk of our navigation becoming very troublesome by the rise of the waters being diminished from their former quantity, and banks formed at a small distance below every sluice. We must attentively study the nature of the soil, and discover experimentally the velocity which is not inconsistent with the permanency of the channel. If this be not a great deal less than that of the river when accelerated by freshes, the regimen may be preserved after the establishment of the gate, and no great changes in the channel will be necessary; but if, on the other hand, the natural velocity of the river during its freshes greatly exceeds what is consistent with stability, we must enlarge the width of the channel, that we may diminish the hydraulic mean depth, and along with this the velocity. Therefore, knowing the quantity discharged during the freshes, divide it by the velocity of regimen, or rather by a velocity somewhat greater (for a reason which will appear by and by), the quotient will be the area of a new section. Then taking the natural slope of the river for the slope which it will preserve in this enlarged channel, and after the cills of the floodgates have been fixed, we must calculate the hydraulic mean depth, and then the other dimensions of the channel. And, lastly, from the known dimensions of the channel and the discharge (which we must now compute), we proceed to calculate the height and the distances of the floodgates, adjusted to their widths, which must be regulated by the room which may be thought proper for the free passage of the lighters which are to ply on the river. An example will illustrate the whole of this process.

illustrated by an example.

Suppose then a small river having a slope of two inches in 100 fathoms, or $\frac{1}{3600}$, which is a very usual declivity of such small streams, and whose depth in summer is two feet, but subject to floods which raise it to nine feet. Let its breadth at the bottom be eighteen feet, and the base of its slanting sides four thirds of their height. All of these dimensions are very conformable to the ordinary course of things. It is proposed to make this river navigable in all seasons by means of keeps and gates placed at proper distances; and we want to know the dimensions of a channel which will be permanent in a soil which begins to yield to a velocity of eighty inches per second, but will be safe under a velocity of twenty-four.

The primitive channel having the properties of a rectangular channel, its breadth during the freshes must be $B = 30$ feet, or 360 inches, and its depth h nine feet or 108 inches; therefore its hydraulic mean depth $d = \frac{Bh}{B + 2h} = 61{\cdot}88$ inches. Its real velocity, therefore, during the freshes, will be 38·9447 inches, and its discharge 1514169 cubic inches or 876¼ cubic feet per second. We see therefore that the natural channel will not be permanent, and will be very quickly destroyed or changed by this great velocity. We have two methods for procuring stability, viz.

Practical Inferences.

diminishing the slope, or widening the bed. The first method will require the course to be lengthened in the proportion of 24^2 to $38{\cdot}94^2$, or nearly of 38 to 100. The expense of this would be enormous. The second method will require the hydraulic mean depth to be increased nearly in the same proportion (because the velocities are nearly as $\frac{\sqrt{d}}{\sqrt{s}}$). This will evidently be much less costly and, even to procure convenient room for the navigation, must be preferred.

We must now observe, that the great velocity of which we are afraid obtains only during the winter floods. If therefore we reduce this to 24 inches, it must happen that the autumnal freshes, loaded with sand and mud, will certainly deposit a part of it, and choke up our channel below the floodgates. We must therefore select a mean velocity somewhat exceeding the regimen, that it may carry off these depositions. We shall take 27 inches, which will produce this effect on the loose mud without endangering our channel in any remarkable degree.

Therefore we have, by the theorem for uniform motion, $V = 27 = \frac{297\,(\sqrt{d} - 0{\cdot}1)}{\sqrt{s} - \mathrm{L}\sqrt{s + 1{\cdot}6}} - 0{\cdot}3\left(\sqrt{d} - 0{\cdot}1\right)$. Calculating the divisor of this formula, we find it $= 55{\cdot}884$. Hence $\sqrt{d} - 0{\cdot}1 = \frac{27}{\frac{297}{55{\cdot}884} - 0{\cdot}3} = 5{\cdot}3483$, and therefore $d = 30\frac{1}{12}$. Having thus determined the hydraulic mean depth, we find the area S of the section by dividing the discharge 1514169 by the velocity 27. This gives us 56080·368. Then we get the breadth B by the formula formerly given $B = \sqrt{\left(\frac{S}{2d}\right)^2 - 2S} + \frac{S}{2d} = 1802{\cdot}296$ inches, or 150·19 feet, and the depth $h = 31{\cdot}115$ inches

With these dimensions of the section, we are certain that the channel will be permanent; and the cills of the floodgate being all fixed agreeably to the primitive slope, we need not fear that it will be changed in the intervals by the action of the current. The gates being all open during the freshes, the bottom will be cleared of the whole deposited mud.

Station of the floodgates, &c.

We must now station the floodgates along the new channel, at such distances that we may have the depth of water which is proper for the lighters that are to be employed in the navigation. Suppose this to be four feet. We must first of all learn how high the water will be kept in this new channel during the summer droughts. There remained in the primitive channel only two feet, and the section in this case had twenty feet eight inches mean width; and the discharge corresponding to this section and slope $\frac{1}{3600}$ is, by the theorem of uniform motion, 130849 cubic inches per second. To find the depth of water in the new channel corresponding to this discharge and the same slope, we must take the method of approximation formerly exemplified, remembering that the discharge D is 130849, and the breadth B is 1760·8 at the bottom (the slant sides being four thirds). These data will produce a depth of water $= 6\frac{1}{4}$ inches. To obtain four feet therefore behind any of the floodgates, we must have a swell of $41\frac{2}{3}$ inches produced by the gate below.

We must now determine the width of passage which must be given at the gates. This will regulate the thickness of the sheet of water which flows over them when shut; and this, with the height of the gate, fixes the swell at the gate. The extent of this swell, and the elevation of every point of its curved surface above the new surface of the river, require a combination of the height of swell at the floodgate, with the primitive slope and the new velocity. These being computed, the stations of the gates may be assigned, which will secure four feet of water behind each in summer. We need not give these computations, having already exemplified them all with relation to another river.

This example not only illustrates the method of proceeding, so as to be insured of success, but also gives us a precise instance of what must be done in a case which cannot but frequently occur. We see what a prodigious excavation is necessary in order to obtain permanency. We have been obliged to enlarge the primitive bed to about thrice its former size, so that the excavation is at least two thirds of what the other method required. The expense, however, will still be vastly inferior to the other, both from the nature of the work and the quantity of ground occupied. At all events, the expense is enormous, and what could never be repaid by the navigation, except in a very rich and populous country.

There is another circumstance to be attended to. The navigation of this river by sluices must be very desultory, unless they are extremely numerous, and of small heights. The natural surface of the swell being concave upwards, the additions made by its different parts to the primitive height of the river decrease rapidly as they approach to the place A (fig. 23), where the swell terminates; and three gates, each of which raises the water one foot when placed at the proper distance from each other, will raise the water much more than two gates at twice this distance, each raising the water two feet. Moreover, when the elevation produced by a floodgate is considerable, exceeding a very few inches, the fall and current produced by the opening of the gate is such that no boat can possibly pass up the river, and it runs imminent risk of being overset and sunk in the attempt to go down the stream. This renders the navigation desultory. A number of lighters collect themselves at the gates, and wait their opening. They pass through as soon as the current becomes moderate. This would not, perhaps, be very hurtful in a regulated navigation, if they could then proceed on their voyage. But the boats bound up the river must stay on the upper side of the gate which they have just now passed, because the channel is now too shallow for them to proceed. Those bound down the river can only go to the next gate, unless it has been opened at a time nicely adjusted to the opening of the one above it. The passage downwards *may*, in many cases, be continued, by very intelligent and attentive lockmen; but the passage up *must* be exceedingly tedious. Nay, we may say, that *while* the passage downwards is continuous, it is but in a very few cases that the passage upward is practicable. If we add to these inconveniences the great danger of passes during the freshes, while all the gates are open, and the immense and unavoidable accumulations of ice, on occasion even of slight frosts, we may see that this method of procuring an inland navigation is amazingly expensive, desultory, tedious, and hazardous. It did not therefore merit, on its own account, the attention we have bestowed on it. But the discussion was absolutely necessary, in order to show what must be done in order to obtain effect and permanency, and thus to prevent us from engaging in a project which, to a person not duly and confidently informed, is so feasible and promising. Many professional engineers are ready, and with honest intentions, to undertake such tasks; and by avoiding this immense expense, and contenting themselves with a much narrower channel, they succeed: witness the old navigation of the river Mersey. But the work has no duration; and, not having been found very serviceable, its cessation is not matter of much regret. The work is not much spoken of during its continuance. It is soon forgotten, as well as its failure, and engineers are found ready to engage for such another.

It was not a very refined thought to change this imperfect mode for another free from most of its inconveniences. A boat was brought up the river, through one of these gates, only by raising the waters of the inferior reach, and depressing those of the upper: and it could not escape observation, that when the gates were far asunder, a vast body of water must be discharged before this could be done, and that it would be a great improvement to double each gate, with a very small distance between. Thus a very small quantity of water would fill the interval to the desired height, and allow the boat to come through; and this thought was the more obvious, from a similar practice having preceded it, viz. that of navigating a small river by means of double bars, the lowest of which lay flat in the bottom of the river, but could be raised up on hinges. We have mentioned this already; and it appears to have been an old practice, being mentioned by Stevinus in his valuable work on sluices, published about the beginning of the seventeenth century; yet no trace of this method is to be found of much older dates. It occurred, however, accidentally, pretty often in the flat countries of Holland and Flanders, which being the seat of frequent wars, almost every town and village was fortified with wet ditches, connected with the adjoining rivers. Stevinus mentions particularly the works of Condé, as having been long employed, with great ingenuity, for rendering navigable a very long stretch of the Scheldt. The boats were received into the lower part of the fossee, which was separated from the rest by a stone batardeau, serving to keep up the waters in the rest of the fossee about eight feet. In this were a sluice and another dam, by which the boats could be taken into the upper fossee, which communicated with a remote part of the Scheldt, by a long canal. This appears to be one of the earliest locks.

Int uc- tion locks

In the first attempt to introduce this improvement in the navigation of rivers already kept up by weirs, which gave a partial and interrupted navigation, it was usual to avoid the great expense of the second dam and gate, by making the lock altogether detached from the river, within land, and having its basin parallel to the river, and communicating by one end with the river above the weir, and by the other end with the river below the weir, and having a floodgate at each end. This was a most ingenious thought; and it was a prodigious improvement, free from all the inconveniences of currents, ice, &c. &c. It was called a *schlussel*, or lock, with considerable propriety; and this was the origin of the word *sluice*, and of our application of its translation *lock*. This practice being once introduced, it was not long before engineers found that a complete separation of the navigation from the bed of the river was not only the most perfect method for obtaining a sure, easy, and uninterrupted navigation, but that it was in general the most economical in its first construction, and subject to no risk of deterioration by the action of the current, which was here entirely removed. Locked canals, therefore, have almost entirely supplanted all attempts to improve the natural beds of rivers; and this is hardly ever attempted except in the flat countries, where they can hardly be said to differ from horizontal canals.

Concl ing ob vation

The attentive reader must have observed our anxiety to render this dissertation worthy of his notice, by making it practically useful. We have on every occasion appealed from all theoretical deductions, however specious and well supported, to fact and observation of those spontaneous phenomena of nature which are continually passing in review before us in the motion of running waters. Resting in this manner our whole doctrines on experiment, on the observation of what really happens, and what happens in a way which we cannot or do not fully explain, these spontaneous operations of nature came insensibly to acquire a particular value in our imagination. It has also happened in the course of our reflections on these subjects, that these phenomena have frequently presented themselves to our view in groups, not less remarkable for the extent and the importance of their consequences, than for the simplicity, and frequently the seeming insignificancy, nay frivolity, of the means employed. Our fancy has therefore been sometimes warmed with the view of a something, an

> Ens agitans molem, et magno se corpore miscens.

This has sometimes made us express ourselves in a way that is susceptible of misinterpretation, and may even lead into a mistake of our meaning.

We therefore find ourselves obliged to declare, that by the term NATURE, which we have so frequently used *con amore*, we do not mean that indescribable idol which the self-conceit and vanity of some philosophers or pretended philosophers have set up and ostentatiously worshipped, that *ens rationis*, that creature of the imagination, which has long been the object of cool contemplation in the closet of the philosopher, and has shared his attention with many other playthings of his ever-working fancy. By Nature we mean that admirable system of general laws, by which the adored Author and Governor of the universe has thought fit to connect the various parts of this wonderful and goodly frame of things, and to regulate all their operations.

We are not afraid of continually appealing to the laws of nature; and, as we have already observed in the article PHILOSOPHY, we consider these general laws as the most magnificent displays of Infinite Wisdom, and the contemplation of them as the most cheering employment of our understandings.

> Igneus est illis vigor et cœlestis origo
> Seminibus.

At the same time we despise the cold-hearted philosopher who stops short here, and is satisfied, perhaps inwardly pleased, that he has completely accounted for every thing by the laws of unchanging nature; and we suspect that this philosopher would analyse with the same frigid ingenuity, and explain by irresistible στοργὴ, the tender attachment of her whose breast he sucked, and who by many anxious and sleepless nights preserved alive the puling infant. But let us rather listen to the words of him who was the most sagacious observer and the most faithful interpreter of nature's laws, our illustrious countryman Sir Isaac Newton.

"Elegantissima hæcce rerum compages non nisi consilio et *dominio* entis sapientissimi et potentissimi oriri potuit. Omnia, simili constructa consilio, suberunt *unius* dominio. Hic omnia regit, non ut *anima mundi*, sed ut universorum dominus. Propter dominium suum, dominus deus παντοκράτωρ nuncupatur. Deus ad servientes respicit, et *deitas* est dominatio dei, non in corpus proprium, uti sentiunt quibus deus est natura seu anima mundi, sed in servos. Deus summus est ens eternum, infinitum, absolute perfectum. Ens utcunque perfectum, at sine dominio, non est dominus deus. Hunc cognoscimus, solummodo per proprietates ejus et attributa. Attribuuntur ut ex phenomenis dignoscuntur. Phenomena sunt sapientissimæ et optimæ rerum structuræ, atque causæ finales. Hunc admiramur ob perfectiones; hunc veneramur et colimus ob dominium."

Our readers will probably be pleased with the following list of authors who have treated professedly of the motions of rivers: Guglielmini *De Fluviis et Castellis Aquarum*—*Danubius Illustratus*; Grandi *De Castellis*; Zendrini *De Motu Aquarum*; Frisius *De Fluviis*; Lecchi, *Idrostatica i Idraulica*; Michelotti, *Sperienze Idrauliche*; Belidor, *Architecture Hydraulique*; Bossut, *Hydrodynamique*; Buat, *Hydraulique*; Silberschlag, *Théorie des Fleuves*; *Lettres de* M. L'Epinasse *au P. Frisi touchant sa Théorie des Fleuves*; *Tableau des Principales Rivières du Monde*, par

Genetté; Stevins *Sur les Ecluses; Traité des Ecluses*, par Boulard, *qui a remporté le Prix de l'Acad. de Lyons*; Bleiswyck, *Dissertatio de Aggeribus*; Bossut et Viallet *Sur la Construction des Digues*; Stevin, *Hydrostatica*; Tielman van der Horst, *Theatrum Machinarum Universale*; De la Lande *Sur la Canaux de Navigation.* Racolta di Autori chi trattano del Moto dell' Acque, 3 tom. 4to; Firenze, 1723. This most valuable collection contains the writings of Archimedes, Albizi, Galileo, Castelli, Michelini, Borelli, Montanari, Viviani, Cassini, Guglielmini, Grandi, Manfredi, Picard, and Narduci; and an account of the numberless works which have been carried on in the embankment of the Po. A continuation of this collection, containing many important papers, was published at Bologna in 1823, in six volumes. Coulomb, *Expériences sur la Cohérence des Fluides*, &c. in volume iii. of the Memoirs of the Institute, Class of Physical and Mathematical Sciences; Girard, *Essai sur le Mouvement des Eaux courantes, Mémoires sur le Canal de l'Ourcq*, and *Mémoires sur les Canaux de Navigation;* Prony, *Nouvelle Architecture Hydraulique*, and *Recherches Physico-Mathématiques sur la Théorie des Eaux courantes;* Venturi *Sur la Communication latérale du Mouvement des Fluides;* Eytelwein, *Handbuch der Mechanik und der Hydraulik;* De Fontaine, *Travaux du Fleuve du Rhin;* Bidone, *Expériences sur la Dépense des Réservoirs*, in volume xxviii. of the Memoirs of the Academy of Turin; Rennie's two Reports on Hydraulics, in the Transactions of the third and fourth meetings of the British Association. (B. B. B.)

River-Water. This is generally much softer and better accommodated to economical purposes than spring water. For though rivers proceed originally from springs, yet, by their rapid motion, and by being exposed during a long course to the influence of the sun and air, the earthy and metallic salts which they contain are decomposed, the acid flies off, and the terrestrial parts precipitate to the bottom. Rivers are also rendered softer by the vast quantity of rain water, which, passing along the surface of the earth, is conveyed into their channels. But all rivers carry with them a great deal of mud and other impurities; and when they flow near large and populous towns, they become impregnated with a number of heterogeneous substances, in which state the water is certainly unfit for many purposes; yet, by remaining for some time at rest, all the feculencies subside, and the water becomes sufficiently pure for most of the common purposes of life. River-water may be rendered still purer by filtration through sand and gravel.

RIVERHEAD, a town of the county of Kent, in the lathe of Sutton and hundred of Codsheath, twenty-two miles from London. The river Darent, which rises within the parish, has given its name to it. In this parish is the elegant seat of Lord Amherst, called Montreal. A new church in the Gothic style has been lately erected and consecrated. It is situated within the parish of Seven Oaks. The population was in 1801, 750; in 1811, 1012; in 1821, 1216; and in 1831, 1420.

RIVOLI, a city of the kingdom of Sardinia, in Italy, in the province of Piedmont. It is situated at the south foot of the Alps, on the great road over those mountains by way of Mount Cenis. A remarkable castle near it was long the place of residence of King Victor Amadeus, after his abdication of the throne, and he died there in 1732. The prospect from this castle, comprehending a view of the city of Turin, and the beautiful country surrounding it, is peculiarly exciting. The population consists of 6100 inhabitants, who are occupied in the manufactures of silk, linen, and woollen goods, of various kinds.

ROAD, in *Navigation*, a bay or place of anchorage, at some distance from the shore, whither vessels occasionally repair to receive intelligence, orders, or necessary supplies, or to wait for a fair wind. The excellence of a road consists chiefly in its being protected from the reigning winds and the swell of the sea, in having a good anchoring ground, and being at a competent distance from the shore. Those which are not sufficiently protected are termed *open roads*.

ROAD-MAKING. There are few departments of practical mechanics in which every individual, at some period or other of his life, is more immediately interested than in the management of roads and pavements. The mechanical theory of the motions of wheel-carriages, and of the nature of the frictions and resistances that they have to overcome, as relating to the ultimate objects for which roads are constructed, may naturally constitute the first section of an essay on this subject; the second will naturally comprehend the best arrangement of the means for attaining those objects, by the form and construction of such roads and pavements as appear to be the most eligible under various circumstances; and the third may be devoted to some historical illustrations of the principal roads which exist, or which have existed, in various parts of the world.

Sect. I.—*Of the Objects of Roads.*

The grand object of all modern roads is the accommodation of wheel-carriages. The construction of footpaths and of bridle-roads is so simple as to require very little separate consideration; except that, in cities and towns, the convenience of the inhabitants requires that some pains should be taken to avoid dust, and has generally been a reason for employing pavements in preference to gravel roads, which might in some other respects be more eligible.

For facilitating the motion of carriages, the most essential requisite is to have the road as smooth, and as hard, and as level as possible. The wheels of carriages are principally useful in diminishing the friction of the materials; a dray sliding without wheels, even on a railroad of greased and polished iron, would have to overcome a friction as much greater than that of the wheel on its axle, as the diameter of the wheel is greater than that of the axle. The wheels assist us also in drawing a carriage over an obstacle; for the path which the axis of the wheel describes is always smoother and less abrupt than the surface of a rough road, on which the wheel rolls, and so much the smoother as the wheel is larger, since the portions of larger circles, which constitute the path in question, are less curved than those of smaller ones.

But in all common cases of roads not extremely hard, by far the greater part of the resistance actually exhibited by a road to the motion of a carriage, is that which depends on the continual displacement of a portion of the materials from their inelasticity, which causes them to exert a continual pressure on the fore part of the wheel, without rising behind it to propel it forwards by its re-action, as an elastic substance would do. Hence, in a soft sand, although the axles of the wheels may move in a direction perfectly horizontal, the draught becomes extremely heavy. The more the wheel sinks, the greater is the resistance; and if we suppose the degree of elasticity of the materials, and their immediate resistance at different depths, to be known, we may calculate the whole effect of their action on the wheel, and the force that is required to displace them, in the progressive motion of the carriage. Thus, if the materials were perfectly inelastic, acting only on the preceding half of the immersed portion of the wheel, and their immediate pressure or resistance were simply proportional to the depth, like that of fluids, or that of elastic substances compressed, the horizontal resistance would be to the weight nearly as two fifths of the length of the part immersed at once, in the newly formed rut, to the diameter of the wheel; or, on a still more probable supposition respecting the greater resistance of the more deeply-seated parts of the rut, about half as much as this, or as about one fifth of the length of the part immersed in the rut to the diameter. Thus, if a coach or waggon, weighing sixty hundredweight, supported by wheels four feet in diameter, formed a new rut, an inch deep, in a smooth road, the length of the part immersed being about fourteen inches, the resistance would be about $\frac{1}{17}$th of the weight, upon the lowest supposition that is at all admissible, and more probably about one ninth, or from six to seven hundredweight at least; and if the rut were two inches deep, the resistance would be half as much more. But, on any supposition, the increased height, and even the increased breadth, of the wheel, is calculated to diminish the resistance, by diminishing the depth of the part immersed; thus, if a wheel were made four times as high, the length of the part immersed, considering the road as an imperfect fluid, would be doubled, and the resistance would be diminished, theoretically speaking, to about half of its former magnitude; and if the breadth were increased from one to eight, the length of the part immersed would be diminished to about a half, and the resistance would in this case also be reduced to a half.

In soft and boggy soils, as well as in sandy roads, this consideration is of great importance; and the wheels employed for removing heavy weights, in such cases, ought to be as high and as broad as possible consistently with sufficient lightness and economy. But whether a broad, and, at the same time, a low roller, possesses any advantages above a narrow coach-wheel, is a matter much more questionable: it must be remembered that a narrow wheel may often run between stones, where a broader would have to pass over them; and there appears to be no theoretical reason for preferring a low roller, except with respect to a single pair of wheels, as affording a more convenient attachment for the shafts in a moderate inclination, which is both more favourable to the exertion of the horses, and more effective in overcoming the friction; since it has been demonstrated that the angle affording the most advantageous line of draught is exactly the same as the inclination of a plane along which the carriage would just begin to descend by its own weight on the same kind of surface. In fact, however, there is no necessity for fixing the axle-tree precisely in the line of draught; and the principal reason for having the fore wheels lower than the others is for the convenience of turning the carriage more abruptly. A very accurate practical road-maker has observed, that a good road never suffers from narrow wheels with moderate weights not in rapid motion, but that it is equally worn by the rapid driving of heavy stage-coaches, and by the slow grinding of the conical rollers of overloaded, broad-wheeled waggons.

Such being the operations of the wheels of carriages on sandy or on rough roads, it is easy to perceive how much the hardness and smoothness of the surface must facilitate the draught; it is obvious also that the same qualities must be equally conducive to the durability of the road, since the inequalities will always cause the carriage to fall on it with a certain impetus after being elevated by the irregularities, and the same shock which strains the carriage will also tend to wear away the road still more where it is lowest; and, on the other hand, the resistance of the soft materials before the wheel will tend to tear up the road, as it causes the wheel to thrust them before it.

It happens not very uncommonly that the interests of the traveller and the postmaster are somewhat at variance with respect to the qualities of a road. The French postilion keeps to the rough pavement as long as the aching limbs of the ladies in the carriage will allow them to be silent, except when, in going down hill, he saves himself the trouble of locking the wheel, by bringing it to the soft edge of the ditch or kennel; and the horses of the Parisian cabriolets, in their excursions to the suburbs, have sagacity enough to incline always to the pavement, when their drivers allow them to have a will of their own; while a single horseman, on the contrary, more commonly finds his steed on the gravel road, if he happens to leave him to his own direction. In Great Britain the roads are commonly managed by commissioners, who have no community of interest with the innkeepers; on the Continent they are universally under the immediate direction of the different governments, who also appoint the postmasters, while the carriages are almost as uniformly the property of particular individuals, who have no immediate influence on the management of the roads; and this diversity may perhaps explain, in some measure, the different systems of road-making which prevail on the opposite sides of the channel. But it may be said of roads as of governments, "that which is best administered is best;" whether a very smooth pavement not too slippery, or a very hard gravel road not worn into great inequalities.

SECT. II.—*Of the Mechanical Formation of Roads.*

The only strongly-marked division of the different kinds of roads depends on their being paved or gravelled; but each of these classes admits of considerable diversity in the principles on which the road is constructed. The theory of pavement appears to be extremely simple; the stones, however, may be either small or large; the former being understood to be employed without previous preparation of their shape, as in the inferior kind of work which is called "pitching" in the west of England; the latter being more or less cut to fit each other, whether in the form of thick rough blocks, not very remote from cubes, or of flat and smooth flagstones. In the cities of Great Britain the former are commonly used for horse-pavements, and the latter for foot-passengers; but in Florence the whole breadth of the streets is paved with flagstones placed diagonally, and in Naples the surfaces are nearly as smooth; in both these cases it is necessary to roughen the stones frequently with chisels wherever there is a hill or a bridge, in order to prevent the horses slipping, but in both cities the horses from habit are sufficiently sure-footed, even when running with some rapidity. In Milan both kinds of pavements are mixed in the same streets; the smooth in two double lines, for the wheels of carriages coming and going, and the rougher in the intermediate parts, for the feet of the horses, as in the British railroads. But in none of these cities is there much heavy traffic to wear these well-arranged surfaces into such inequalities as would probably soon be observed in the streets of London if they were so delicately formed; although, until this deterioration actually took place, the locomotion would be luxurious both for the horses and for the passengers, and only ruinous to the coachmakers. The Romans used large and heavy blocks for their roads, cutting them on the spot into such forms as enabled them to be best adjusted to those of the neighbouring stones, though seldom exactly rectangular in their surfaces; and even at Pompeii, where the ruts are worn half through the depth of the blocks, the bottom remains tolerably even, in a longitudinal direction, at least as much so as would be required for carts and other carriages of business.

Our more particular object, however, at present, is the consideration of gravel-roads rather than of pavements; the word gravel being here understood to mean in general all stone broken small, whether by nature or by art. The improvement of such roads has long been a subject of great interest with the agricultural and commercial inhabitants of Great Britain. It was soon after the year 1700 that a part of the charge of repairing roads was taken off the respective parishes through which they pass, and levied on the general traveller by means of turnpike-gates; but it was for many years a complaint that the roads were little, if at all, fundamentally improved by the expenditure of the money so raised. This complaint is very energetically advanced in a Dissertation concerning the present State of the High Roads of England, especially of those near London, wherein is proposed a new Method of Repairing and Maintaining them; read before the Royal Society in the winter of 1736–37, by Robert Phillips, and printed in a small separate volume. The author's great object is to recommend washing the roads by a constant stream, if possible, and at any rate, washing the materials of which they are composed. In this respect, notwithstanding the existence of single roads so situated that the effects of water upon them have been very beneficially introduced, his plans for the universal employment of water have been altogether superseded by later experience; but he remonstrates, with great propriety, against the practice, which has, however, continued to prevail so generally even of late years, of laying down large heaps of unprepared gravel, to be gradually consolidated into a harder mass, at the expense of the intolerable labour of the poor animals that are obliged to grind it down. As an illustration of the good effect of water, he mentions that even the sediment deposited by it at the bottom of Fleetditch, which was supposed to be a soft mud, and to require removal when the ditch was filled up, proved in fact to be a hard gravelly substance, which afterwards afforded an excellent foundation for the roads and buildings supported by it.

The attention of the public has been more lately directed to the subject of roads and carriages, by several essays which appeared in the Communications to the Board of Agriculture; they principally belong to the names of Beatson, Wright, Jessop, Hall, Wilkes, Erskine, Ellis, Cumming, Whetley, Amos, and Booth: the most remarkable are Mr Wilkes's Remarks on the Advantages of Concave Roads; Mr Ellis's on Washing Roads; Mr Wilkes's on Railways; and Mr Cumming's on Wheel-Carriages; showing particularly the disadvantage of broad conical wheels, and the historical progress of the practice of bending the line of the axes.

But all these improvements, whether real or imaginary, have since been in a great measure superseded by the ingenuity and success of Mr Loudon Macadam, a gentleman whose practice is in general principally to be applauded for its obvious simplicity and economy, though he has also had the merit of discovering that the simplest and cheapest methods, in particular cases, especially in that of boggy soils, are also the most scientific and the most effectual. The practical observations, which are to be here inserted, cannot therefore be so well expressed in any other form, as in that of an abstract of Mr Macadam's own directions.

Mr Macadam's leading principles are (Remarks, p. 37), "that a road ought to be considered as an artificial flooring, forming a strong, smooth, solid surface, at once capable of carrying great weights, and over which carriages may pass without meeting any impediment."

He proceeds to give directions for repairing an old road and for making a new one, in the form of a communication to a committee appointed by the House of Commons, in the year 1819, with some subsequent corrections.

No additional materials, he observes, are to be brought upon a road, unless in any part of it there be not a quantity of clean stone equal to ten inches in thickness.

The stone already in the road, supposing it to have been made in the usual manner, is to be loosened, and broken so that no piece may exceed SIX OUNCES in weight; the road is then to be laid as flat as possible, leaving only a fall of three inches from the middle to the sides when the road is thirty feet wide. The stones, thus loosened, are to be dragged to the side by a strong heavy rake, with teeth two inches and a half in length, and there broken; but the stones are never to be broken on the road itself.

When the great stones have been removed, and none are left exceeding six ounces in weight, the surface is to be made smooth by a rake, which will also settle the remaining materials into a better consistence, bringing up the stone, and letting the dirt fall down into its place.

The road being so prepared, the stone that has been broken by the side is then to be carefully spread over it: this operation requires very particular attention, and the future quality of the road will greatly depend on the manner in which it is performed; the stone must not be laid on in shovels-full, but scattered over the surface, one shovelfull following another, and being spread over a considerable space.

Only a small part of the length of the road should be *lifted* in this manner at once; that is, about two or three yards; five men in a gang should be employed to *lift* it all across, two continually digging up and raking off the large stones, and preparing the road for receiving them again, and the other three breaking them at the side of the road. It may, however, happen that the surveyor may see cause to distribute the labour in a proportion somewhat different.

The only proper method of breaking stones, in general, both for effect and for economy, is in a sitting posture. The stones are to be placed in small heaps, and women, boys, and old men past hard labour, may sit down and break them with small hammers into pieces not exceeding *six ounces* in weight. When the heavy work of a quarry can be performed by men, and the lighter by their wives and children, the stone can be obtained by contract for two thirds of the former prices, although the stones were then left four times as large. It has also been recommended by Mr Macadam and others (p. 35), that the largest stone employed should not exceed the measure of an inch in its greatest dimensions, or, in other words, that it should be capable of being contained in a sphere of about an inch in diameter, which would seldom weigh more than a single ounce.

In some cases it would be unprofitable to lift and relay a road, even if the materials should have been originally too large; for example, the road betwixt Bath and Cirencester was made of large stones, but so friable, that in lifting they would have fallen into sand; in this case Mr Macadam merely had the higher parts cut down, and replaced when sifted (p. 107), and the surface kept smooth, until those materials were gradually worn out; and they were afterwards replaced by stone of a better quality, properly prepared. At Egham it was necessary to remove the whole road, in order to separate the small portion of valuable materials from the mass of soft matter in which they were enveloped, and which was carried away, at a considerable expense, before a good road could be made. But although freestone is by no means calculated to make a durable road, yet by judicious management it may be made to form a very good road as long as it lasts. (P. 103.)

Whenever new stone is to be laid on a road already consolidated, the hardened surface is to be loosened with a pick, in order to enable the fresh materials to unite with the old.

A new road, however well it may have been made, will always receive the impressions of the carriage-wheels until it is hardened; a careful person must, therefore, attend the road for some time, in order to rake in the tracks made by the wheels; that is, as long as any loose materials are left that can be so employed.

It is always superfluous, and generally injurious, to add to the broken stone any mixture of earth, clay, chalk, or any other matter that will imbibe water and be affected by frost, or to lay any thing whatever on the clean stone for the purpose of binding it; *for good stone, well broken, will always combine by its own roughness into a solid substance*, with a smooth surface, that will not be affected by the vicissitudes of weather, or disfigured by the action of wheels, which, as they pass over it without a jolt, will consequently be incapable of doing it any considerable injury.

The experience of the year 1820 strongly confirmed the inutility and inconvenience of employing chalk with the stone. In January, when a hard frost was succeeded by a sudden thaw, a great number of roads broke up, and the wheels of the carriages penetrated into the original soil; in particular, it was observed that all the roads of which chalk was a component part became nearly impassable; and even roads made over chalky soils gave way in most places. But not one of the roads that had been thoroughly made after these directions was observed to give way. (P. 44–46.)

The tools required for lifting roads are, 1. Strong *picks*, but short from the handle to the point; 2. small *hammers*, weighing about a pound, with a face the size of a shilling, well steeled, and with a short handle; 3. *rakes*, with wooden heads, ten inches in length, and with iron teeth about two and a half inches long, and very strong, for raking out the large stones when the road is broken up, and for keeping it smooth after it has been finished, and while it is consolidating; 4. very light broad-mouthed *shovels*, to spread the broken stones, and to form the road.

The whole expense of lifting and newly forming a rough road, to the depth of four inches, has generally been from a penny to twopence per square yard, being more or less according to the quantity of stone to be broken. With proper tools, and by proper arrangements, stone may be broken for tenpence or a shilling per ton, including, in some cases, the value of the stone itself. A very material advantage of Mr Macadam's method is the introduction of a much greater proportion of human labour, instead of the work of horses; formerly one fourth of the whole expense was paid, in the district of Bristol, for men's labour, and three fourths for that of horses; now, on the contrary, one fourth only is paid for horses' labour, and the other three to men, women, and children.

Mr Macadam argues very strongly against the old opinion of the necessity of placing a quantity of large stones as a foundation, to carry the road over a wet subsoil. He says, that whatever be the nature of the soil, if it be previously " made quite dry," and a covering impenetrable to rain placed over it, the thickness of the covering needs only to depend on its own capability of becoming impervious. Large stones, he says, will constantly work up by the agitation of the traffic on the road, and leave vacuities for the reception of water; and the only way of keeping the stones in their places is to have them of a uniform size. A rocky bottom causes a road to wear out much the faster [acting, probably, as a lower millstone in facilitating the operation of grinding]. " It is a known fact, that a road lasts much longer over a morass than when made over rock. In the neighbourhood of Bridgewater, for example, the materials consumed on a rocky road, when compared with those which are required for a similar road made over the naked surface of the soil, are in the proportion of seven to five."

In the summer of 1819, upon some new roads made in Scotland, more than three feet of materials, of various dimensions, were laid down; and more than two thirds of them, according to our author, were worse than wasted. In such an arrangement, the water generally penetrates to the bottom of the trench made to receive the road, and remains there to do mischief upon every change of weather.

To prevent such inconveniences, it is necessary, in wet soils, either to make drains to lower ground, or to raise the road above the general level, instead of making a trench to receive the stones; and from the penetration of rain the solidity of the road itself must protect it. A well-made road, not quite four inches in thickness, was found to have kept the earth below it dry in the parish of Ashton near Bristol but six, eight, or ten inches of materials are generally required to make a firm road; being laid on in successive layers of about two inches in thickness, all well broken, well cleaned, and well sized. Sometimes, indeed, a much greater depth of stone than this is required: in a road, for example, which was made from Lewes to East Bourn, entirely upon Mr Macadam's principles, as much as three feet of materials were required in many parts before the road could be sufficiently consolidated; it was, however, ultimately made excellent, though at an expense of not much less than a thousand pounds a mile.

Mr Macadam maintains that the quantity of stone required for paving is fully sufficient to make an excellent gravel road in any part of the world; and in almost every case, materials equally good can be obtained for roads at a still cheaper rate; commonly, indeed, at one tenth of the expense of pavements. It is, however, in steep ascents that pavements are most objectionable; at the north end of Blackfriars Bridge, more horses are said to fall and receive injury than at any other place in the kingdom. In the suburbs of Bristol the pavements have lately been converted into roads with great success. It is probable that neither the inhabitants of these suburbs nor their housemaids were much consulted on the occasion, although justice seems to require that the pedestrian order should not be altogether sacrificed to the equestrian without their consent; but, in fact, the inhabitants of these *ci-devant* streets are said to be well satisfied with the change; and we seem in danger, from the opposition of contending theories, of having all the streets of our cities dug up, and many of our country roads, on the other hand, encumbered with pavements. Mr Macadam received a new encouragement from parliament to the amount of L.4000.

We find some further confirmations and illustrations of Mr Macadam's principles and precepts in the Report of the former Committee of the House of Commons, as reprinted in his Remarks.

This gentleman, it seems, arrived from America in the year 1783, at the time when many new roads were making in Scotland (p. 97); he was then appointed a commissioner of the roads, and studied the subject in that capacity there; he afterwards resided chiefly in Bristol, and was induced to take charge of the roads of that district as a surveyor in 1816, because it was only in that situation that he could carry his principles into practice, and make the necessary experiments for establishing them. He observed in his travels, that the mixture of clay and chalk with the materials of roads was the almost universal cause of their failure; and he convinced himself that, by a proper application of materials, a good road might be made in every country. His improvements have been very generally adopted in the west and the south of England, and principally under his own direction or under that of his family. They had superintended more than 300 miles of road, and twice as many more had been improved by their advice and influence. Sober, active, and well-informed sub-surveyors he considers as the most important of all materials for a good road; and among the extrinsic arrangements which are often required, he thinks the union of different trusts into a single one the most likely to be generally beneficial.

The operation of washing gravel Mr Macadam has not found eligible, because it is more expensive than screening or sifting, and less effectual; for about London the common gravel is not capable of being cleaned by any ordinary washing, though the Thames gravel, where it can be procured, is generally clean and serviceable. Coarse gravel broken, he says, is preferable to fine, as it consolidates more perfectly into a single mass. The old practice of putting a heap of unprepared gravel along the middle of the road, and letting it work its own way gradually to the sides, he thinks every way reprehensible.

The objection to a very convex road is, that travellers only use the middle of it, which is therefore worn into three furrows by the string of horses and by the wheels; if the road is flatter, it becomes worn more equally. Ditches, he observes, only require to be so deep that the surface of the water in them may be a few inches below the level of the road; the farmer often makes them dangerously deep, on account of the value of the mould that is dug out of them. Mr Macadam would prefer a bog to any other foundation for a road, provided that it would allow a man to walk over it; and he justly observes, that the resistance to the motion of a carriage would not be materially affected by the foundation, if the road were well made. From Bridgewater to Cross, a part of the road shakes when a carriage passes over it; yet the consumption of materials is less there than on the limestone rock in the neighbourhood. He does not use any faggots in such cases, nor any stones larger than six ounces in weight; and these never sink in the bog, but unite into one mass like a piece of timber, which rests on it. He makes such a road generally at three different times; and he always prefers working in weather not very dry. The surveyors are directed to carry a pair of scales and a six-ounce weight in their pockets, as a check upon the workmen.

Mr Macadam has generally found reason to approve the usual regulation respecting carriage-wheels; but he thinks broad wheels less advantageous to roads than is commonly supposed. He suggests that the tolls might always be fairly made proportional to the exact number of horses employed; except that the waggoners should be encouraged to harness them in pairs rather than in a line. The conical form of broad wheels he thinks very injurious.

Clean flints from the sea-side are among the best materials for roads, and might often be procured cheap by canals; granite chippings also, brought as ballast, are excellent; and when the middle of the road has been well made with good stones, the sides may often be left for a few feet less abundantly provided with them, as they are naturally much less exposed to wear.

Of the other evidence produced to the committee of the House of Commons, there is much that gives us valuable information respecting the economy of horses and carriages in general, and some that deserves to be noticed, as affording partial exceptions to the universal adoption of the system introduced by Mr Macadam.

Mr Waterhouse observes (p. 85), that stage-coach horses generally last about four years in the neighbourhood of London, and about six in remoter parts. He agrees with Mr Macadam, that a very slight convexity is better for a road than a greater; that roads in wet situations often require underdraining; and that the gravel near London is too often used without being sufficiently cleaned. Mr Horne's horses generally wear out in about three years. The "light" coaches, with their loads, generally weigh about two tons and a half; the coach one, the passengers one, and the luggage a half. The Uxbridge road, he says, is generally heavy, because it lies lower than the neighbouring land, and is not sufficiently drained. Mr Eames reports that the Guildford road is so much improved by the introduction of flints instead of gravel, that sixteen miles are as easily performed on it by his horses as twelve were before the alteration. Mr Farey explains the principle upon which some of the roads about London are watered in winter; it is in order to soften the tenacious mud that is formed upon the surface, to prevent its adhering to the carriage-wheels, and to enable it to be scraped off with ease. He says that about Whitechapel it has been found very advantageous for the heavy traffic to have the middle of the road paved; and he thinks that two lines of pavement, one on each side, would be preferable to a single one, in order that the waggoners might walk at the sides of the road, leaving the middle for lighter carriages. He would have a road fifty-five feet wide, elevated about twelve inches in the middle. Broad wheels, he thinks, are seldom so flat as to bear on their whole surface at once, being commonly rather conoidal than conical; so that they differ less in their effect from narrower wheels than is commonly supposed. Mr Walker adheres to the old opinion, that in soft soils a road ought to be founded on bushes or "bavins;" that is, where they can be expected to remain always wet, so as not to be liable to a very speedy decay. He observes, that if a road does not possess some considerable convexity at first, it will wear concave, and collect mud; the elevation, he thinks, should be about one thirtieth of the breadth. Mr Telford informs the committee (p. 168) that the declivity of the Welsh roads was formerly in many places one inch in ten; and in some one in eight, and even one in six; but that the modern road scarcely ever rises above an inch in thirty; and that the utmost ascent in the whole line is one in seventeen for about two hundred yards. With respect to the weight of the stones, he agrees with Mr Macadam, that they ought not to exceed six or eight ounces; and that gravel is best cleaned by riddling it repeatedly, and leaving it to dry in the intervals.

SECT. III.—*Of the Roads of different Ages and Countries.*

The Romans appear to have been beyond comparison the greatest road-makers of the ancient or the modern world. The story told by Montaigne (iii. vi. p. 206) of a road in Peru, from Quito to Cuzco, 300 leagues long and twenty-five paces broad, made of stones ten feet square, with a running stream and a row of trees on each side, seems to have been considerably exaggerated; and it is not very clear whether the stones he mentions were used for the road or for the houses of entertainment built at intervals by its side; nor have the "rocks cut through" and "mountains levelled" been very particularly noticed by more recent travellers in that country. In Italy only, the Romans are said to have made more than 14,000 miles of road, which was generally executed with great care and labour; and many of their roads still remain as the foundation of the most favourite routes of Italian travellers. The more than Roman despot of modern times was as much a Roman in his road-making as in the selfish character of his general policy; and in proportion to the duration of his dynasty, he performed more than all the Appii and Flaminii of antiquity. Whatever his merits may have been, the beneficial effects of his measures remain; and those who have profited by his improvements have no right to criticise his motives with too great severity.

Of the great roads diverging from the gates of ancient Rome, about twelve have been enumerated by antiquaries, and twelve more branched off from these at a small distance from the city; eighteen others commenced in different parts of Italy, and in the whole there are at least fifty, which have been distinguished by appropriate names, without including the military roads through the distant provinces; such, for example, as in England were distinguished by the name of streets, of which many traces yet remain in different parts of the country.

Directly to the sea the Romans travelled by the Ostian road; along its shores to the north-west by the Aurelian, and to the south-east by the Appian. Next within the Aurelian was the Flaminian, then the Salarian, the Nomentanian, the Tiburtine, the Prænestine, the Lavican, and the Latin; and then the Appian, which was the most ancient of all, having been made as far as Capua, in the 442d year of the city, accompanied to a considerable distance by an aqueduct. The Aurelian road was made in the year 512; the Flaminian about 533.

I. The *Flaminian* road still affords the great northern approach to Rome by the Porta del Popolo; it led to Foligno, Ancona, and Rimini, and was continued by the *Emilian* to Bologna, and thence to Aquilegia, near Venice; the present mountain route from Bologna to Rome is still facilitated by the remains of the ancient structures. Besides the Emilian road, the Flaminian was also connected with the *Cassian*, leading to Modena; the *Claudian*, to Arezzo, Florence, and Lucca: there were also six other branches of less note, each named after its founder.

II. III. The *Salarian* and the *Nomentanian* roads lay to the east of the Flaminian; the former, from the Porta Salara, led through the country of the Sabines by Rieti to Hadria; the latter, from the Porta Sant' Agnese, went north-eastwards to Nomentum.

IV. The *Tiburtine* road led from the Porta Tiburtina, now San Lorenzo, to Tivoli, with a branch on the right called the Gabian. The large blocks which were employed to form this road, near the town of Tivoli, in ascending from the river, are still in their ancient places; they are accurately fitted together, and present a surface sufficiently smooth, after having been in use for about two thousand years.

V. VI. VII. The three next in order all met at Anagnia, twenty-four miles beyond Præneste or Palestrina. The *Prænestine*, from the Esquiline gate, now called Porta Maggiore, on account of the magnitude of the ruins of the aqueduct of Clodius, with which it is incorporated, led by Aquinum to Præneste; the *Lavican* led from the same gate, more to the right, by way of Beneventum; and the *Latin* road, from the Porta Latina, went first to Compitum, and from Anagnia proceeded to join the Appian near Capua.

VIII. The *Appian* road is as well known from the minute description of Horace's progress in his journey to Brundusium, as from the eagerness with which a modern traveller reckons the stages that he has completed, on his way to Naples, without a visit from the banditti that infest it. The original extent of this road, from the Colosseum to Capua, was 142 Roman miles; and it was continued 238 miles further to Brundusium by Julius Cæsar. It was constructed with large stones, or rather rocks, joined together with great care; and it is said to have had a foot-pavement two feet wide on each side, besides the agger, or principal mass of stones in the middle, and the two marginal parts, which were probably unpaved.

IX. The *Ostian* road led from the Porta di San Paolo, near the Tiber, in a straight line to the mouth of that river.

X. The *Aurelian*, from the Porta Aurelia, a gate which was near the Moles Adriani, or Castle of Sant' Angelo, led by Laurentum to Centumcellæ or Civita Vecchia, to Genoa, and thence by Susa, across the Montcenis, as far as Arles in Provence. This seems to have been the oldest passage into the Gauls; it was improved by Pompey the Great under the name of the Strata Romana. Several other passages over the Alps are also particularized in the *Itinerary* of Antonine on the roads from Milan to Arles; from Milan to Vienne in Dauphiné, either by the Grecian or by the Cottian Alps, the former north, the latter south of Montcenis; from Milan to Strasburg; and from Milan to Mentz.

XI. XII. The *Triumphal* road began from the Capitol, and went over the Tiber into the country beyond the present site of the Vatican. We may consider as the last of the twelve great roads, originating from Rome, the *Collatine*, leading due north from the Porta Pinciana on the Monte Pincio.

Among the less remarkable roads about the metropolis of the ancient world were also the Campanian, the new and the old Valerian, both leading by Tivoli to the Adriatic; the Tusculan, the Alban, the Ardeatine, on the right of the Appian; the Laurentine, a little more to the right, Pliny's villa being mentioned as accessible from either of these last; the Portuensis, from the Porta Portuese Trasteverina, leading to Ostia; and the Aurelia Nova, beginning from the Porta Janiculi, now Porta San Pancrazio, and leading towards Civita Vecchia.

Whether on the foundations of the ancient roads, or in any new lines that have been prepared in modern times by the magnificence of the pontiffs or of the princes, the great roads of Italy are at present almost universally well made and well repaired. In Lombardy, indeed, and throughout the immense plain that extends from the Alps to the Apennines, they are quite as good, in summer at least, as those in England. The cross roads of Italy are, however, greatly neglected; for it is in fact almost exclusively in Great Britain that private and individual exertion supersedes the necessity of public munificence. The intercourse of Italy with the rest of Europe has been greatly facilitated by the improvements made in the two great passages over the Alps by the authority of Bonaparte. The more useful of these improvements are probably those which have been effected on the southern side of Montcenis, since they enable the traveller to pass with little danger or difficulty at all seasons of the year; the more magnificent are the works at the Simplon, which, however, are not completely secure from the danger of *avalanches*, whenever fresh snow is lying on the ground. The Apennine portion of the Aurelian road has also been greatly improved by some still more recent operations, so that carriages may now pass with comparative ease and safety from Lucca to Genoa; though, for one stage, near Sestri, it is not thought advisable for the travellers to retain their seats within them.

The general declivity of the new road over Montcenis is one inch in fifteen or twenty; and it is never greater in the steepest part, that is, in the fourth and fifth turns that wind up over Lanslebourg, than one in twelve.[1] The road over the Simplon was executed jointly by the French and Italians, under the government of Bonaparte, from 1801 to 1805. The greatest declivity is one inch in twenty-nine; so that an English stage coachman might trot his horses up almost the whole way. The longest gallery or tunnel is about 500 feet under ground.

The roads in France are generally rough in their original formation, and still rougher from want of care in repairing them, as the traveller feels to his cost in passing over the primitive mountains in the south of that country, where the roads are certainly very different from those which are made by Macadam across a bog; although some of the more recent French and Flemish pavements, as long as they remain unimpaired, are truly excellent; the new pavement between Cologne and Brussels, for example, is far more perfect than some of the unpaved parts of the continuation of the same line of road to Calais, although the civil post-masters are in the habit of congratulating their English guests on the "fine gravel road" they will have to pass over. In Germany they have few pavements; and the roads, except in sandy countries, are generally kept, or keep themselves, in good repair; that is, in the south and the west of Germany. Mr Cripps informs us, that the great roads in Sweden are beautiful; they are very slightly convex, and made of granite broken to the size of a walnut. The Irish roads, according to Mr Edgeworth, are generally better than the English; the Scotish, Macadam thinks worse, though the materials are better; but in many parts of Scotland the roads appear to be more than sufficiently good for the commerce of the country.

ROAN, in the manège. A *roan* horse is one of a bay, sorrel, or black colour, with gray or white spots interspersed very thick. When this party-coloured coat is accompanied with a black head and black extremities, he is called *a roan horse with a blackamoor's head;* and if the same mixture is predominant upon a deep sorrel, he is called *claret-roan.*

ROANNE, an arrondissement of the department of the Loire, in France, which extends over 628 square miles. It comprehends ten cantons, divided into 108 communes, with 124,871 inhabitants. The capital is the city of the same name on the left bank of the Loire, which is so far navigable. It is a well-built city, with broad streets, good houses, and fine quays on the bank of the stream, and contains 9910 inhabitants, who are employed in making linen, cotton, and woollen goods, buttons, gilt ware, and jewellery. It is a place of great transit commerce, from being the chief depôt between Paris and Lyons, where the goods produced in the southern provinces can be transmitted to the capital by means of rivers and canals.

ROANOAK, an island of North America, near the coast of North Carolina. Here the English first attempted to settle in 1585, but were obliged to leave it for want of provisions. Long. 75. 0. E. Lat. 35. 40. N.

ROANOAK, a river of North America, which rises in Virginia, runs through Carolina, and at length falls into the sea, where it forms a long narrow bay called Albemarle Sound.

ROBERT'S ISLES, two large islands in the Pacific Ocean, with several smaller islets in their neighbourhood, discovered by Lieutenant Hergest in 1792. Long. 219. 47. E. Lat. 7. 53. S.

ROBERTSON, WILLIAM, one of the greatest historians of modern times, was the son of the Rev. William Robertson, minister of Borthwick, in the county of Edinburgh, and of Eleanor, the daughter of David Pitcairne, Esq. of Dreghorn. He was descended from the Robertsons of Gladney, a branch of the family which for many generations has possessed the estate of Struan in Perthshire. He was born at Borthwick in the year 1721, and received his early education at Dalkeith school, under Mr Leslie, a classical teacher of much reputation. In 1733 his father became one of the ministers of Old Greyfriar's Church in Edinburgh, and towards the close of the same year, the son commenced his academical studies. He speedily distinguished himself as a young man of superior talents and attainments. He obtained his license in 1741, and in 1743 he was appointed minister of Gladsmuir in the county of Haddington. In 1758 he was translated to Lady Yester's parish in Edinburgh, and other preferments speedily followed. In 1759 he was appointed chaplain of Stirling Castle; in 1761, one of his Majesty's chaplains in ordinary; and in 1762 he was elected principal of the university. In 1764 the office of historiographer to the king for Scotland was revived in his favour, and was accompanied with a salary of two hundred pounds a year. The emoluments arising from this accumulation of offices far exceeded what any Presbyterian clergyman in Scotland had previously enjoyed. About the period of his translation to Edinburgh he was created D. D.

We find it difficult to ascertain at what period were first unfolded the great and singular talents which destined Dr Robertson to be one of the first writers that rescued this island from the reproach of not having any good historians. We are, however, assured, that before the publication of any of his literary performances, even from his first appearance in public life, his abilities had begun to attract the notice of observing men; and to his more intimate friends he discovered marks of such high-minded ambition, as, seconded by those abilities, could not have failed to carry him to the first honours of his profession, in whatever sphere he had been placed, and whatever opposition he might have had to encounter.

The first theatre that offered for the display of his talents was the General Assembly of the Church of Scotland. It is the annual meetings of this court that produce to view men who would otherwise remain in the deepest obscurity. There the humble pastor, whose lot has been cast in the remotest corner of the Highland wilds, feels himself, for a time, on a footing of equality with the first citizen in the kingdom: he can there dispute with him the prize of eloquence, the most flattering distinction to a liberal mind; a distinction which is naturally sought after with the greater eagerness in that assembly, as the simple establishment of the Church of Scotland has rendered it the only pre-eminence to which the greatest part of its members can ever hope to attain.

From the moment Dr Robertson first appeared in this assembly, he became the object of universal attention and applause. His speeches were marked with the same manly and persuasive eloquence that distinguishes his historical compositions; and it was observed by all, that while his young rivals in oratory contented themselves with opening a cause, or delivering a studied harangue, he showed equal ability to start objections or to reply; and that even his most unpremeditated effusions were not unadorned with those harmonious and seemingly measured periods which have been so much admired in his works of labour and reflection. He soon came to be considered as the ablest supporter of the cause which he chose to espouse, and was now the unrivalled leader of one of the great parties which have long divided the church of which he was a member. When we reflect upon this circumstance, and consider how much mankind are the same in every society, we shall be the less surprised to find in the literary works of Dr Robertson an acquaintance with the human heart, and a knowledge of the world, which we in vain look for in many other historians. The man who has spent his life in the difficult task of conducting the deliberations of a popular assembly, in regulating the passions, the interests, the prejudices, of a numerous faction, has advantages over the mere man of letters, which no ability, no study, no second-hand information, can ever compensate.

The first work which extended his reputation beyond the walls of the General Assembly was a sermon preached at Edinburgh in 1758 before the Society for Propagating Christian Knowledge, the subject of which was, "The State of the World at the Appearance of Jesus Christ." The ingenuity with which a multiplicity of detached circumstances are there collected, and shown to tend to one single point, afforded a fair promise of those peculiar powers which he so conspicuously displayed in his historical works. This sermon, which was immediately published, did great honour to the author; and it is probably to the reputation which he thus acquired, that we are to attribute the unanimity with which he was called to be one of the ministers of Edinburgh.

In 1759, he published, in two volumes quarto, " The History of Scotland during the reigns of Queen Mary, and of King James VI. till his accession to the Crown of England, with a Review of the Scots History previous to that period." This work, in its structure, is one of the most complete of all modern histories. It is not a dry jejune narrative of events, destitute of ornament; nor is it a mere frothy relation, all glow and colouring. The historian discovers sufficient powers of imagination to engage the reader's attention, with a due proportion of judgment to check the exuberance of fancy. The arrangement of his work is admirable, and his descriptions are animated. His style is copious, nervous, and correct. He has displayed consummate skill in rendering such passages of our history as are familiar to our recollection agreeable and entertaining. He has embellished old materials with all the elegance of modern dress. He has very judiciously avoided too circumstantial a detail of trite facts. His narratives are succinct and spirited; his reflections copious, frequent, and generally pertinent. His sentiments respecting the guilt of Mary have indeed been warmly controverted by Tytler, Stuart, and Whitaker; and, till the publication of Mr Laing's Dissertation on the same subject, the general opinion seemed to be that their victory was complete. Dr Robertson was no rancorous or malignant enemy of the unfortunate queen. While relating what he doubtless believed, he makes every possible allowance for Mary from the circumstances in which she was placed; and his history will be read with pleasure by candid men of all parties as long as the language in which it is composed shall continue to be understood.

In 1769, Dr Robertson published, in three volumes quarto, " The History of the Reign of the Emperor Charles V. with a View of the Progress of Society in Europe from the Subversion of the Roman Empire to the beginning of the sixteenth century." The vast and general importance of the period which this history comprises, together with the reputation which the historian had deservedly acquired, cooperated to raise such high expectations in the public, that no work perhaps was ever more impatiently expected, or perused with greater avidity. The first volume, which contains an able and eloquent view of the progress of society, is a very valuable part of the work; for it serves not only as a key to the pages that follow, but may be considered as a general introduction to the study of the history of that period, in which the several powers of Europe were formed into one great political system, in which each took a station, in which it long remained, with less alterations than could have been expected, after the shocks occasioned by so many internal revolutions and so many foreign wars. Of the history itself, it may be sufficient to observe, that it has secured to the author a place among the greatest historians of modern times. It is distinguished by elegance of expression, depth of discernment, and correctness of judgment. The characters are drawn with singular skill. They are not contrasted by a studied antithesis, but by an opposition which results from a very acute and penetrating insight into the real merits of each character, fairly deduced from the several circumstances of his conduct exemplified in the history. For this work the author received L.4500 sterling.

In 1779, Dr Robertson published " The History of America," in two volumes quarto. This celebrated work may with great propriety be considered as a sequel to the preceding history. From the close of the fifteenth century we date the most splendid era in the annals of modern times. Discoveries were then made, the influence of which descended to posterity; and events happened that gave a new direction to the spirit of nations. To the inhabitants of Europe, America was in every respect a new world. There the face of the earth changed its appearance. The plants and trees and animals were strange, and nature seemed no longer the same. A continent opened that appeared to have recently come from the hands of the Creator, and which showed lakes, rivers, and mountains on a grander scale, and the vegetable kingdom in greater magnificence, than in the other quarters of the globe, but the animal tribes in a state of degradation, few in number, degenerated in kind, imperfect, and unfinished. The human species in the earliest stage of its progress, vast and numerous nations in the rudest form of the savage state which philosophers have contemplated, and two great empires in the lowest degree of civilization which any records have transmitted to our review, presented to the philosophic eye at this period the most fruitful subject of speculation that was to be found in the annals of history. The discovery of the New World, moreover, was not only a curious spectacle to the philosopher, but, by the change which it effected, an interesting spectacle to the human race. When Columbus set sail for unknown lands, he little expected that he was to make a revolution in the system of human affairs, and to influence the future destiny of Europe. The importance and celebrity therefore of the subject had attracted the attention of philosophers and historians. Views and sketches of the New World had been given by able writers, and splendid portions of the American story had been adorned with all the beauties of eloquence. But previously to the appearance of Dr Robertson's history, no author had bestowed the mature and profound investigation which such a subject required, or had exhibited that complete narration and perfect whole which it is the province of the historian to transmit to posterity. And as the subject upon which the author entered was grand, his execution was masterly. The character of his former works was immediately discerned in this. They had been read with uncommon admiration. When the History of Scotland was first published, and the author altogether unknown, Lord Chesterfield pronounced it to be equal in eloquence and beauty to the production of Livy, the purest and most classical of all the Roman historians. His literary reputation was not confined to his own country: the testimony of Europe was soon added to the voice of Britain. It may indeed be mentioned, as the characteristic quality of the author's manner, that he possessed in no common degree that supported elevation which is suitable to compositions of the higher class; and in his History of America he displayed that happy union of strength and grace which becomes the majesty of the historic muse. In the fourth book of his first volume, which contains a description of America when first discovered, and a philosophical inquiry into the manners and policy of its ancient inhabitants, he displays moreover so much patient investigation and sound philosophy, abounds in such beautiful or interesting description, and exhibits such variety and copiousness of elegant writing, that future times will probably refer to it as that part of his works which gives the best idea of his genius, and is the most finished of all his productions.

In 1787 appeared a translation of Clavigero's History of Mexico; in which work the author hazarded various reflections, tending in several instances to impeach the credit of Dr Robertson's History of America. This attack induced the learned historian to revise his work, and to inquire into the truth of the charges brought against it by the historian of New Spain; and this he appears to have done with a becoming attention to the importance of the facts that are controverted, and to the common interests of truth. The result he published in 1788, under the title of "Additions and Corrections to the former Editions of Dr Robertson's History of America." In many of the disputed passages, he fully answered Clavigero and vindicated himself; in others he candidly submitted to correction, and thus gave additional value to his own work.

The literary labours of Dr Robertson appear to have been terminated in 1791, by the publication of "An Historical Disquisition concerning the Knowledge which the Ancients had of India, and the Progress of Trade with that country prior to the Discovery of the Passage to it by the Cape of Good Hope; with an Appendix, containing Observations on the Civil Polity, the Laws, and Judicial Proceedings, the Arts, the Sciences, and Religious Institutions of the Indians." The perusal of Major Rennell's Memoir, for illustrating his map of Hindustan, suggested to Robertson the design of examining more fully than he had done in his History of America, into the knowledge which the ancients had of India, and of considering what is certain, what is obscure, and what is fabulous, in their accounts of that remote country. Of his various performances, this is not that of which the design is the most extensive, or the execution the most elaborate; but in his historical disquisition we perceive the same patient assiduity in collecting his materials, the same discernment in arranging them, the same perspicuity of narrative, and the same power of illustration, which so eminently distinguish his other writings, and which have long rendered them the delight of the British reader at home, and an honour to British literature abroad.

His truly useful life was closed on the 11th of June 1793, at Grange-House near Edinburgh, after a lingering illness, which he endured with exemplary fortitude and resignation. He had attained the age of seventy-two. It may be justly observed of him, that no man lived more respected, or died more sincerely lamented. Indefatigable in his literary researches, and possessing from nature a sound and vigorous understanding, he acquired a store of useful knowledge, which afforded ample scope for the exertion of his extraordinary abilities, and raised him to the most distinguished eminence in the republic of letters. As a minister of the gospel, he was a faithful pastor, and justly merited the esteem and veneration of his flock. In a word, he may be pronounced to be one of the most perfect characters of the age; and his name will be a lasting honour to the island that gave him birth. His conversation was cheerful, entertaining, and instructive; his manners affable, pleasing, and endearing.

The account of his Life and Writings, published by Mr Dugald Stewart, is one of the noblest pieces of biography that any language can boast of. It was published in a separate form, and likewise accompanies the later editions of his works.

Dr Robertson left a widow and a numerous family in prosperous circumstances. In 1751 he had married Mary the daughter of Mr Nisbet, one of the ministers of Edinburgh, and this domestic union had been productive of much happiness. His eldest son, the late Lord Robertson, was for many years a judge of the Court of Session. Two of his sons belonged to the military profession. His eldest daughter was the wife of Mr Brydone the celebrated traveller, and the mother of the present Countess of Minto. Another daughter married John Russell, Esq. writer to the signet. Lord Brougham is the grandson of Dr Robertson's sister.

ROBERVALLIAN Lines, a name given to certain lines used for the transformation of figures, so called from Roberval, the inventor of them. These lines are the boundaries of lines infinitely extended in length, yet equal to other spaces which are terminated on all sides. It is observed by the Abbé Gallois, that the method of transforming figures which is explained at the end of Roberval's treatise of Indivisibles, was the same with that afterwards published by James Gregory in his *Geometria Universalis*, and also by Dr Barrow in his *Lectiones Geometricæ*; and that it appears from Torricelli's letter, that Roberval was the inventor of this method of transforming figures, by means of certain lines called by Torricelli, for that reason, *Robervallian lines.* The same author adds, that J. Gregory probably first learned this method at Padua in the year 1668; for the method was known in Italy in 1646, although the book was not published till 1692. David Gregory endeavoured to refute this account, in vindication of his uncle James. His answer appeared in the Philosophical Transactions for 1694, and Gallois rejoined in the Memoirs of the French Academy for 1703; so that it remains in a state of uncertainty to which of the two we are to ascribe the invention.

ROBIGUS and ROBIGO, a Roman god and goddess, who joined in the preservation of corn from *blight.* Their festival was kept on the 25th of April.

ROBINS, Benjamin, an ingenious mathematician, was born at Bath in 1707. His parents were Quakers of low condition, and consequently were unable to have him much instructed in human learning; but his own propensity to science having procured him a recommendation to Dr Pemberton at London, by his assistance, while he attained the sublimer parts of mathematical knowledge, he commenced teacher of the mathematics. But the business of teaching, which required confinement, not suiting his active disposition, he gradually declined it, and engaged in business that required more exercise. Hence he tried many laborious experiments in gunnery, from the persuasion that the resistance of the air has a much greater influence on swift projectiles than is generally imagined. Hence also he was led to consider the mechanic arts that depend on mathematical principles; as the construction of mills, the building of bridges, the draining of fens, the rendering of rivers navigable, and the making of harbours. Among other arts, fortification much engaged his attention; and he met with opportunities of perfecting himself by viewing the principal strong places of Flanders, in some tours which he made with persons of distinction.

Upon his return from one of these excursions, he found the learned amused with Dr Berkeley's work entitled "The Analyst," in which an attempt was made to explode the method of fluxions. Mr Robins was therefore advised to clear up this subject by giving a distinct account of Sir Isaac Newton's doctrines, in such a manner as to obviate all the objections that had been made, without naming them. Accordingly he published, in 1735, "A Discourse concerning the Nature and Certainty of Sir Isaac Newton's Method of Fluxions;" and, some exceptions being made to his manner of defending Newton, he afterwards wrote two or three additional discourses. In 1738, he defended the same great philosopher against an objection contained in a note at the end of Baxter's *Matho, sive Cosmotheoria puerilis*; and the following year printed Remarks on Euler's Treatise of Motion, on Dr Smith's System of Optics, and on Dr Jurin's Discourse of distinct and indistinct Vision, annexed to Smith's work. In the mean while, Mr Robins did not solely confine himself to mathematical subjects; for in 1739 he published, without his name, three pamphlets on political affairs. Two of them, relating to the convention and negociation with Spain, were so highly esteemed as to occasion his being employed in a very honourable post: on a committee being appointed to examine into the past conduct of Sir Robert Walpole, he was chosen their secretary.

In 1742, Mr Robins published a small treatise entitled

"New Principles of Gunnery," containing the result of many experiments; and a discourse being published in the Philosophical Transactions, in order to invalidate some of his opinions, he thought proper, in an account which he gave of his book in the same Transactions, to take notice of those experiments. In consequence of this discussion, several of his Dissertations on the Resistance of Air were read, and the experiments exhibited before the Royal Society, for which he was presented by that honourable body with a gold medal.

In 1748 appeared Lord Anson's Voyage round the World, which, though Mr Walter's name is in the title, has been generally thought to be the work of Robins. Walter, chaplain on board the Centurion, had brought it down to his departure from Macao for England, when he proposed to print the work by subscription. It was however, it is said, thought proper that an able judge should review and correct it, and Robins was appointed; when, upon examination, it was resolved that the whole should be written by Robins, and that Walter's papers should only serve as materials. Hence the introduction entire, and many dissertations in the body of the work, it is said, were composed by him, without receiving the least assistance from Walter's manuscript, which chiefly related to the wind and the weather, the currents, courses, bearings, distances, the qualities of the ground on which they anchored, and such particulars as generally fill up a sailor's account. No production of this kind ever met with a more favourable reception: four large impressions were sold within a twelvemonth; and it has been translated into most of the languages of Europe. The fifth edition, printed at London in 1749, was revised and corrected by Robins himself. In the corrigenda and addenda to the first volume of the Biographia Britannica, printed in the beginning of the fourth volume of that work, it is however stated that Robins was only consulted with respect to the disposition of the drawings, and that he had left England before the book was printed. Whether this be the fact, as it is asserted to be by the widow of Mr Walter, it is not for us to determine.

Robins was soon afterwards desired to compose an apology for the unfortunate affair at Prestonpans. It was prefixed as a preface to "The Report of the Proceedings of the Board of General Officers on their Examination into the conduct of Lieutenant-General Sir John Cope;" and this preface was esteemed a masterpiece in its kind. He afterwards, through the interest of Lord Anson, contributed to the improvements made in the Royal Observatory at Greenwich. Having thus established his reputation, he was offered the choice of two considerable employments; either to go to Paris as one of the commissaries for adjusting the limits of Acadia, or to be engineer-general to the East India Company. He chose the latter, and arrived in the East Indies in 1750; but the climate not agreeing with his constitution, he died there the year following.

ROBINSON, Sir Richard, Lord Rokeby and archbishop of Armagh, was immediately descended from the Robinsons of Rokeby in the north riding of the county of York, and was born in 1709. He was educated at Westminster school, from whence he was elected to Christ Church, Oxford, in 1726. In 1733 he took the degree of A. M., and in 1748 that of D. D. Dr Blackburne, archbishop of York, appointed him his chaplain, and collated him first to the rectory of Elton in the east riding of Yorkshire, and next to the prebend of Grindall in the cathedral of York. In 1751, he attended the duke of Dorset, lord-lieutenant of Ireland, to that kingdom, as his first chaplain, and the same year was promoted to the bishopric of Killala. A family connection with the earl of Holdernesse, secretary of state, with the earl of Sandwich and other noblemen related to him, opened the fairest prospects of attaining to the first dignity in the Irish church. Accordingly, in 1759 he was translated to the united sees of Leighlin and Ferns, and in 1761 to Kildare. The duke of Northumberland being appointed to the lieutenancy of Ireland in 1765, he was advanced to the primacy of Armagh, made lord-almoner, and vice-chancellor of the university of Dublin. When Lord Harcourt was lord-lieutenant of Ireland in 1777, the king was pleased, by privy seal at St James's, February 6th, and by patent at Dublin the 26th of the same month, to create him Baron Rokeby of Armagh, with remainder to Matthew Robinson of West Layton, Esq.; and in 1783 he was appointed prelate of the most illustrious order of St Patrick. On the death of the duke of Rutland, lord-lieutenant of Ireland, in 1787, he was nominated one of the lords-justices of that kingdom. Sir William Robinson, his brother, dying in 1785, the primate succeeded to the title of baronet. He was the survivor in the direct male line of the Robinsons of Rokeby, being the eighth in descent from William of Kendal. His grace died at Clifton near Bristol in the end of October 1794.

ROBISON, John, a distinguished professor of natural philosophy, born in 1739 at Boghall, in the parish of Baldernock and county of Stirling, was a younger son of John Robison, Esq. who had formerly been a merchant at Glasgow, and had retired to live in considerable affluence on his estate at Boghall, not far from that city.

He was of a family sufficiently respectable to enable his son at a subsequent period to prove himself, to the satisfaction of the court of St Petersburg, a *gentleman* born. As a younger brother, that son was originally intended for the church, and went at an early age, according to the custom of Scotland, in 1750, to enter as a student in the university of Glasgow, so that he was initiated almost in the rudiments of Grecian literature under the able instruction of Dr Moor, the well-known professor of Greek; and he acquired such a knowledge of the classical languages as served to constitute him a correct scholar through life. He pursued his studies with so much attention as to obtain the approbation of his teachers and the admiration of his contemporaries, who were delighted with the originality and ingenuity of his conversation, though he did not himself reflect with perfect satisfaction upon the degree of application which he had exerted in his academical education. He took the degree of Master of Arts in 1756, having studied mathematics under Dr Robert Simson, and moral philosophy under Dr Adam Smith. The example of so correct and rigid a follower of the ancient methods of demonstration as Dr Simson, must unquestionably have exercised considerable influence on his yet unformed taste in mathematics; but he seems to have had a natural preference, either from the constitution of his mind, or from some previously acquired habits of thinking, for the geometrical method; for we are informed that "he first attracted the regard of Dr Simson by owning his dislike of algebra, and by returning a neat geometrical solution of a problem which had been given out to the class in an algebraical form: with this mode of solution the professor was delighted, though the pupil candidly acknowledged that it had been adopted only because he could not solve the problem in the manner required of the class."

In the course of his studies, he had imbibed an insuperable aversion to the pursuit of his original objects in the church; not certainly from any want of religious feeling, or from a dislike to the kind of life that was intended for him, but probably from some difficulties that had occurred to him respecting particular points of doctrine or of practice. He was therefore compelled to provide himself with some other occupation; and he readily accepted the offer of some of his friends in 1758, to recommend him to Dr Blair, a prebendary of Westminster, who had formed a scheme for sending Prince Edward, the young duke of York, to complete his professional education at sea, in company with a son of Admiral Knowles; and Mr Robison was to have instructed his royal highness in mathematics and navigation. On his arrival in London, he was much disappointed to find that the expedition had never been seriously intended; and he readily accepted an engagement to attend young Knowles as a private tutor, when he went as a midshipman on board of the Neptune of ninety guns, with Admiral Saunders, who had the command of a force intended to co-operate with General Wolfe in the reduction of Quebec; and upon the appointment of his friend as a lieutenant on board of the Royal William, Robison was himself rated as a midshipman in that ship.

The fleet arrived on the coast of America in April 1759; in May they got up the river, and Mr Robison was one of a party of 100 seamen draughted from the Royal William into the admiral's ship, under the command of Lieutenant Knowles. In this capacity he had an opportunity of seeing considerable service, and of making some surveys of the river and of the neighbouring country; an employment for which he was perfectly qualified, both as a geometrician and a draughtsman. He also remarked the effect of the aurora borealis on the compass, which had been noticed by Mairan and Wargentin some years before, but which was then not commonly known. After the battle which was signalized by the victory and death of the gallant Wolfe, the Royal William sailed with his body to Europe, and arrived at Spithead in November. The next year she was sent to cruise off Cape Finisterre; but in six months she was obliged to return home, from having the greater part of the men disabled by the scurvy.

He used to consider the two years that he spent on board of the Royal William as the happiest of his life; and no inconsiderable part of his gratification was derived from the study of seamanship as he saw it practised under the auspices of Captain Hugh Pigot. He did not, however, acquire any firm attachment to the mode of life which he had temporarily adopted; he was rather disposed to resume his academical pursuits, and he had overcome his earlier objections to the ecclesiastical profession. He could not, however, refuse the kindly invitation of Admiral Knowles to come and live with him in the country, and to assist him in some important experiments which he was making upon mechanical and nautical subjects.

In the month of February 1762, Lieutenant Knowles was appointed to the Peregrine sloop, of twenty guns, and Mr Robison accompanied him with the hope of becoming a purser. He visited Lisbon and several other parts of Portugal; but he found a cruise in a small ship much less convenient and agreeable than in a large one, and, fortunately for himself and for mankind, he finally quitted the Peregrine and the naval service in June, and returned to live with Admiral Knowles, who soon after recommended him as a proper person to take charge of Harrison's timekeeper, which had been completed by the labour of thirty-five years, after many unsuccessful experiments, and which was now sent out by desire of the Board of Longitude to the West Indies, under the care of young Harrison and of Mr Robison. The rate of the chronometer was ascertained at Portsmouth the 6th November 1762, and it indicated at Port Royal, in Jamaica, a difference of time amounting to $5^h\ 2^m\ 47^s$, which is only four seconds less than the true longitude. After a few days the observers had a prompt opportunity of returning home by the Merlin sloop, which was sent to Europe with despatches. The voyage was most disastrous with respect to wind and weather, and at last the ship took fire; but she arrived safe at Portsmouth in March, and on the 2d of April the watch gave $11^h\ 58^m\ 6\frac{1}{2}^s$, instead of 12^h, for the time of mean noon, so that the error, after six months, was only $1^m\ 53\frac{1}{2}^s$, amounting to no more than about twenty miles of distance.

Mr Robison received, upon his return, the afflicting intelligence of the total loss of the Peregrine, which had foundered at sea with her commander and the whole of the ship's company. He was also greatly disappointed in the failure of some hopes which had been held out to him from the Admiralty and the Board of Longitude; though in fact there is little reason for the public to regret that he was not gratified with the pursership, which he claimed as the reward of his services. He was indeed afterwards actually made a purser by Lord Sandwich, in 1763; but he then declined accepting the appointment. His biographers very naturally complain of the neglect of those boards which ought to have recompensed him; but certainly the Board of Longitude had no power whatever, and probably not much influence, in the appointment of a purser; and, after all, the delay of a year or two was nothing very uncommon in the navy.

He had now no other resource than to return to Glasgow, and to resume his academical pursuits with renewed energy. It was from this time that he dated his serious application to his studies. He became extremely intimate with Dr Reid and Dr Alexander Wilson; and he had the advantage of being a witness of two of the greatest steps in the improvement of physical science that have been made in modern times, Dr Black's experimental theory of heat, and Mr Watt's invention of a new steam-engine. Dr Black was the first that determined the quantity of heat required for the conversion of ice into water: Mr Watt, who was settled as a mathematical instrument-maker at Glasgow, had been employed in repairing a working model of Newcomen's engine for one of the professors of the university; and it was the difficulty of supplying this model with steam that suggested to Mr Watt the eligibility of having a separate condenser, and that led him, in conjunction with Dr Black, to a knowledge of the quantity of heat consumed in evaporation.

Amid the enthusiasm which is always inspired by the progress of scientific discovery and of practical improvement, Mr Robison found every encouragement and every facility for the pursuit of his favourite objects. He was recommended by Dr Black, upon his removal to Edinburgh in 1766, as his successor in the lectureship of chemistry, though without the appointment of a professor. He took charge, also, of the education of Mr Macdowall of Garthland, and of Mr Charles Knowles, afterwards Sir Charles. Admiral Knowles was soon after recommended by the British government to the empress of Russia, in order to effect a reformation in her navy, having been employed on a similar service in Portugal almost fifty years before; he had always been a firm friend to Mr Robison, and now engaged him on this mission, with a salary of L.250 a year; and they proceeded together to St Petersburg in December 1770. Being hospitably entertained on their way by the prince bishop of Liege, whom they found to constitute, with his chapter and all his servants, a lodge of freemasons, Mr Robison was easily persuaded to become one of that fraternity: in a few days he was made an apprentice, and by degrees attained the rank of Scottish master, as he has himself related in his publication upon the subject. He continued nearly two years at St Petersburg, still acting in the capacity of private secretary to Sir Charles, who was appointed president of the Board of Admiralty, much to the advantage of the Russian navy, though his improvements were frequently retarded by the prejudices of the native officers. Mr Robison was then appointed inspector general of the corps of marine cadets at Cronstadt, with a double salary, and with the rank of lieutenant-colonel. His duty was to receive the report of about forty teachers and professors, respecting the studies of 400 young noblemen, who were their pupils, and to class them according to his judgment of their merits; but he had himself nothing to teach, nor could he have had much occasion for "lecturing fluently in the Russian language," though he was introduced by his friend Kutusoff to the Grand Duke Paul as a proficient in that language; but to the empress he was not personally known. At Petersburg he could have lived without regretting his country, in the society of such men as Euler and Alpinus, admired by the Russians, and beloved by the British; but Cronstadt in winter was deplorably melancholy; and in 1773 he was induced, without much difficulty, to make some little pecuniary sacrifice in accepting the professorship of natural philosophy at Edinburgh, which had become vacant by the death of Dr Russell, and to which he had been recommended by Dr Robertson, then principal of the university. His determination was not disapproved by the Russian government, who granted him a pension of about L.80 a year for life; but it was only paid as long as three or four young men, who had accompanied him as pupils, continued to reside at Edinburgh; some discontent having been expressed because he did not keep up a correspondence with the academy on the improvement of maritime education.

He arrived at Edinburgh in September 1774. He married soon afterwards, and continued to reside in that city for the remaining thirty years of his life, paying only an annual visit to his native place, where he possessed a part of the paternal estate; not being solicitous to extend it, although "he did not diminish it otherwise than as it had been diminished before," that is, in making provision for younger children. His predecessor had been very judicious and successful as a lecturer, though not a mathematician of the highest order: he had himself more practical knowledge and experience in mechanics, and was better acquainted with the foreign mathematicians, who had naturally fallen under his notice during his residence on the continent. His lectures were considered by most of his pupils as somewhat too difficult to be followed; a complaint which, if it did not depend on their own want of preparatory information, arose perhaps rather more from the hasty manner of his enunciation than from the abstruseness of his matter. "The singular facility of his own apprehension," says Professor Playfair, "made him judge too favourably of the same power in others. To understand his lectures completely was, on account of the rapidity and the uniform flow of his discourse, not a very easy task, even for men tolerably familiar with the subject. On this account his lectures were less popular than might have been expected from such a combination of talents as the author of them possessed." This inconvenience was increased "by the small number of experiments he introduced, and a view that he took of natural philosophy, which left but a very subordinate place for them to occupy. An experiment, he would very truly observe, does not establish a general proposition, and never can do more than prove a particular fact;" but he seems to have carried this principle to some little excess: it is, in fact, the *illustration*, and not the *proof*, of general principles that is the object of a public exhibition of experiments; and it is very doubtful whether Archimedes, or Newton, or Leibnitz, or Euler, would have been very successful as *showmen*. With respect, however, to "accuracy of definition, to clearness, brevity, and elegance of demonstration, and even to neatness and precision in experiments," Professor Robison was very successful; his course extended "to every branch of physics and of mixed mathematics," and entered so fully into the detail of each particular division of the subjects, that "a more perfect system of academical instruction is not easily to be imagined." Nothing, in short, was wanting, but so much previous knowledge of mathematics in his pupils as he thought he had a right to expect, though his expectations were too rarely fulfilled.

The Philosophical Society of Edinburgh had almost been suffered to sink into oblivion after the publication of the third volume of its Essays, in 1756. Professor Robison became a member of it soon after his return from Russia, and was chosen secretary of the new society upon its formation by royal charter in 1783, when it incorporated with itself the whole of the surviving members of the former society. In 1798 he received the compliment of a degree of Doctor of Laws from the university of New Jersey; and a similar honour was paid him at Glasgow the year after. In 1800 he was elected, as successor to Dr Black, on the list of the foreign members of the Royal Academy of Sciences of St Petersburg.

In 1785 he was attacked by a severe disorder, from which he was never afterwards wholly free, though it produced little inconvenience besides pain, with some depression of spirits, which was, however, attributed rather to the closeness of his application than to the immediate effect of the disease, which was a glandular induration. For many years he was obliged to obtain the assistance of substitutes in the delivery of his lectures; but towards the end of his life he was able again to perform the duties of the professorship in person. He continued his literary labours with little intermission, and was most happy in the care and attention of his wife and children, whose virtues he found the best alleviation of his sufferings. He took a slight cold, after giving a lecture, on the 28th of January 1805, and died on the 30th.

1. It was comparatively late in life that Professor Robison assumed the character of an author, having communicated to the Royal Society of Edinburgh, in 1786, a paper on the Determination of the Orbit and Motion of the Georgium Sidus, which was published in the Edinburgh Transactions, vol. i. He had observed the opposition of the planet with an equatorial telescope only, and he had computed the elements of its orbit with greater accuracy than any other astronomer had then done; although his suspicion of the effect of such a planet on the motions of Jupiter and Saturn has not been confirmed by later investigations, the irregularities of these planets, on the contrary, having been otherwise explained.

2. A second paper, published in the same collection, vol. ii. p. 82, relates to the Motion of Light, as affected by refracting or reflecting substances which are themselves in motion. The author corrects some errors of Boscovich, who had miscalculated the effect of a water-telescope; but he seems to agree with Dr Wilson in the suggestion of another experiment of a similar nature, which, to say the least, is wholly superfluous.

3. The most important, beyond all comparison, of Professor Robison's scientific publications, are the articles which he communicated from time to time to the third edition of the Encyclopædia Britannica, and to its Supplement. It was under the care of Mr Colin Macfarquhar that the first twelve volumes of that edition of this work were published;[1] and upon his death, in 1793, the task of continuing it was committed to Dr Gleig, to whom Professor Robison became a most essential co-operator, and from that time "the work ceased to be a mere compilation." The first of his contributions, according to Professor Playfair, was the article OPTICS, but it is probable he only revised and enlarged that article: it was followed by PHILOSOPHY, which he wrote jointly with Dr Gleig; by PHYSICS, PNEUMATICS, PRECESSION, PROJECTILES, PUMPS, RESISTANCE, RIVERS, ROOF, ROPE-MAKING, ROTATION, SEAMANSHIP, SIGNAL, SOUND, SPECIFIC GRAVITY, STATICS, STEAM, STEAM-ENGINE, STEELYARD, STRENGTH, TELESCOPE, TIDE, TRUMPET, VARIATION, and WATER-WORKS; and in the

---

[1] The third edition of the Encyclopædia Britannica consisted of eighteen volumes; the Supplement to it of two volumes.

Supplement, by Arch, Astronomy, Boscovich, Carpentry, Centre, Dynamics, Electricity, Impulsion, Involution, Machinery, Magnetism, Mechanics, Percussion, Pianoforte, Position, Temperament, Thunder, Trumpet, Tschirnhaus, and Watch-work. Notwithstanding some degree of prolixity and want of arrangement, which could scarcely be avoided in the preparation of original articles for such a mode of publication, the whole of them, taken together, undeniably exhibit a more complete view of the modern improvements of physical science than had ever before been in the possession of the British public; and display such a combination of acquired knowledge with original power of reasoning, as has fallen to the lot of a few only of the most favoured of mankind.

4. It is not altogether with so high approbation that his friends and his biographers have mentioned a work, of a nature rather political than philosophical, entitled Proofs of a Conspiracy against all the Religions and Governments of Europe, Edinb. 1797, 8vo; though it went through several editions. The principal part of the book consists of the history of the *Illuminati* and the German Union, whom he considers as having become the chief agents in a plot first formed by the freemasons, at the suggestion of some ex-jesuit, who proposed for their model the internal economy of the order which he had quitted; and whatever foundation this outline may have had in truth, there is no doubt that the manner in which Professor Robison has filled it up, betrays a degree of credulity extremely remarkable in a person used to calm reasoning and philosophical demonstration: for example, in the admission of a story told by an anonymous German author, that the minister Turgot was the protector of a society that met at Baron d'Holbach's, for the purpose of examining the brains of *living children*, in order to discover the principle of vitality. He does not accuse the English freemasons of having participated in the conspiracy; but he considers the continental lodges as having been universally implicated in it.

5. After the death of Dr Black, in 1799, he undertook to superintend the publication of his Lectures on Chemistry, which appeared in 1803, 2 vols. 4to. And this task, which was rather laborious than difficult, he executed with equal zeal and ability. He endeavoured to reduce to their just estimate the comparative pretensions of the French and British chemists, though he is somewhat puritanically severe in criticizing the literal meaning of the compliments paid to Black by Lavoisier, on which he founds a charge of insincerity.

6. His last publication was the first volume of a series which was to form a complete system, entitled Elements of Mechanical Philosophy, Edinb. 1804, 8vo. It comprehended only Dynamics and Astronomy, and it never became very popular: it was too difficult for the many, who wished for general and philosophical notions only, and not sufficiently precise and demonstrative for the few, who wanted practical and numerical results. In attempting to combine the separate merits of the *Exposition du Système du Monde*, and of the *Mécanique Céleste*, the author sacrificed both the popular simplicity of the former, and the mathematical perfection of the latter. A few inaccuracies, which ought not to escape the attention of the reader of the work, have been pointed out in the Imperial Review for March 1805; a journal long since discontinued.

7. The contents of the volume last mentioned, together with some manuscripts intended to have formed part of a second, and the greater part of the articles furnished by Professor Robison to the Encyclopædia, were collected into a System of Mechanical Philosophy, with Notes, by David Brewster, LL. D. Edinb. 1822, 4 vols. 8vo; a spirited bookseller in London having undertaken the risk of the publication. 1. The first volume begins with the articles Dynamics, Projectiles, Corpuscular Forces, Capillary Attraction, Boscovich's Theory, and Rotation, all as remodelled for the Elements; then follow Strength of Materials, Carpentry, Roof, Construction of Arches, Construction of Centres. 2. The article Steam-Engine is enriched with notes and an appendix by the late Mr Watt: the next is Machinery, then Resistance of Fluids, Rivers, Water-works, Pumps. 3. Astronomy, Telescope, Pneumatics. 4. Electricity, Magnetism, Variation, Temperament, Trumpet, Watch-work, and Seamanship. The notes are not numerous, and the editor's principal labour has been to retrench some passages that appeared to him superfluous when the papers were to stand as parts of such a collection.

"Although Dr Robison's name," says Dr Brewster in his preface, "cannot be associated with the great discoveries of the century which he adorned, yet the memory of his talents and his virtues will be long cherished by his country. Imbued with the genuine spirit of the philosophy which he taught, he was one of the warmest patrons of genius wherever it was found. His mind was nobly elevated above the mean jealousies of rival ambition, and his love of science and of justice was too ardent to allow him either to depreciate the labours of others, or to transfer them to himself. To these great qualities as a philosopher, Dr Robison added all the more estimable endowments of domestic and of social life. His friendship was at all times generous and sincere. His piety was ardent and unostentatious. His patriotism was of the most pure and exalted character; and, like the immortal Newton, whose memory he cherished with a peculiar reverence, he was pre-eminently entitled to the high distinction of a Christian, patriot, and philosopher." His person was handsome, and his physiognomy prepossessing; and he appears to have been endowed with an extraordinary combination of talents, even exclusively of those which were called into immediate activity in his professional pursuits; for he was a good linguist, an excellent draughtsman, and an accomplished musician. His conversation was always energetic and interesting, and sometimes even poetical; and his liberality of sentiment was only limited by his regard for what he considered as the best interests of mankind.

A short account of his life was published in 1802, by a contributor to the Philosophical Magazine, who, among other inaccuracies, thought himself at liberty to assert that he was an admirer of the algebraical form of representation, in preference to the geometrical. His friend Dr Gleig soon after stepped forward to correct these mistakes, in the Antijacobin Review for 1802, and his letter was copied into the Philosophical Magazine. He asserts, from his own knowledge, that even yet Professor Robison "delights much more in geometry than in any of the modes of algebra, assigning as the reason of his preference, that in the longest demonstration the geometrician has always clear and adequate ideas, which the most expert algebraist can very seldom have." It may perhaps be asserted, on the other hand, that the same reasoning would lead us always to employ actual multiplication or division, in preference to the use of logarithms or of a sliding rule; and that the whole of the magic of calculation depends on the abstraction of the results from the numerous and separately unimportant steps by which they are obtained; but the having once seen those steps clearly is certainly of great importance to the process of reasoning, even when the memory no longer retains them; and no mathematician of correct taste can study the ancient geometricians without admiring the elegance and precision of their method, even amidst the pedantry which too frequently envelopes their expressions, and without being grateful for their punctuality in collecting their results into the very convenient form of distinct propositions, and in making such references from each proposition to the foundations on which it depends, as to enable him readily to trace back their steps to the most elementary principles; which is scarcely possible in any of the works of the most modern school of analysis. Professor Robison, however, seems rarely to have cultivated the higher mathematics for their own sake only, or any further than as they could be applied to the study of the phenomena of nature, or to the practice of the combinations of art: in fact, without some such limitation, there would be no track to guide us in the pathless regions of quantity and number, and their endless relations and functions. But besides the utility of the pure mathematics as a branch of early education, in exercising and fortifying the powers of the mind, it is impossible to foresee with certainty *how much* of mathematics may be wanted by the natural philosopher in any given investigation; and Professor Robison, as well as many others of his countrymen, would certainly have been the better for the possession of *a little more*, as the author of the criticisms in the Imperial Review has already had occasion to remark.

Philosophical Magazine, xiii.; Dr Gleig, in Antijacobin Magazine, xi. 1802; Stark's *Biographia Scotica;* Aikin's General Biography, viii. Lond. 1813, 4to; Playfair, in Edinb. Trans. vii. 1815, p. 495; Chalmers's Biographical Dictionary, xxv. Lond. 1816, 8vo. (L. L.)

ROBORANTS, in *Pharmacy*, medicines which strengthen the parts, and give new vigour to the constitution.

ROCAB, a small seaport of Hadramaut, in Arabia, on the Indian Ocean, thirty miles south-south-west of Sahar.

ROCHDALE, a market-town of the county of Lancaster, in the hundred of Salford, 197 miles from London and twelve from Manchester. It is situated in a fine valley on the river Roche, and is overlooked by the church, which stands on an eminence ascended by 118 steps. The hills around it abound in excellent coal. The chief occupation is the manufacture of flannels and other woollen goods. The parish is large, and contains twelve townships, two of which are in the west riding of Yorkshire. The population of the ten in Lancashire amounted in 1801 to 29,954, in 1811 to 45,227, in 1821 to 48,112, and in 1831 to 58,441; that of the Yorkshire part amounted in 1831 to 15,997. By the parliamentary reform bill this town has received the privilege of electing one member to the House of Commons, but it has no municipal corporation.

ROCHE-BERNARD, a town of France, in the department of Morbihan, and arrondissement of Vannes. It is situated on the river Vilaine, and contains 1380 inhabitants; but within the parish are 6670 persons, who are chiefly employed in making flaxen thread and linen goods.

ROCHECHOUART, an arrondissement of the department of the Upper Vienne, in France. It extends over 286 square miles, comprehends five cantons, divided into twenty-nine communes, and contains 48,818 inhabitants. The capital is the town of the same name, on the banks of the river Grenne. It contains 4123 inhabitants. Long. 0. 45. E. Lat. 45. 43. N.

ROCHEFORT, an arrondissement of the department of the Lower Charente, in France, which extends over 257 square miles. It comprises four cantons, divided into forty-two communes, and in 1836 contained 51,727 inhabitants. The capital is a city of the same name, about six miles from the mouth of the river Charente. The harbour is convenient and secure, and constantly contains many men of war. The wharfs are very well contrived, and vessels can take in or discharge the guns and other stores with great facility. It was first made a naval arsenal by Louis XIV. The city is surrounded with walls, and the harbour defended by strong forts. It is a regular, well-built city, with broad streets, containing five churches, a naval hospital, a school of navigation, and fine docks. There were, in 1836, 15,441 inhabitants, besides a garrison in the handsome barracks. There are establishments for making china, for refining sugar, and manufactories of ropes, cables, and sailcloth. Long. 0. 2. 54. W. Lat. 45. 16. 10. N.

ROCHEFOUCAULT, FRANCIS DUKE DE LA, prince of Marsillac, governor of Poitou, was born in 1603. He was the son of Francis, the first duke of Rochefoucault, and was distinguished equally by his courage and his wit. These shining qualities endeared him to all the nobility at court, who were ambitious of decorating themselves at once with the laurels of Mars and of Apollo. He wrote two excellent works; the one a book of Maxims, which, Voltaire says, has contributed more than any thing else to form the taste of the French nation; and the other, Memoirs of the Regency of Queen Anne of Austria. It was partly at the instigation of the beautiful duchess de Longueville, to whom he had long been attached, that the duke de Rochefoucault engaged in the civil wars, in which he signalized himself, particularly at the battle of St Antoine. After the civil wars were ended, he thought of nothing but enjoying the calm pleasures of friendship and literature. His house became the rendezvous of every person of genius in Paris and Versailles. Racine, Boileau, and Savigné, found in his conversation charms which they sought for in vain elsewhere. He was not, however, with all his elegance and genius, a member of the French Academy. The necessity of making a public speech on the day of his reception was the only cause that he did not claim admittance. This nobleman, with all the courage he had displayed upon various critical occasions, and with his superiority of birth and understanding over the common run of men, did not think himself capable of facing an audience to utter only four lines in public, without being out of countenance. He died at Paris in 1680, aged sixty-eight, leaving behind him a character which has been variously drawn by those who during his life were proud of his friendship.

ROCHELLE, an arrondissement of the department of the Lower Charente, in France, extending over 282 square miles. It comprehends seven cantons, divided into fifty-five communes, and in 1836 contained 78,797 inhabitants. The capital is the city of the same name, the seat of the departmental government and of the courts of law. It is on the sea-shore, is strongly fortified, and has a convenient and secure harbour defended by two forts. It is the seat of a bishop, has a cathedral, one Protestant and five Catholic churches, and in the year 1836 had 14,857 inhabitants, who are traders in wine, brandy, salt, and other domestic products, and in all kinds of colonial articles. It is celebrated for its long siege when held by the Protestants in 1628, which was continued for thirteen months, and was attended with dreadful sufferings. Long. 1. 14. 17. W. Lat. 46. 9. 33. N.

ROCHESTER, an ancient city in the county of Kent, thirty miles from London. It is commonly supposed to have been founded by the ancient Britons. In the time of the Romans it was one of their military stations, but did not attain any great celebrity until more than a century after the arrival of the Saxons, who in the reign of King Ethelbert, constituted it the seat of a bishop, and it was considered as a most important military station. By the Britons it was known under the name of *Dourbrys;* the Romans called it *Durobrivæ*, which the Saxons changed to *Roffcaster*, from which its present name has been derived. It is situated on the river Medway, a stream which, rising in the centre of Kent, becomes navigable at Maidstone, and increases, till, near Rochester, it is affected by the tides, which reach it from the Thames at the Nore. At Rochester is the first bridge over that fine stream. This bridge, built in the reign of King John, with the exception of the bridges in London, was long deemed superior to any other in the kingdom in height, strength, and elegance. It consists of eleven arches, three of which have been rebuilt, and the whole, by modern improvement, widened and beautified, and ornamented with balustrades, panels, and bold copings.

Rochester.

The largest arch is forty feet span, and the others thirty feet. The length is 560 feet, and the breadth twenty-four feet between the parapets. The river Medway is capable of receiving the largest vessels up to Rochester, but few are moored off the city, as Chatham, a mile lower down the river, is more convenient from the vicinity to the naval arsenal and the docks.

The ancient castle is an interesting object to all antiquaries. It stands on the south-west side of the city, on such an elevated spot that it can be seen at thirty miles distance. The streets of this city have no peculiar feature, except the narrowness and length; for in fact it consists chiefly of a single street, which is a continuation of Stroud towards the west and of Chatham towards the east, forming two rows of moderate houses, more than two miles from one end to the other, with a few short streets or lanes leading from them southward. With the exception of the cathedral, hereafter to be noticed, the town-hall is the most remarkable edifice: it was built in 1687. It is a handsome structure, with a spacious entrance-hall and staircase, the ceilings of both which are very curiously ornamented. Here the city business is transacted; and at the back part is the city jail. There is a free school, several charitable institutions, a custom-house, and a market-house. The diocese of Rochester is the smallest in the kingdom. It had a cathedral as early as the year 600, which was destroyed by Ethelbert, king of Mercia, in 676; and a few years after the city suffered much by the incursions of the Danes, but appears to have recovered some degree of respectability by the accession of King Athelstan, who appointed masters of the mint to superintend the coinage of money. The cathedral had been dilapidated at the Norman conquest; but Gundulph, who was removed from Normandy to fill the see, acquired money sufficient to rebuild the sacred edifice, though he died in 1094, before it was finished. Like most of the more ancient ecclesiastical erections, its plan is an improvement on the basilica of Rome, and it is built in the form of the cross of Christ, with a massive square tower at the point of intersection. The interior space to the west of the cross was the nave or body of the church, which represented the ship of St Peter: this part is more ancient than the nave of any other cathedral in the kingdom, and still retains most of the peculiar features of the style in which it was originally built, and is indeed one of the most interesting specimens of Norman architecture. The whole length of this nave is a hundred and fifty feet, and its breadth between the pillars thirty-three feet, and from one wall to the other seventy-five feet. The choir has an ascent of ten steps, and is a hundred and fifty-six feet in length. The western front of the cathedral, one of the most perfect specimens of Anglo-Norman architecture, was constructed with consummate ability at a period when the art had arrived at a high point of perfection. The centre door is formed of a semicircular arch, composed of rich mouldings, and is supported by four pillars, with capitals of wreathed foliage. Two of these pillars take the form of Caryatides, and present statues of King Henry I. and his queen Matilda, the daughter of Malcolm III. king of Scotland, being undoubtedly two of the most ancient statues remaining in England. This building presents many other objects of very high interest to the student and the admirer of ancient architecture. The cathedral contains but few monuments, and none with any striking peculiarity.

Rochester is not a place of much trade, except what arises from the great number of travellers passing through it in their way by Dover to and from the continent. The chief occupation is a considerable oyster-fishery, from beds in the river Medway, which river is under the concurrent jurisdiction of its own corporate body, and that of the lord-mayor and aldermen of London. The latter body make periodical visits of conservancy by water, and on such occasions the two corporations indulge together in sumptuous festivity. For municipal purposes, the city is divided into three wards, and is governed by a mayor, six aldermen, and seventeen councillors. The recorder and justices of the peace are appointed by the crown. The city returns two members to parliament. There is a well-supplied market on Fridays, and several annual fairs. The population amounted in 1821 to 8795, and in 1831 to 9811.

Rochford || Rocky Mountains.

ROCHFORD, a market-town of the county of Essex, in the hundred of the same name, thirty-nine miles from London. It is situated on a small river that empties itself into the Crouch. It has a good market on Thursday. The population amounted in 1801 to 1228, in 1811 to 1214, in 1821 to 1382, and in 1831 to 1256.

ROCKET, an artificial fire-work, consisting of a cylindrical case of paper, filled with a composition of certain combustible ingredients; which, being tied to a stick, mounts into the air, and then bursts. See PYROTECHNY.

ROCKY MOUNTAINS, a great mountain chain which traverses the western part of North America, extending from about latitude 70° north to Mexico, where it is continued by the Cordilleras of the Andes. These ranges are considered as forming part of one vast chain, which in South America, near the equator, attains its greatest elevation. At the Isthmus of Panama it is so low as nearly to disappear; but this is in conformity with the narrowness of the land in that quarter, and but for a short space. This slight interruption is not sufficient to entitle us to consider the continuity as broken, so that we have in the western hemisphere one great mountain range extending along both continents, from the Polar Sea on the north, to Cape Horn on the south, a distance of more than one hundred and twenty degrees of latitude, without including the windings. The eastern side of North America is traversed by a similar range of mountains called the Alleghanies, which stretch along in continued and parallel lines; but the extent, breadth, and height of the Rocky Mountains are much greater than those of the former. It is however supposed that the Rocky Mountains extend along the western part of the continent, at about the same distance from the Pacific Ocean that the Alleghanies on the eastern side extend from the Atlantic Ocean. Although but partially explored, the primitive character of the Rocky Mountains is clearly established. Their eastern sides are covered to the height of two hundred or three hundred feet, with a sandstone consisting of the ruins of the granitic rocks upon which it reposes, where disintegration was apparently effected by the gradual agency of an ancient ocean, once occupying the immense plain or basin now extending eastward from the base of these mountains to the chain of the Alleghanies. They have not however been sufficiently explored to admit our advancing any scientific details in regard to them. Many of the detached mountains and prominent peaks have not yet been either named, classified, or described. It does not appear that many of them rise above the region of perpetual refrigeration. But we have the concurrent testimony of Lewis and Clarke, as well as others, that in latitude 47° north, immense quantities of snow are on their summits, between the Missouri and Columbia, in the months of June and July. They are seen like a vast rampart rising from the grassy plains, stretching from north to south. Sometimes their aspect is that of continued ranges of a grayish colour, rising into the blue of the atmosphere, above the region of the clouds. A great number are black, ragged, and precipitous; and their bases are strewn with immense boulders and fragments of rock, detached by earthquakes and the elements. From this iron-bound and precipitous character they probably received the appellation of Rocky Mountains. Some of the peaks are supposed to be twelve or thirteen thousand feet in height; and the general range is considerably higher than any other in North America, with the exception of the

Cordilleras. It is not certainly known whether any of them are volcanic. Pumice stones are often seen floating on the Mississippi, and still oftener on the Missouri. These are generally of a reddish yellow, or flame colour, and are amongst the largest and finest specimens of this substance to be met with. Some assert that they proceed from hills of burning coal, but we never heard of hills of burning coal ever yielding such a product. They are entirely a volcanic production, and beyond doubt are either discharged from craters at present active, or are washed away by the mountain torrents, from places which were formerly the scene of such phenomena. Mica is also abundantly carried along by the waters which flow from the Rocky Mountains. The great rivers that are discharged from their eastern and western declivities wind among the mountains, the Arkansas on the east, and the Oregon or Columbia on the west, more than a hundred leagues before they issue into the plains. In following the beds of such streams, travellers pass through the range without much difficulty, so that the reports of the early travellers that they presented a high, continuous, and almost impassable barrier, are incorrect. Various leaders of expeditions have passed them at different points, and affirm that they found no such formidable and insurmountable barriers, the mention of which was wont to deter traders from attempting to cross from east to west or from west to east by this route. Following the river Platt, which is one of the principal southern branches of the Missouri, the traveller finds a road even to Lake Buenaventura, on the Pacific plains, that needs little labour to adapt it to the passage of horses and waggons. The acclivity is nowhere so great as to exceed an ascent of three degrees.

This vast range has been divided into the Rocky, Chepywan, and Masserne Mountains, on what ground is not exactly known. The ranges on the south, at the sources of the Arkansas, and running thence towards the Gulf of Mexico, are called the Masserne Mountains. A single peak of this ridge, seen as a landmark for immense distances over the subjacent plains, is called Mount Pike, a very appropriate name. It is described as of incomparable grandeur in appearance, and has been differently estimated at from seven to ten thousand feet in height. On the ridges of the Rocky Mountains, the Colorado of the Pacific, the Rio del Norte of Mexico, the Roche-jaune or Yellow-stone of the Missouri, and the Arkansas and Red River of the Mississippi, streams which have outlets at such immense distances apart, all have their origin. Many accounts have been given of the appearance of silver and other metals in the Rocky Mountains, but they have been too partially explored to entitle us to pronounce on the extent or value of the veins.

ROCROY, an arrondissement of France, in the department of the Ardennes, which extends over 295 square miles. It comprehends five cantons and sixty-eight communes, and the population in 1836 amounted to 46,156. The capital is a fortified city of the same name, situated in the midst of a wood. It contains 600 houses, and in 1836 had 3682 inhabitants. It is celebrated for its siege in 1643, when taken from the Spaniards by the great Condé. Long. 4. 26. 32. E. Lat. 49. 55. 36. N.

RODEZ, an arrondissement of the department of the Aveyron, in France, which extends over 797 square miles. It comprehends eleven cantons, divided into sixty-nine communes, and in 1836 contained 99,704 inhabitants. The capital is the city of the same name, and the seat of the departmental government and courts of law. It is the seat of a bishop, and has a fine cathedral, with a tower 250 feet high, which is a prominent object at more than forty miles distance. Rodez contains four churches, a lyceum, a hospital, and an exchange, with 9685 inhabitants, extensively employed as coppersmiths, and having manufactures of thin woollens, cutlery, and leather. Long. 2. 29. 5. E. Lat. 44. 21. N.

Rodney.

RODNEY, George Brydges, Lord Rodney, was born on the 19th of February 1718. He was the descendant of an ancient family, and was related to the duke of Chandos. His father Henry Rodney obtained, at the age of fourteen, a commission as cornet of horse; but having quitted the army after a short period of service, he settled at Walton-upon-Thames, and married Mary, eldest daughter and co-heiress of Sir Henry Newton, envoy extraordinary to the grand duke of Tuscany, and afterwards judge of the court of admiralty. Through the interest of the duke, who usually attended the king on his journeys to and from Hanover, Mr Rodney obtained the command of the royal yacht; and having on one of these occasions been asked what mark of favour he would wish the king to confer upon him, he requested that his majesty would stand sponsor for his son. Such a request was easily granted; and accordingly his second son was named after his royal and noble godfathers.

At a very early age he was sent to Harrow school; and having quitted it at the age of twelve, he received from the king a letter of service, the last ever granted, and went to sea. On the Newfoundland station he served for six years with Admiral Medley. On the 15th of February 1739 he was made lieutenant in the Dolphin, by Admiral Haddock, in the Mediterranean, and served successively in the Essex, Royal Sovereign, and Namur. Admiral Mathews having in 1742 appointed him to the Plymouth of sixty-four guns, he convoyed three hundred sail of the Lisbon trade through the midst of the French fleet, then cruising in the channel; and for his conduct on this occasion he received the warmest thanks of the merchants. In the rank of captain he was confirmed by the admiralty, and was appointed to the command of the Sheerness, in which he continued for eighteen months. He was then removed to the Ludlow Castle, of forty guns. In this ship he fought and took the great St Maloes privateer, of forty guns, and one hundred men above his own complement. From this period till December 1745, he was employed in various pieces of service, which afforded him no particular opportunities of obtaining distinction. Having been appointed to the Centurion, he for two years cruised in the North Sea; and on that station he commanded while the pretender was in Edinburgh, and until the arrival of Admiral Byng. He was now promoted to the command of the Eagle, of sixty-four guns; and in 1747 he was despatched in a small squadron for the purpose of intercepting the French fleet, homeward-bound from St Domingo. On the 20th of June they fell in with this fleet off Cape Ortegal. The French men-of-war deserted their convoy during the night, and no fewer than forty-eight merchantmen were captured. Rodney afterwards joined the squadron of Admiral Hawke, and bore a distinguished part in the action off Finisterre on the 14th of October in the same year. Near the close of this war, a small squadron, of which the Eagle was one, fell in with a Spanish fleet from the West Indies, consisting of twelve sail of the line with a rich convoy, and, notwithstanding their own inferiority, they took from them six sail of merchantmen.

Captain Rodney was appointed to the Rainbow in March 1748, and was soon afterwards sent as governor and commander-in-chief on the Newfoundland station. This was his first appearance with the rank of commodore. He had received particular instructions to discover, if possible, an island in the Western Ocean, said to be in lat. 49. N., about three hundred leagues from Britain. After cruising fourteen days to no purpose, he sailed for St John's, the seat of his government. In this station he continued till the month of October 1752, when he returned home to take his seat in parliament, having been elected for the borough of Saltash.

In May 1757 he sailed in the Dublin, of seventy-four guns, with Hawke's expedition for the bombardment of

Rochefort; and in February 1758, with Boscawen in the expedition against Louisbourg. On the 19th of May 1759 he was promoted to the rank of rear-admiral, and was immediately appointed to the command of a small squadron destined to bombard Havre de Grace. This service he performed in a very effectual manner; and having continued to keep the sea till the close of the ensuing year, he returned to Britain. In 1761 he was elected member of parliament for Penryn. On the 6th of October he hoisted his flag on board the Marlborough, having been appointed commander-in-chief at Barbadocs and the Leeward Islands, and to conduct the naval operations of the armament destined for the attack of Martinique. This island, together with St Lucia, was speedily reduced.

The admiral returned home on the 12th of August 1763. On the 21st of the preceding October he had been made vice-admiral of the blue. In 1764 he was created a baronet, and during the following year was appointed governor of Greenwich Hospital. In 1768 he was returned to parliament for Northampton. On the 18th of October 1770 he became vice-admiral of the white, and on the 24th of October 1771 vice-admiral of the red. During the latter year, on the 23d of January, he had been appointed commander-in-chief at Jamaica, and with this command was not permitted to retain the office of governor. Having returned to Britain, he struck his flag at Portsmouth on the 4th of September 1774.

Being inattentive, as many seamen are, to the rules of economy, his circumstances became so embarrassed that he was obliged to fly from his country, with very slight hopes of ever being able to return. He was in France when the ill-advised policy of that court prompted them to take a decided part with America against Great Britain; and it is said that some men in power, no strangers to the desperate state of Sir George's affairs, offered him a high command in the French navy, if he would carry arms against his own country. This offer he rejected with becoming indignation. Soon after this gallant behaviour, the duke de Chartres, afterwards the infamous Orleans, told Sir George that he was himself to have a command in the fleet to be opposed to that under the command of his countryman Keppel; and with an insulting air asked him what he thought would be the consequence of their meeting. "That my countryman will carry your highness with him to learn English," was the high-spirited reply. These statements do not perhaps rest on sufficient authority; but we learn from his own correspondence, that Maréchal Biron expressed his willingness to advance whatever sum he might require, even to the amount of two thousand pounds. Having accepted a loan of a thousand louis, he was in 1778 enabled to pay his bills in Paris, and to revisit his own country. He was speedily enabled to discharge this debt, and to make a satisfactory arrangement with his creditors.

On the 1st of October 1779, Rodney was appointed commander-in-chief of Barbadoes and the Leeward Islands. His first exploit after this appointment was on the 8th of January ensuing, when he took sixteen Spanish transports, together with seven ships and vessels of war, which had left St Sebastian's a week before. On the 16th of the same month he fell in with the Spanish fleet, consisting of eleven sail of the line, under the command of Don Juan de Langara; of which one was blown up during the engagement, five were taken and carried into Gibraltar, among which was the admiral's ship, and the rest were much shattered. In April the same year, he fell in with the French fleet under the command of Admiral Guichen, at Martinique, whom he compelled to fight, and whom he completely beat; though, from the shattered state of his own fleet, and the unwillingness of the enemy to risk another action, he took none of their ships. The successful efforts of the gallant admiral during the year 1780 were generally applauded through the nation. He received the thanks of both houses of parliament, and addresses of thanks from various parts of Great Britain, and the islands to which his victories were more particularly serviceable. In December the same year, he made an unsuccessful attempt, together with General Vaughan, on St Vincent's. In 1781, he continued his exertions, with much success, in defending the West India Islands; and, along with the above-named general, he conquered St Eustatius, on which occasion his conduct to the inhabitants has been much, though perhaps unjustly, censured. The island was certainly a nest of contraband traders. On the 12th of April 1782, he came to a close action with the French fleet under Count de Grasse; during which he sunk one ship and took five, of which the admiral's ship, the Ville de Paris, was one. On the 22d of May, the thanks of both houses of parliament were voted to the admiral, his officers, and seamen, for this brilliant and decisive victory. He was appointed vice-admiral of Great Britain, and was raised to the peerage by the title of Baron Rodney of Stoke in Somersetshire. The House of Commons voted him an annual pension of L.2000. In the year 1793 this pension was permanently settled on the title; and in 1806 a pension of L.1000 Irish was granted to his grandson for life. Having been superseded, very ungraciously, in his command, Lord Rodney once more steered a homeward course. He landed at Bristol on the 15th of September 1782, and next day proceeded to join his family at Purbrook near Portsmouth. He survived for ten years, having died on the 24th of May 1792, after he had completed the seventy-fourth year of his age.[1]

Lord Rodney had been twice married; first to the sister of the earl of Northampton, and next to the daughter of John Clies, Esq. With her he did not reside for several years before his death. He was succeeded in his title and estates by his son George, who married, in 1781, Martha, daughter of the Right Hon. Alderman Harley, by whom he had issue.

RODOSTO, a city of Turkey in Europe, in the province of Galipoli. It is situated on a small gulf of the same name, on the Sea of Marmora. It is strongly fortified, and well built, having, for a Turkish town, broad streets. It is the seat of a Greek archbishop, has five Greek and two Armenian churches, many mosques, baths, and caravanserais, 4000 houses, and 16,000 inhabitants. It is a place of considerable trade, chiefly in the products of the surrounding district. Long. 27. 20. 5. E. Lat. 40. 58. 34. N.

ROE, the seed or spawn of fish. See ICHTHYOLOGY.

ROEBUCK, JOHN, was born at Sheffield in Yorkshire in the year 1718. His father was a manufacturer of Sheffield goods, and by his ability and industry acquired a considerable fortune. He intended John to follow his own lucrative employment; but he was powerfully attached to other pursuits, and his father did not discourage his rising genius, but gave him a liberal education. After an elementary training, he was placed under the tuition of Dr Doddridge, by whose instructions he was rapidly improved in many branches of useful knowledge. Having completed his studies at the academy, he was afterwards sent to the university of Edinburgh, where he studied medicine, and chemistry, which then began to attract some attention in Scotland. He was much distinguished among his fellow students by his logical and metaphysical acuteness, and by great ingenuity in his arguments. Here he formed an acquaintance with Dr Robertson, Mr Hume, and other literary characters.

---

[1] The Life and Correspondence of the late Admiral Lord Rodney. By Major-General Mundy. Lond. 1830, 2 vols. 8vo. The author married Lord Rodney's youngest daughter.

Having completed his medical course at Edinburgh, he afterwards spent some time at the university of Leyden, where in 1743 he took the degree of M. D. He began to practise as a physician at Birmingham, a place which was then making rapid progress in arts, manufactures, and population, and where a favourable opening was presented to him by the death of an aged physician.

The extensive use of sulphuric acid in chemistry led many to various methods of obtaining it; and Dr Roebuck attempted to prepare it in such a manner as to reduce the price, for which purpose he substituted leaden vessels in the room of glass; and he had the good fortune to effect his benevolent design. Of this useful article he established a manufactory at Prestonpans in the year 1749, which was opposed by Dr Ward, but without success, as Roebuck's discovery did not come within Ward's patent. Dr Roebuck and his partner retained the advantages of their industry and ingenuity for a number of years, supplying the public with sulphuric acid at a much cheaper rate than had been formerly done. He found it expedient to relinquish his medical profession, and he resided in Scotland during the greater part of the year. He made some discoveries in the smelting of ironstone, greatly facilitating that process by using pit-coal instead of charcoal. He and his partner therefore projected a very extensive manufactory of iron, for which they soon procured a sufficient capital, as their friends had much confidence in their integrity and abilities. Dr Roebuck at length made choice of a spot on the banks of the river Carron, as the most advantageous situation for the establishment of their manufactory, abundance of ironstone, limestone, and coal, being found in its immediate vicinity. The preparations for this establishment were finished in the end of the year 1759; the first furnace was blown on the 1st of January 1760; and a second was soon afterwards erected.

These works turned the attention of Dr Roebuck to the state of coal in the neighbourhood, and to the means of procuring the extraordinary supplies which the iron-works might require. He therefore became lessee of the extensive coal and salt works at Borrowstownness, the property of the duke of Hamilton; in which he sunk, in the course of a few years, not only his own, and a considerable part of his wife's fortune, but the regular profits of his more successful works; and, what distressed him above every thing else, the great sums of money which he borrowed from his relations and friends, without the prospect of ever being able to repay them. This ruinous adventure cut off for ever the flattering prospects of an independent fortune which his family had once cherished; and he drew from his colliery only a moderate annual support, for which he was indebted to the indulgence of his creditors. Some years before his death, he was seized with a disorder that required a dangerous operation, and this he bore with his usual spirit and resolution. He was restored to a considerable share of his wonted health and activity; but its effects never wholly left him. He visited his works till within a few weeks of his decease, in order to give instructions to his clerks and overseers, and was confined to bed only a few days. He departed this life on the 17th of July 1794, retaining all his faculties, spirit, and good humour, to the last.

ROEMER, Olaus, a celebrated Danish mathematician and astronomer, was born at Arhusen in Jutland, in the year 1644, and was sent to the university of Copenhagen at the age of eighteen. By his assiduous application to the study of astronomy and mathematics, he became so eminent in those sciences, that Picard was astonished and delighted with him, when making observations in the north, by the order of Louis XIV. He was prevailed on to accompany Picard to France, and being presented to the king, he was chosen the dauphin's tutor in the study of mathematics. He was afterwards united with Picard and Cassini in making astronomical observations, and became a member of the Academy of Sciences in 1672. His discoveries acquired him great reputation during his ten years' residence at Paris; and he did not scruple to assert, that Picard and Cassini took the merit of many things which belonged exclusively to himself. Roemer was the first person who discovered the velocity with which light moves, by means of the eclipses of Jupiter's satellites, determining it to be about seven or eight minutes in coming from the sun to the earth. This opinion was opposed by many, but it was afterwards demonstrated in a most ingenious manner by Dr Bradley.

Christian V. king of Denmark, recalled Roemer to his native country in the year 1681, when he was appointed professor of astronomy at Copenhagen. He was also employed in the reformation of the coin and architecture of the country, in regulating the weights and measures, and in laying out the high roads throughout the kingdom; and his conduct was truly creditable to himself, and gave the greatest satisfaction to his royal employer. The consequence was that the king bestowed many dignities upon him, and among others appointed him chancellor of the exchequer. In fine, he was made councillor of state and burgomaster of Copenhagen under Frederic IV. who succeeded the king already mentioned. While Roemer was engaged in preparing to publish the result of his observations, he was cut off on the 19th of September 1710, when about sixty-six years of age. Horrebow, his disciple, made up this loss, by publishing in 4to, in 1753, when professor of astronomy at Copenhagen, various observations of Roemer, with his method of observing, under the title of *Basis Astronomiæ*. He had printed various astronomical observations and pieces in several volumes of the Memoirs of the Royal Academy of Sciences at Paris.

ROERMOND, or Ruremonde, one of the circles into which the province of Limburg is divided. It contains six cantons. The capital is the city of the same name, which stands on the left bank of the Maas, where the river Roer falls into it. It is fortified, but not strongly, and contains 4480 inhabitants, who make woollen cloths and carry on trade by the river. Long. 5. 53. 54. E. Lat. 51. 11. 48. N.

ROGA, in *Antiquity*, a present which the emperors made to the senators, magistrates, and even to the people; and the popes and patriarchs to their clergy. These rogæ were distributed by the emperors on the first day of the year, on their birthday, or on the *natalis dies* of the cities; and by the popes and patriarchs in passion-week. Roga is also used for the common pay of the soldiers.

ROGATION, Rogatio, in Roman jurisprudence, a demand made by the consuls or tribunes of the Roman people, when a law was proposed to be passed. *Rogatio* is also used for the decree itself made in consequence of the people's giving their assent to this demand; to distinguish it from a *senatus consultum*, or decree of the senate.

Rogation-Week, the week immediately succeeding Whitsunday; so called from the three feasts therein, viz. on Monday, Tuesday, and Wednesday.

ROGER de Hoveden, a learned man of the thirteenth century, was born in Yorkshire, most probably at the town of that name, now called *Howden*, some time in the reign of Henry I. After he had received the first parts of education in his native country, he studied the civil and canon laws, which were then become the most fashionable and lucrative branches of education. He was appointed domestic chaplain to Henry II. who employed him to transact several ecclesiastical affairs, in which he acquitted himself with honour. But his most meritorious work was, his Annals of England from A. D. 731, when Bede's Ecclesiastical History ends, to A. D. 1202. This work, which is one of the most voluminous of our ancient histories, is more valuable for the sincerity with which it is written, and the great variety of facts which it contains, than for the beauty of its style or the regularity of its arrangement.

ROGONATGUNGE, a town of Hindustan, in the province of Bengal, district of Pachete, 136 miles west-north-west from Calcutta. Long. 86. 20. E. Lat. 23. 15. N.

ROGONATPOOR, a town of Hindustan, province of Bengal, district of Pachete, 130 miles north-west from Calcutta. Long. 86. 44. E. Lat. 23. 32. N.

ROHAN, Henry Duke of, peer of France, and prince of Leon, was born at the Chateau de Blein, in Brittany, in 1579. Henry IV. under whose eye he gave distinguished proofs of his bravery at the siege of Amiens, when only sixteen years of age, loved him with as much affection as if he had been his own son. After the death of Henry, he became chief of the Calvinists in France; and was equally formidable for his genius as his sword. In defence of the civil and religious rights of his party, he maintained three wars against Louis XIII. The first, which terminated to the advantage of the Protestants, broke out when that prince wished to establish the Romish religion in Bearn; the second, because of the siege which Cardinal de Richelieu ordered to be laid to Rochelle; and the third, when that place was besieged a second time. The consequences of this war are sufficiently known: Rochelle surrendered, and the duke de Rohan, perceiving, that after the taking of this place, the majority of his party were endeavouring to make up matters with the court, succeeded in procuring for them a general peace in 1629, upon very honourable and advantageous terms. There is a very particular anecdote of him, extracted from the Memoirs of the Duchess of Rohan, Margaret of Bethune, daughter of the famous Sully. While the duke de Rohan was at Venice, a proposal was made to him from the Porte, that for 200,000 crowns, and an annual tribute of 20,000, the grand signior would give him the island of Cyprus, and fully invest him with the dignity and prerogatives of king. The duke was warmly inclined to comply with this proposal, and to settle in the island the Protestant families of France and Germany. He negociated this business at the Porte by means of the intervention of the patriarch Cyril, with whom he had much correspondence; but different circumstances, and in particular the death of the patriarch, contributed to break off the treaty. The republic of Venice chose Rohan for their commander in chief against the Imperialists; but Louis XIII. took him from the Venetians, and sent him ambassador into Switzerland, and into the Grisons. He wished to assist these people in bringing back La Valteline under their obedience, the revolt of which the Spaniards and Imperialists encouraged. Rohan, being declared general of the Grisons, after many victories drove the German and Spanish troops entirely from La Valteline in 1633. He again defeated the Spaniards in 1636, at the banks of the lake of Come. France, not thinking it proper to withdraw her troops, the Grisons rose up in arms, and the duke de Rohan, not satisfied with the conduct of the court, entered into a special treaty with them on the 28th of March 1637. This hero, fearing the resentment of Cardinal de Richelieu, retired to Geneva, with a view to join his friend the duke of Saxe-Weimar, who wished him to undertake the command of his army, then ready to engage the Imperialists near Rhinfeldt. Although he declined this honour, yet he took the command of the regiment of Nassau, with which he threw the enemy into confusion; but was himself wounded, 28th February 1638, and died of his wounds the 13th of April following, at the age of fifty-nine. He wrote several interesting performances: 1. The Interests of Princes, printed at Cologne in 1666, in 12mo; in which work he fully examines the public interests of all the princes of Europe. 2. The Perfect General, or an Abridgement of the Wars from Cæsar's Commentaries, in 12mo. Here he makes it appear, that a knowledge of the tactics of the ancients might be of much use to the moderns. 3. A Treatise on the Corruption of the Ancient Militia. 4. A Treatise on the Government of the thirteen Provinces. 5. Memoirs; the best edition of which is in two vols. 12mo. They contain the history of France from 1610 to 1629. 6. A Collection of some Political Discourses on State Affairs, from 1612 to 1629, 8vo, Paris, 1644, 1693, 1755; with the Memoirs and Letters of Henry Duke de Rohan relative to the War of La Valteline, three vols. 12mo, Geneva, 1757. This was the first edition which appeared of these curious memoirs: we owe it to the great attention and diligence of Baron de Zurlauben, who published them from different authentic manuscripts. He likewise ornamented this edition with geographical, historical, and genealogical notes, and a preface, which contains an abridged but highly interesting life of the duke de Rohan, author of the memoirs.

ROHAULT, James, a celebrated Cartesian philosopher, was the son of a merchant of Amiens, where he was born in 1620. He became well skilled in the mathematics, and taught them at Paris. He died at Paris in 1675. He wrote in French, 1. A Treatise on Natural Philosophy; 2. The Elements of Mathematics; 3. A Treatise on Mechanics, which is very curious; 4. Philosophical Conversations, and other works. His Physics have been translated into Latin by Dr Samuel Clarke, with notes, in which the Cartesian errors are corrected upon the Newtonian system.

ROHILCUND, in Sanscrit *Kuttair* or *Kuttaher*, an extensive and valuable district of Hindustan, situated between the rivers Ganges and Goggra, and between the twenty-eighth and thirtieth degrees of north latitude, and from seventy-eight to eighty east longitude. It is extremely well watered by the rivers Ganges and Ramgunga. The latter traverses the country throughout its whole extent, and joins the Ganges at Kanoge. Many smaller streams intersect the country, and contribute to its fertility, being distributed by means of canals and reservoirs. Water is also found by digging a foot under ground. With all these advantages, this country is remarkably fertile, and was extremely productive and well cultivated under its native sovereigns, though, when it was ceded to the British in 1801 by the nabob of Oude, it was in a state of desolation, owing to his tyranny and extortion. It abundantly produces grain of all sorts, sugar-cane, indigo, cotton, and tobacco. It also contains large forests of valuable timber, the wood of which is floated down the Dewah or Goggra, which issues from the Kemaon Mountains, and runs past the town of Pillibeet, and is thence embarked for Patna, Calcutta, and other large towns in the south. Its chief towns are Bareilly, Bissowly, Budavon, Moradabad, Owlah, Pillibeet, Rampore, Sumbul, with several others. In the early history of the Mogul empire, Rohilcund is celebrated as a very flourishing country, and of great political importance; and in many parts are still to be seen the remains of magnificent edifices, palaces, gardens, mosques, colleges, and mausoleums. In more recent times this district was occupied by a number of Afghans of the tribe of Roh or Rohillas. The founders of the dynasty were two brothers, named Shah Aalum, and Hussein Khan, who quitted Afghanistan about the year 1673, and settled in this country, where they pursued some inconsiderable employments under the Emperor Aurungzebe. Their descendants acquired possession of a considerable territory, which they ruled with prudence and moderation; and their territories were cultivated like a garden. A quarrel ensued between them and the nabob of Oude, to whose vengeance they were consigned by the British, who sent troops to aid in their extermination, under the understood condition that they were to share in the spoil. They were defeated by the British troops; and their country, given up to fire and oll- ‖ llin.

sword, was most cruelly wasted. Under Fyzoola Khan, one of the sons of Aly Mohammed, the country was in a most flourishing condition; and several of the Rohilla chiefs resided in each of the large towns, where they lived in a princely and hospitable manner, and gave every protection and encouragement to the farmers, so that the revenue amounted to a million sterling; but under the waste and ruin of this cruel invasion the revenue decreased in the course of twenty years to L.400,000, and the country went gradually to ruin. The country was transferred to the British in 1801, and is now governed by a civil establishment of officers stationed at Bareilly.

ROLL, or Roller, is a piece of wood, iron, brass, &c. of a cylindrical form, used in the construction of several machines, and in several works and manufactures.

ROLLAND, an island in the Southern Ocean, discovered by Kerguelen in 1773, about nine miles in circumference. Long. 68. 43. E. Lat. 48. 37. N.

ROLLI, Paul, an Italian poet, was born at Rome in 1687. He was the son of an architect, and a pupil of the celebrated Gravina, who inspired him with a taste for learning and poetry. An intelligent and learned English peer, having brought him to London, introduced him to the royal family as a master of the Tuscan language. Rolli remained in England till the death of Queen Caroline his protectress, and the patroness of literature in general. He returned to Italy in 1747, where he died in 1767, in the eightieth year of his age, leaving behind him a very curious collection in natural history, with a valuable and well-chosen library. His principal works first appeared in London in 1735 in 8vo. They consist of odes in blank verse, elegies, songs, and other poems, after the manner of Catullus. A collection of his epigrams was printed at Florence in 1776, in 8vo, to which is prefixed an account of his life by Fondini. What Martial said of his own collection may be said of this, "that there are few good, but many indifferent or bad pieces in it." Rolli, however, bore the character of one of the best Italian poets of his age. During his stay in London he procured editions of several authors of his own country. The principal of these were the Satires of Ariosto, the burlesque works of Berni, Varchi, &c. two vols. in 8vo; the Decameron of Boccace, 1727, in 4to and folio, in which he has faithfully copied the celebrated and valuable edition published by the Juntas in 1527; and, lastly, of the elegant Lucretia of Marchetti, which was printed at London in 1717, in 8vo, through the influence and attention of Rolli. This edition is beautiful; but the work is thought to be of a pernicious tendency. He likewise translated into Italian verse the Paradise Lost of Milton, printed at London in folio in 1735; and the Odes of Anacreon, London, 1739, in 8vo.

ROLLIN, Charles, a celebrated French writer, was the son of a cutler at Paris, and was born there on the 30th of January 1661. He studied at the College du Plessis, in which he obtained an exhibition through the interest of a Benedictine monk whom he had served at table, and who discovered in him some marks of genius. Here he acquired the regard of M. Gobinet, principal of the college, who had a particular esteem for him. After having studied humanity and philosophy, he applied to divinity three years at the Sorbonne; but he did not prosecute this study, and was satisfied with obtaining the tonsure. He afterwards became professor of rhetoric in his own college; and in 1688 succeeded Horsan, his master, as professor of eloquence in the Royal College. No man ever exercised the functions of it with greater eclat; he often made Latin orations to celebrate the memorable events of the times, and frequently accompanied them with poems, which were generally read and esteemed. In 1694 he was chosen rector of the university, and he continued in that office two years, which was then a mark of distinction. By virtue of his office, he spoke the annual panegyric upon Louis XIV. He made many very useful regulations in the university; and particularly revived the study of the Greek language, which was then much neglected. He substituted academical exercises in the place of tragedies; and introduced the practice which had been formerly observed, of causing the students to get by heart passages of Scripture. He was a man of indefatigable application, and trained innumerable persons, who did honour to the church, the state, and the army. The first president Portail was pleased one day to reproach Rollin in a jocular strain, as if he exceeded even himself in doing business; to whom Rollin replied, with that plainness and sincerity which was natural to him, "It becomes you well, sir, to reproach me with this; it is this habit of labour in me which has distinguished you in the place of advocate-general, which has raised you to that of first president; you owe the greatness of your fortune to me."

Rollin.

Upon the expiration of the rectorship, Cardinal Noailles engaged him to superintend the studies of his nephews, who were in the College of Laon; and in this office he was agreeably employed, when, in 1699, he was with great reluctance made coadjutor to the principal of the College of Beauvais. This college was then a kind of desert, inhabited by very few students, and without any regular discipline; but Rollin's great industry soon repeopled it, and raised it to that credit which it long retained. In this situation he continued till 1712; when the war between the Jesuits and the Jansenists drawing towards a crisis, he fell a sacrifice to the prevalence of the former. Father le Tellier, the king's confessor, a furious agent of the Jesuits, infused into his master prejudices against Rollin, whose connection with Cardinal de Noailles would alone have sufficed to make him a Jansenist; and on this account he lost his share in the principality of Beauvais. No man, however, could thus have suffered a smaller loss than Rollin, who had every thing left that was necessary to make him happy; retirement, books, and enough for his support. He now began to be employed upon Quinctilian; an author whom he justly valued, and could not without uneasiness see neglected. He retrenched in him whatever he thought rather curious than useful for the instruction of youth; he placed summaries or contents at the head of each chapter, and he accompanied the text with short and select notes. His edition appeared in 1715, in two vols. 12mo, with an elegant preface explaining his method and views.

In 1710, the university of Paris, willing to have a head suitable to the importance of their interests in a very critical conjuncture of affairs, chose Rollin again rector; but he was displaced in about two months by a lettre de cachet. The university had presented to the parliament a petition, in which it protested against taking any part in the adjustment of the late disputes; and their being congratulated in a public oration by Rollin on this step, occasioned the letter, which ordered them to choose a rector of more moderation. Whatever the university might suffer by the removal of Rollin, the public was probably a gainer; for he now applied himself to the composition of his Treatise on the Manner of Studying and Teaching the Belles Lettres, which was published in octavo, two volumes in 1726, and two more in 1728.

This work, though greatly deficient in order, and displaying neither depth nor philosophy, has been exceedingly successful; and its success encouraged its author to undertake another work of equal use and entertainment; his "Ancient History of the Egyptians, Carthaginians, Assyrians, Babylonians, Medes and Persians, Macedonians, and Greeks," which he finished in thirteen volumes 8vo, and published between 1730 and 1738. Voltaire, after having observed that Rollin was "the first member of the university of Paris who wrote French with dignity and correctness," says of this work, that "though the last volumes, which were written in too great a hurry, are not equal to the first, it is nevertheless the best compilation that had yet appeared in any language; because it is seldom that compilers are eloquent, and Rollin was remarkably so." This is perhaps saying too much. In this work there are indeed some passages very well handled; but they are only such as he had taken from the ancient authors, in doing justice to whom he was always very happy. The reader will easily discover in this work the same attachment to religion, the same desire for the public good, and the same love of virtue, which appear in that on the belles lettres. But it is to be lamented that his chronology is neither exact nor consistent; that he states facts inaccurately; that he has not sufficiently examined the exaggerations of ancient historians; that he often interrupts the most solemn narrations with mere trifles; and that his style is not uniform. Nothing can be more noble and more refined than his reflections; but they are strewed with too sparing a hand, and want that lively and laconic turn on account of which the historians of antiquity are read with so much pleasure. There is a visible negligence in his diction with regard to grammatical usage, and the choice of his expressions, which he does not at all times select with sufficient taste, although, on the whole, he writes well, and has preserved himself free from many of the faults of modern authors. While the last volumes of his Ancient History were printing, he published the first of his Roman History, which he lived to carry on, through the eighth and into part of the ninth, to the war against the Cimbri, about seventy years before the battle of Actium. Mr Crevier, the worthy disciple of Rollin, continued the history to the battle of Actium, which closes the tenth volume; and afterwards completed the original plan of Rollin in sixteen volumes 12mo, which was, to bring it down from the foundation of the city to the reign of Constantine the Great. This work had not so great success as his Ancient History. It is alternately diffuse and barren; and the greatest advantage of the work is, that there are several passages from Livy translated with great elegance into French. He also published a Latin translation of some of the theological writings relative to the disputes of the times in which he lived. Rollin was one of the most zealous adherents of the Abbé Paris; and before the enclosure of the cemetery of St Medard, this distinguished character might have been often seen praying at his tomb. This he confesses in his Letters. He published also Smaller Pieces, containing different Letters, Latin harangues, discourses, complimentary addresses, &c. Paris, 1771, two volumes 12mo. The collection is valuable for some good pieces which it contains, for the favourable opinion which it exhibits of solid probity, sound reason, and the zeal of the author for the progress of virtue and the preservation of taste. The Latin of Rollin is very correct, and much after the Ciceronian style, and embellished with most judicious thoughts and agreeable images. Full of the reading of the ancients, from which he brought quotations with as much propriety as plenty, he expressed himself with much spirit. His Latin poems are likewise entitled to commendation.

This excellent person died in 1741. He had been named by the king a member of the Academy of Inscriptions and Belles Lettres in 1701; but as he had not then brought the College of Beauvais into repute, and found he had more business upon his hands than was consistent with a decent attendance upon the functions of an academician, he begged the privileges of a veteran, which where honourably granted him. Nevertheless, he maintained his connections with the academy, attended their assemblies as often as he could, laid the plan of his Ancient History before them, and demanded an academician for his censor. Rollin was a man of an admirable composition; very ingenious, consummate in polite learning, of rigid morals, and eminently pious. His religion however carried him into the territories of superstition; and he wanted nothing but a mixture of philosophy in his nature to make him a very perfect character. Nothing could be more benign, more pacific, more sweet, more moderate, than Rollin's temper. He showed, it must be owned, some zeal for the cause of Jansenism; but in all other respects he was exceedingly moderate. The celebrated poet Rousseau conceived such a veneration for him, that he came out of banishment incognito to Paris, on purpose to visit him, and pay his respects to him. He looked upon his histories, not only as the best models of the historic kind, but as a complete system of politics and morals, and a most instructive school, in which princes as well as subjects might learn all their duties.

ROLLING, the motion by which a ship rocks from side to side like a cradle, by the agitation of the waves.

ROLLO, the conqueror of Normandy, was a Norwegian duke, banished from his country by Harold Harfager (who conquered Norway in 870) on account of the piracies he exercised. He first retired with his fleet among the islands of the Hebrides to the north-west of Scotland, whither the flower of the Norwegian nobility had fled for refuge ever since Harold had become master of the whole kingdom. He was there received with open arms by those warriors, who, eager for conquest and revenge, waited only for a chief to undertake some glorious enterprise. Rollo, placing himself at their head, and seeing his power formidable, sailed towards England, which had long been a field open on all sides to the violence of the northern nations. But the great Alfred had some years before established such order in his part of the island, that Rollo, after several fruitless attempts, despaired of forming there such a settlement as should make him amends for the loss of his own country. He pretended, therefore, to have had a supernatural dream, which promised him a glorious fortune in France, and which served at least to support the ardour of his followers. The weakness of the government in that kingdom, and the confusion in which it was involved, were still more persuasive reasons to insure them of success. Having therefore sailed up the Seine to Rouen, he immediately took that capital of the province, then called Neustria, and making it his magazine of arms, he advanced to Paris, to which he laid siege in form. This war at length ended in the entire cession of Neustria, which Charles the Simple was obliged to give up to Rollo and his Normans in order to purchase a peace. Rollo received it in perpetuity to himself and his posterity, as a feudal duchy dependent on the crown of France. A description of the interview between Charles and this new duke gives us a curious picture of the manners of these Normans; for the latter would not take the oath of fealty to his sovereign lord any other way than by placing his hands within those of the king; and absolutely refused to kiss his feet, as custom then required. It was with great difficulty that he was prevailed on to let one of his warriors perform this ceremony in his stead; but the officer to whom Rollo deputed this service suddenly raised the king's foot so high, that he overturned him on his back; a piece of rudeness which was only laughed at: to such a degree were the Normans feared, and Charles despised. Rollo was soon afterwards persuaded to embrace Christianity, and he was baptized with much ceremony by the archbishop of Rouen, in the cathedral of that city. As soon as he saw himself in full possession of Normandy, he exhibited such virtues as rendered the province happy, and deserved to make his former outrages forgotten. Religious, wise, and liberal, this captain of pirates became, after Alfred, the greatest and most humane prince of his time.

ROLLOCK, Robert, the first principal of the university of Edinburgh, was the son of David Rollock of Powis, in the vicinity of Stirling. He was born in the year 1555, and was taught the rudiments of the Latin tongue by a person then eminent in his profession. From school he was sent to the university of St Andrews, where his progress was so rapid, that he was made professor of philosophy soon after he took the degree of A. M.

The magistrates of Edinburgh having petitioned the king to found a university in that city, they obtained a charter, by which they were allowed all the privileges of a university, which was built in 1582, and Mr Rollock was chosen principal and professor of divinity. He was soon famous in the university on account of his lectures, and among his countrymen at large for his persuasive mode of preaching. In the year 1593, Rollock and others were appointed by parliament to confer with the popish lords; and in the following year he was one of those made choice of by the General Assembly to present his majesty with a paper entitled "The dangers which, through the impunity of excommunicated papists, traffickers with the Spaniards, and other enemies of the religion and state, are imminent to the true religion professed within this realm, his majesty's person, crown, and liberty of this our native country." Their zeal against popery was carried to excess, and they seem to have been of opinion, that it was incumbent on the civil magistrate to punish idolatry with death. In the year 1595, he was empowered, along with others, to visit the different universities in Scotland, with a view to inquire into the doctrine and practice of the different masters, the discipline adopted by them, and the state of their rents and living, which they were ordered to report to the next General Assembly.

He was chosen moderator of the General Assembly in the year 1597, at which period he was fortunate enough to obtain the redress of several glaring abuses. The greater part of his life was spent in conducting the affairs of the church, yet Spotswood assures us that he would rather have preferred retirement and study. Indeed the feebleness of his constitution was not equal to the hurry and bustle of public life, and it led him to prefer the retirement of study. He was very much affected with the stone, the pains of which he bore with the fortitude and resignation of a Christian. He died at Edinburgh on the last day of February 1598, in the forty-third year of his age. Short as his life was, he published many works, of which the following is a catalogue. A Commentary on the first book of Beza's Questions; on St Paul's Epistle to the Ephesians; on the prophet Daniel; a Logical Analysis of St Paul's Epistle to the Romans; some Questions and Answers concerning the Covenant of Grace and the Sacraments; a Treatise of Effectual Calling; a Commentary on the Epistles of Paul to the Thessalonians and Philemon; on fifteen select Psalms; on the Gospel of St John, with a Harmony of the four Evangelists upon the Death, Resurrection, and Ascension of Jesus Christ; certain Sermons on several places of St Paul's Epistles; a Commentary on the Epistle to the Colossians; a Logical Analysis of the Epistle to the Hebrews; of the Epistle to the Galatians; a Commentary upon the first two chapters of the first Epistle of St Peter; a Treatise of Justification, and another of Excommunication. All these, except the Sermons, were written in Latin. Of the pious and learned author, a more particular account may be found in a volume printed under the subsequent title: "De Vita et Morte Roberti Rollok, Academiæ Edinburgenæ Primarii, Narrationes, auctoribus Georgio Robertson et Henrico Charteris." Edinb. 1826, 4to. Robertson's biographical tract was originally published in 1599. That of Charteris was printed from a manuscript in the public library of the university.

ROLPAH, a town of Northern Hindustan, and capital of a district of the same name, in the province of Nepaul. It is a woody country, governed by a chief, who pays an annual tribute to the rajah of Nepaul. Long. 82. 5. E. Lat. 29. 22. N.

ROMA Isle, in the Eastern Seas, about forty miles in circumference. Long. 127. 30. E. Lat. 7. 35. N.

Roman Catholics.

ROMAN CATHOLICS. Under the head History (Ecclesiastical) will be found an account of the rise and progress of that religious system which, before the sixteenth century, held undisputed sway in what was called the Christian world. Under the head Reformation is given a history of the successful struggles made by several of the states of Europe to deliver themselves from priestly domination; and for a view of the theological tenets of the Roman Catholics, we may refer to the articles Pope, Popery, Purgatory, &c. It only remains that we shortly notice the extent to which the Roman Catholic faith prevails in the world at the present day, and the political state of its adherents in our own country.

There is no country where popery is the established religion, in the same sense in which the Churches of England and Scotland are the established religion of Britain. The Catholic clergy everywhere claim *independent*, if not supreme authority, and never form any political alliance with the state. In some countries, however, popery is not only the religion of the government, but also exclusively, or almost exclusively, of the people; and to that extent it may be called the *established religion* of the state. In others, the people are divided between the catholic and the protestant faith, and both are recognised by the government. The cruelty and oppression which have been perpetrated by religious zealots, ambitious priests, and crafty rulers, under the sacred name of religion, have given occasion to the infidel and the scoffer to cast on Christianity itself the reproach which is due only to fanaticism and bigotry. To this reproach both Catholic and Protestant are liable; but there can be no doubt, that in the efforts of the Church of Rome to maintain its ancient dominion over the human mind, it has been more unscrupulous in the use of persecution than the Protestant powers. Happily, however, the fierceness of persecution has now greatly abated in catholic countries; and, on the other hand, Catholics are tolerated in every protestant state.

France.

In France the *Charte* gives freedom of worship to all religions; but about 14-15ths of the people belong to the Catholic Church, the small remainder being Protestants.

Switzerland.

In Switzerland, outer Appenzell, almost the whole of Berne, Basel, Schaffhausen, Vaud, and Neufchatel, the greater part of Glarus, Grisons, Aargau, Thurgau, and Geneva, and the minority in Friburg, Soleure, and St. Gall, profess Calvinism. *Catholicism* is professed exclusively in Lucerne, Uri, Schwitz, Unterwald, Zug, inner Appenzell, Fessin, and Valais; by the majority in Friburg, Soleure, and St. Gall; and by the minority in the other cantons. About 12-20ths of the Swiss are Protestant; the remainder Catholics.

Belgium.

In Belgium all religions are freely professed; but catholicism is the religion of almost the entire nation.

Holland.

In Holland all religions are professed with equal freedom; but Calvinism is the religion of the state. The Catholics are comparatively few.

Germany.

In Germany catholicism and protestantism are so mixed, that it is scarcely possible to assign them definite limits, or approximate to their relative numbers. Protestantism, however, prevails mostly in the northern and south-western parts of the country; popery in the south-east, south, and west. Their numbers are not far from being equal.

Austrian Empire.

In the Austrian empire popery is the dominant religion, and professed by the great majority of the inhabitants.

Prussia.

In Prussia protestantism is the government religion; but the professors of all religions enjoy freedom of worship, and almost equal rights. Lutheranism is professed by the great majority in East Prussia, Brandenburg, Pomerania, and Saxony; popery in the Westphalian and Rhenish provinces, and the grand-duchy of Posen. Silesia and West Prussia are almost equally divided.

Denmark, Sweden, and Norway.

In Denmark, Sweden, and Norway, Lutheranism is the state religion, but all others are tolerated. The Catholics are few in number.

Russia.

Catholics abound in Russia, but mostly in the Polish provinces, where they are not only freely tolerated, but enjoy every political right in common with other subjects. Their number may amount to about 12,000,000, or 1-5th of the population of the empire.

Italy, Spain, and Portugal.

In Italy, Spain, and Portugal, popery is dominant and exclusive; but other religions, though not legally tolerated, are not now persecuted.

Turkey, Greece.

In Turkey and Greece popery is fully tolerated, but professed by few if by any of the natives.

America.

In America popery is the dominant religion of all the late Spanish and Portuguese colonies. In some of them no other religion is tolerated *by law*, but nobody is persecuted for professing any other. In the United States of North America, there are about 800,000 Catholics. In Lower Canada, they form the majority of the population.

Britain.

In Great Britain popery is now not merely tolerated, but Roman Catholics are admitted to equal, or nearly equal, political rights with Protestants.

In 1837, the total number of Catholics throughout the world, was reckoned by Adrien Balbi at 139,000,000, out of 737,000,000, which he considers to be the total population of the globe.

Before the passing of the various Roman Catholic Emancipation Acts, the Catholics in Great Britain and Ireland were subjected to a system of stringent penal laws. The laws in force against them, previously to the Act 18 Geo. III. cap. 60; and 31 Geo. III. cap. 32, may be divided into three classes: 1. Those respecting persons professing popery. 2. Those respecting popish recusants convict. 3. Those respecting popish priests.

I. Persons professing popery, besides the penalties for not attending their parish church, were disabled from taking their lands by either descent or purchase, after eighteen years of age, until they renounced their errors; were obliged at twenty-one to register their estates before acquired, and all future conveyances and wills relating to them; were incapable of presenting to any advowson, or granting to any other person any avoidance of the same; might not keep or teach any school under pain of perpetual imprisonment; and if they willingly heard or said mass, they forfeited for the one 100, and for the other 200 marks, and were to suffer a year's imprisonment. If any evil industry was used to rivet the errors of popery upon those who already professed it; if any person sent another abroad to be educated in popery, or to reside in any religious house for that purpose, or contributed to his maintenance when there, the sent, the sender, and the contributor, were disabled to sue in law or equity, to be executor or administrators to any person, or to bear any office in the realm, and forfeited all their goods and chattels, and likewise all their real estate for life. Where these errors were aggravated by apostacy or perversion, where a person was reconciled to the see of Rome, or procured others to be reconciled, the offence amounted to high treason.

II. Popish recusants convicted in a court of law of not attending the service of the Church of England, were subject to the following disabilities, penalties, and forfeitures, over and above those before mentioned. They were considered as persons excommunicated; they could hold no office or employment; if they kept arms in their houses, the same might be seized by the Justices of the Peace; they might not come within ten miles of London, under the penalty of L 100; could bring no action at law or suit in equity; were not allowed to travel above five miles from home, unless by licence, upon pain of forfeiting all their goods; and they might not come to court under the penalty of L.100. No marriage or burial of such recusant, or baptism of his child, should be had otherwise than by the ministers of the Church of England, under other severe penalties. A married woman, when recusant, forfeited two-thirds of her dower or jointure, and might not be executrix, or administratrix to her husband, or have any part of his goods; and during the coverture might be kept in prison, unless her husband redeemed her at the rate of L.10 a month, or the third part of all his lands. And, lastly, as a *femme couverte* (married woman) recusant might be imprisoned, so all others must, within three months after conviction, either submit, and renounce their errors, or, if required so to do by four justices, abjure and renounce the realm; and if they did not depart, or if they returned without the king's licence, they should be guilty of felony, without benefit of clergy. There was also an inferior kind of recusancy, (refusing to make the declaration against popery enjoined by Act 30 Car. II. cap. 2, when tendered by the proper magistrate,) which, if the party resided within ten miles of London, made him an absolute recusant convict; or, if at a greater distance, suspended him from having any seat in Parliament, keeping arms in his house, or any horse above the value of L.5.

III. Popish priests were placed in a still more slavish situation. For, by statute 11 and 12 Wil. III. c. 4, popish priests or bishops celebrating mass, and exercising any part of their functions in England, except in the houses of ambassadors, were liable to perpetual imprisonment. And by the statute 27 Eliz. c. 2, any popish priest born in the dominions of the crown of England, who should come hither from beyond sea, or should be in England without conforming, and taking the oaths, was guilty of high treason; and all persons harbouring him were guilty of felony without benefit of clergy.

The first amendment of these inhuman laws, which affix an everlasting stain on the British name, was effected by the statute 18 Geo. III. c. 60. With regard to such papists as should duly take the oath therein prescribed, of allegiance to his Majesty, abjuration of the Pretender, renunciation of the Pope's civil power, and abhorrence of the doctrines of destroying and not keeping faith with heretics, and deposing or murdering princes excommunicated by authority of the see of Rome, the statute 11 and 12 W. III. was repealed, so far as it disabled them from purchasing or inheriting, or authorized the apprehending or prosecuting of the popish clergy, or subjected them or any teachers of youth to perpetual imprisonment. By the statute 31 Geo. III. c. 32. all the restrictions and penalties above enumerated, were removed from those Catholics who were willing to comply with the requisitions of that statute, which were, that they must appear at some of the courts of Westminster, or at the quarter sessions held for the county, city, or place where they might reside, and make and subscribe a declaration that they professed the Roman Catholic religion, and also an oath exactly similar to that required by 18 Geo. III. c. 60. On this declaration and oath being duly made by any Roman Catholic, the officer of the court was authorised to grant him a certificate; and such officer was required yearly to transmit to the Privy Council lists of all persons who had thus qualified themselves within the year in his court. Roman Catholics thus qualified were not to be prosecuted under any statute for not repairing to a parish church, nor for attending or performing mass or other ceremonies of the Church of Rome. But no Roman Catholic minister was to officiate in any place of worship having a steeple and bell, or at any funeral in a churchyard, or was to wear the habits of his order, except in a place allowed by the statute, or in a private house where there should not be more than five persons besides the family. No person who had qualified was to be prosecuted for instructing youth, except in an endowed school, or in one of the English universities; or in the case of receiving into his school the child of any Protestant father; and no Roman Catholic was to keep a school until his or her name should be recorded as a teacher at the sessions.

But no religious order was to be established; and every endowment of a school or college by a Roman Catholic should still be superstitious and unlawful. And no person should thenceforth be summoned to take the oath of supremacy, and the declaration against transubstantiation. Nor should Roman Catholics who had qualified, be removable from London and Westminster; neither should any peer who had qualified be punishable for coming into the presence or palace of the king or queen. No papist whatever should be any longer obliged to register their names and estates, or to enrol their deeds and wills; and every Roman Catholic who had qualified, might be permitted to act as a barrister, attorney, or notary. Still, however, Roman Catholics could not sit in parliament, because every member of parliament was required to take the oath of supremacy, and repeat and subscribe the declaration against transubstantiation. Nor could they vote at elections for members of the House of Commons in Great Britain, because, before voting, they must have taken the oath of supremacy. But Roman Catholics in Ireland were permitted to vote at elections, though they could not sit in parliament.

Most of the remaining restrictions upon Roman Catholics were removed by the Act 10 Geo. IV. cap. 7, entitled, "An Act for the relief of his Majesty's Roman Catholic subjects," and passed 13th April 1829. By this act it was provided that all the preceding enactments (except as hereinafter excepted) should be repealed; and that from and after the commencement of the act, it should be lawful for any person professing the Roman Catholic religion, being a peer, or a member of the House of Commons, to sit and vote in either House, upon taking and subscribing the following oath, instead of the oath of supremacy, allegiance, and abjuration:

Oath t e taken Roma Cathol membe of Parliament

"I, A, B, do sincerely promise and swear, that I will be faithful, and bear true allegiance to his Majesty, King , and will defend him to the utmost of my power, against all conspiracies and attempts whatever, which shall be made against his person, crown, or dignity; and I will do my utmost endeavour to disclose and make known to his Majesty, his heirs and successors, all treasons and traitorous conspiracies which may be formed against him or them; and I do faithfully promise to maintain, support, and defend, to the utmost of my power, the succession of the crown, which succession, by an Act entitled, 'An Act for the further limitation of the Crown, and better securing the rights and liberties of the subject,' is, and stands limited to the Princess Sophia, Electress of Hanover, and the heirs of her body, being Protestants; hereby utterly renouncing and abjuring any obedience or allegiance unto any other person claiming or pretending a right to the crown of this realm: and I do further declare, that it is not an article of my faith, and that I do renounce, reject, and abjure the opinion, that princes excommunicated or deprived by the pope, or any other authority of the see of Rome, may be deposed or murdered by their subjects, or by any person whatsoever; and I do declare that I do not believe that the pope of Rome, or any other foreign prince, prelate, person, state, or potentate, hath or ought to have any temporal or civil jurisdiction, power, superiority, or pre-eminence, directly or indirectly, within this realm. I do swear that I will defend to the utmost of my power, the settlement of property within this realm, as established by the laws: and I do hereby disclaim, disavow, and solemnly abjure any intention to subvert the present church establishment, as settled by law within this realm; and I do solemnly swear that I will never exercise any privilege to which I am or may become entitled, to disturb or weaken the Protestant religion or Protestant government in the United Kingdom; and I do solemnly, in the presence of God, profess, testify, and declare, that I do make this declaration, and every part thereof, in the plain and ordinary sense of the words of this oath, without any evasion, equivocation, or mental reservation whatsoever. So help me God."

The other principal provisions of the Act are in substance as follows.

Roman Catholics, upon taking the oath above recited, shall be entitled to vote at elections for members of the House of Commons.

Roman Catholics may hold civil and military offices under his Majesty, except the office of Lord High Chancellor of Great Britain and Ireland, Lord Lieutenant of Ireland, or High Commissioner to the General Assembly of the Church of Scotland.

Roman Catholics to be eligible to become members of lay corporations, upon taking the oath hereby appointed, and such other oaths as may now by law be required of persons becoming members of such corporations; but such members are not to vote or join in the presentation or appointments to any ecclesiastical benefice.

No oath to be required from any Roman Catholic to enable him to hold any real or personal property, other than such as may be tendered to any other subjects; and the oath to be taken by Roman Catholic naval and military officers, to be taken at the same time, and in the same manner as the oaths now required by law from other subjects.

The Roman Catholic faith in Ireland is professed by more than four-fifths of the people, or, as ascertained in 1834, 6,427,712, out of a total population of 7,943,940; and in Great Britain, though the numbers are not precisely known, they are believed, according to the most moderate calculation, to fall little short of 1,000,000; by some they are even estimated at little short of 2,000,000; and according to the Catholic Directory, the number of Roman Catholic chapels in England and Wales, in 1839, amounted to 453; in Scotland, to 79; or, altogether in Great Britain, to 532. Of that number no less than 90 are in Lancashire alone, and 29 in Yorkshire; while Rutland and Huntingdon are the only counties of England where there is none. Besides numerous smaller seminaries, they possess ten colleges; viz. St. Edmund's, Old Hall Green, Ware, in Hertfordshire; Ushaw, Durham; St. Mary's, Birmingham; St. Peter's and St. Paul's, both at Prior Park, Bath; Stonyhurst, Lancashire; Ampleforth, York; St. Gregory's, Downside, Bath; German College, Broadway, Worcestershire; St. Mary's, at Blairs, on Deeside, Aberdeenshire; and a new college has been nearly finished at Sutton Coldfield, Lancashire. They already number eighteen nunneries and convents: Mecklegate bar, York; Hammersmith, Middlesex; Bishop's House, Winchester; Taunton Lodge, Somerset; New Hall, Chelmsford, Essex; Spettisbury House, Blandford; Stanbrook Hall, Worcester; Caverswall Castle, Staffordshire; Clare Lodge, Yorkshire; St. Mary's Priory, Leamington, Warwickshire; Ashton Hall, Staffordshire; Llanherne, South Cornwall; Carmel House, Darlington, Durham; Court House, Bridgewater, Somerset; Saleshouse, Westbury, Wiltshire; Hartbury Court, Gloucester; Presentation, Manchester; St. Margaret's, Edinburgh.

In Ireland the Roman Catholics have a regular hierarchy of archbishops, bishops, deans, &c., and have under them an establishment of upwards of 2000 parochial clergy. England is divided into four, and Scotland into three districts, each under the superintendence of a vicar apostolic, bearing the title of a bishop *in partibus ethnicorum*.

ROMANCE.

Romance.

Definition and origin of the word romance.

Dr. Johnson has defined Romance, in its primary sense, to be "a military fable of the middle ages; a tale of wild adventures in love and chivalry." But although this definition expresses correctly the ordinary idea of the word, it is not sufficiently comprehensive to answer our present purpose. A composition may be a legitimate romance, yet neither refer to love nor chivalry—to war nor to the middle ages. The "wild adventures" are almost the only absolutely essential ingredient in Johnson's definition. We would be rather inclined to describe a *Romance* as "a fictitious narrative in prose or verse; the interest of which turns upon marvellous and uncommon incidents;" being thus opposed to the kindred term *Novel*, which Johnson has described as "a smooth tale, generally of love;" but which we would rather define as "a fictitious narrative, differing from the romance, because the events are accommodated to the ordinary train of human events, and the modern state of society." Assuming these definitions, it is evident, from the nature of the distinction adopted, that there may exist compositions which it is difficult to assign precisely or exclusively to the one class or other; and which, in fact, partake of the nature of both. But the distinction will be found broad enough to answer all general and useful purposes.

The word Romance, in its original meaning, was far from corresponding with the definition now assigned. On the contrary, it signified merely one or other of the popular dialects of Europe, founded, as almost all these dialects were, upon the Roman tongue, that is, upon the Latin. The name of romance was indiscriminately given to the Italian, to the Spanish, even, in one remarkable instance at least,[1] to the English language. But it was especially applied to the compound language of France; in which the Gothic dialect of the Franks, the Celtic of the ancient Gauls, and the classical Latin, formed the ingredients. Thus Robert De Brunne:

> "All is calde geste Inglis,
> That en this language spoken is—
> Frankis speech is caled *Romance*.
> So sayis clerkis and men of France."

At a period so early as 1150, it plainly appears that the Romance language was distinguished from the Latin, and that translations were made from the one into the other; for an ancient romance on the subject of Alexander, quoted by Fauchet, says it was written by a learned clerk,

> "Qui *de Latin* la trest, et *en Roman* la mit."

The most noted romances of the middle ages were usually composed in the romance or French language, which was, in a peculiar degree, the speech of love and chivalry; and those which are written in English always affect to refer to some French original, which usually, at least, if not in all instances, must be supposed to have a real existence. Hence, the frequent recurrence of the phrase,

> "As in romance we read;"

Or,

> "Right as the romaunt us tells;"

and equivalent phrases, well known to all who have at any time perused such compositions. Thus, very naturally, though, undoubtedly by slow degrees, the very name of romaunt, or romance, came to be transferred from the language itself to that peculiar style of composition in which it was so much employed, and which so commonly referred to it. How early a transference so natural took place, we have no exact means of knowing; but the best authority assures us, that the word was used in its modern sense so early as the reign of Edward III. Chaucer, unable to sleep during the night, informs us, that, in order to pass the time,

> "Upon my bed I sate upright;
> And bade one rechin me a boke,
> A Romaunce, and it me took
> To read and drive the night away."

The book described as a romance contained, as we are informed,

> "———— Fables
> That clerkis had, in old time,
> And other poets, put in rhyme."

And the author tells us a little lower,

> "This book ne spake but of such things,
> Of Queens' lives and of Kings."

The volume proves to be no other than Ovid's *Metamorphoses;* and Chaucer, by applying to it the name of romance, sufficiently establishes that the word was, in his time, correctly employed under the modern acceptation.

Having thus accounted for the derivation of the word, our investigation divides itself into three principal branches, though of unequal extent. In the first of these we propose to inquire into the general history and origin of this peculiar species of composition, and particularly of romances relating to European chivalry, which necessarily form the most interesting object of our inquiry. In the second, we shall give some brief account of the history of the romance of chivalry in the different states of Europe. Thirdly, we propose to notice cursorily the various kinds of romantic composition by which the ancient romances of chivalry were followed and superseded, and with these notices to conclude the article.

Gener history roman

I. In the views taken by Hurd, Percy, and other older authorities, of the origin and history of romantic fiction, their attentions were so exclusively fixed upon the romance of chivalry alone, that they appear to have forgotten that, however interesting and peculiar, it formed only one species of a very numerous and extensive genus. The progress of romance, in fact, keeps pace with that of society, which cannot long exist, even in the simplest state, without exhibiting some specimens of this attractive style of composition. It is not meant by this assertion, that in early ages such narratives were invented, in the character of mere fictions, devised to beguile the leisure of those who had time enough to read and attend to them. On the contrary, romance and real history have the same common origin. It is the aim of the former to maintain as long as possible the mask of veracity; and indeed the traditional memorials of all earlier ages partake in such a varied and doubtful degree of the qualities essential to those opposite lines of composition, that they form a mixed class between them; and may be termed either romantic histories, or historical romances,

---

[1] This curious passage was detected by the industry of Ritson in *Giraldus Cambrensis*, "*Ab aquâ illa optima, quæ Scottice vocata est* Froth; *Brittanice*, Weird; Romane vero *Scotte-Wattre*." Here the various names assigned to the Frith of Forth are given in the Gaelic or Earse, the British or Welsh; and the phrase *Roman* is applied to the ordinary language of England. But it would be difficult to shew another instance of the English language being termed Roman or Romance.

e. according to the proportion in which their truth is debased by fiction, or their fiction mingled with truth.

A moment's glance at the origin of society will satisfy the reader why this can hardly be otherwise. The father of an isolated family, destined one day to rise into a tribe, and in further progress of time to expand into a nation, may, indeed, narrate to his descendants the circumstances which detached him from the society of his brethren, and drove him to form a solitary settlement in the wilderness, with no other deviation from truth, on the part of the narrator, than arises from the infidelity of memory, or the exaggerations of vanity. But when the tale of the patriarch is related by his children, and again by his descendants of the third and fourth generation, the facts it contains are apt to assume a very different aspect. The vanity of the tribe augments the simple annals from one cause; the love of the marvellous, so natural to the human mind, contributes its means of sophistication from another; while, sometimes, the king and the priest find their interest in casting a holy and sacred gloom and mystery over the early period in which their power arose. And thus altered and sophisticated from so many different motives, the real adventures of the founder of the tribe bear as little proportion to the legend recited among his children, as the famous hut of Loretto bears to the highly ornamented church with which superstition has surrounded and enchased it. Thus the definition which we have given of Romance as a fictitious narrative turning upon the marvellous or the supernatural, might, in a large sense, be said to embrace

> ——— quicquid Græcia mendax
> Audet in historia,

or, in fine, the mythological and fabulous history of all early nations.

It is also important to remark, that poetry, or rather verse, rhythm at least of some sort or other, is originally selected as the best vehicle for these traditional histories. Its principal recommendation is probably the greater facility with which metrical narratives are retained in the memory, a point of the last consequence, until the art of writing is generally introduced; since the construction of the verse itself forms an artificial association with the sense, the one of which seldom fails to recall the other to recollection. But the medium of verse, at first adopted merely to aid the memory, becomes soon valuable on account of its other qualities. The march or measure of the stanza is gratifying to the ear, and, like a natural strain of melody, can be restrained or accelerated, so as to correspond with the tone of feeling which the words convey; while the recurrence of the necessary measure, rhythm or rhyme, is perpetually gratifying the hearer by a sense of difficulty overcome. Verse being thus adopted as the vehicle of traditional history, there needs but the existence of a single man of genius, in order to carry the composition a step higher in the scale of literature than that of which we are treating. In proportion to the skill which he attains in his art, the fancy and ingenuity of the artist himself are excited; the simple narrative transmitted to him by ruder rhymers is increased in length; is decorated with the graces of language, amplified in detail, and rendered interesting by description; until the brief and barren original bears as little resemblance to the finished piece, as the *Iliad* of Homer to the evanescent traditions, out of which the blind bard wove his tale of Troy Divine. Hence, the opinion expressed by the ingenious Percy, and assented to by Ritson himself. When about to present to his readers an excellent analysis of the old romance of *Lybius Disconius*, and making several remarks on the artificial management of the story, the Bishop observes, that "if an epic poem may be defined a fable related by a poet to excite admiration and inspire virtue, by representing the action of some one hero favoured by Heaven, who executes a great design in spite of all the obstacles that oppose him, I know not why we should withhold the name of *epic poem* from the piece which I am about to analyse."[1]

Yet although this levelling proposition has been laid down by Percy, and assented to by Ritson (writers who have few opinions in common,) and although, upon so general a view of the subject, the *Iliad*, or even the *Odyssey* of Homer, might be degraded into the class of romances, as *Le Beau Deconnu* is elevated into that of epic poems, there lies in ordinary speech, and in common sense, as wide a distinction between these two classes of composition, as there is betwixt the rude mystery or morality of the middle ages, and the regular drama by which these were succeeded. Where the art and the ornaments of the poet chiefly attract our attention; where each part of the narrative bears a due proportion to the others, and the whole draws gradually towards a final and satisfactory conclusion; where the characters are sketched with force, and sustained with precision; where the narrative is enlivened and adorned with so much, and no more, of poetical ornament and description, as may adorn, without impeding its progress; where this art and taste are displayed, supported, at the same time, by a sufficient tone of genius, and art of composition, the work produced must be termed an epic poem, and the author may claim his seat upon the high and honoured throne occupied by Homer, Virgil, and Milton. On the other hand, when a story languishes in tedious and minute details, and relies for the interest which it proposes to excite, rather upon the wild excursions of an unbridled fancy, than upon the skill of the poet; when the supernatural and the extraordinary are relied upon exclusively as the supports of the interest, the author, though his production may be distinguished by occasional flashes of genius, and though it may be interesting to the historian, as containing some minute fragments of real events, and still more so to the antiquary, from the light which it throws upon ancient manners, is still no more than a humble romancer, and his work must rank amongst those rude ornaments of a dark age, which are at present the subject of our consideration. Betwixt the extremes of the two classes of composition, there must, no doubt, exist many works, which partake in some degree of the character of both; and after having assigned most of them, each to their proper class, according as they are distinguished by regularity of composition and poetical talent, or, on the contrary, by extravagance of imagination, and irregularity of detail, there may still remain some, in which these properties are so equally balanced, that it may be difficult to say to which class they belong. But although this may be the case in a very few instances, our taste and habits readily acknowledge as complete and absolute a difference betwixt the epopeia and romance, as can exist betwixt two distinct species of the same generic class.

We have said of romance, that it first appears in the form of metrical history, professes to be a narrative of real facts, and is, indeed, nearly allied to such history as an early state of society affords; which is always exaggerated by the prejudices and partialities of the tribe to which it belongs, as well as deeply marked by their idolatry and superstition. These it becomes the trade of the romancers still more to exaggerate, until the thread of truth can scarce be discerned in the web of fable which involves it; and we are compelled to renounce all hope of deriving serious or authentic information from the materials upon which the compounders of fiction have been so long at work, from one generation to another, that they have at length obliterated the very shadow of reality or even probability.

The view we have given of the origin of romance will be found to agree with the facts which the researches of so many active investigators of this curious subject have been able to ascertain. It is found, for example, and we will produce instances in viewing the progress of romance in particular countries, that the earliest productions of this sort, known to exist, are short narrations or ballads, which were probably sung on solemn or festive occasions, recording the deeds and praises of some famed champion of the tribe and country, or perhaps the history of some remarkable victory or signal defeat, calculated to interest the audience by the associations which the song awakens. These poems, of which very few can now be supposed to exist, are not without flashes of genius, but brief, rude, and often obscure, from real antiquity or affected sublimity of diction. The song on the battle of Brunanburgh, preserved in the *Saxon Chronicle*, is a genuine and curious example of this aboriginal style of poetry.

---

[1] *Reliques of Ancient English Poetry*, III. xxvii. The Prelate is citing a discourse on epic poetry, prefixed to *Telemachus*.

Temporal and spiritual romances.

Even at this early period,[1] there may be observed a distinction betwixt what may be called the *Temporal* and *Spiritual* romances; the first destined to the celebration of worldly glory; the second to recording the deaths of martyrs and the miracles of saints; both which themes unquestionably met with an almost equally favourable reception from their hearers. But although most nations possess, in their early species of literature, specimens of both kinds of romance, the proportion of each, as was naturally to have been expected, differs according as the genius of the people amongst whom they occur leaned towards devotion or military enterprise. Thus, of the Saxon specimens of poetry, which manuscripts still afford us, a very large proportion is devotional, amongst which are several examples of the spiritual romance, but very few, indeed, of those respecting warfare or chivalry. On the other hand, the Norman language, though rich in examples of both kinds of romances, is particularly abundant in that which relates to battle and warlike adventure. The Christian Saxons had become comparatively pacific, while the Normans were certainly accounted the most martial people in Europe.

However different the spiritual romance may be from the temporal in scope and tendency, the nature of the two compositions did not otherwise greatly differ. The structure of verse and style of composition was the same; and the induction, even when the most serious subject was undertaken, exactly resembled that with which minstrels introduced their idle tales, and often contained allusions to them. Warton quotes a poem on the Passions, which begins,

> I hereth one lutele tale, that Ich eu wille telle,
> As wi vyndeth hit invrite in the godspelle,
> Nuz hit nouht of Carlemeyne ne of the Duzpere,
> Ac of Criste's thruurynge, &c.

The temporal romances, on the other hand, often commenced by such invocations of the Deity, as would only have been in place when a much more solemn subject was to be agitated. The exordium of the Romance of *Ferumbras* may serve as an example of a custom almost universal;

> God in glorye of mightis moost
> That all things made in sapience,
> By virtue of Word and Holy Gooste,
> Giving to men great excellence, &c.

The distresses and dangers which the knight endured for the sake of obtaining earthly fame and his mistress's favour, the saint or martyr was exposed to for the purpose of securing his rank in heaven, and the favour of some beloved and peculiar patron saint. If the earthly champion is in peril from monsters, dragons, and enchantments, the spiritual hero is represented as liable to the constant assaults of the whole invisible world, headed by the ancient dragon himself. If the knight is succoured at need by some favouring fairy or protecting genius, the saint is under the protection not only of the whole heavenly host, but of some one divine patron or patroness who is his especial auxiliary. Lastly, the conclusion of the romance, which usually assigns to the champion a fair realm, an abundant succession, and a train of happy years, consigns to the martyr his fane and altar upon earth, and in heaven his seat among saints and angels, and his share in a blessed eternity. It remains but to say, that the style and language of these two classes do not greatly differ, and that the composers of both employ the same structure of rhythm and of language, and draw their ideas and their incidents from similar sources; so that, having noticed the existence of the spiritual romance, it is unnecessary for the present to prosecute this subject farther.

Another early and natural division of these works of fiction seems to have arranged them into *Serious* and *Comical*. The former were by far the most numerous, and examples of the latter are in most countries comparatively rare. Such a class, however, existed, as proper romances, even if we hold the comic romance distinct from the *Contes* and *Fabliaux* of the French, and from such jocular English narratives as the *Wife Lapt in Moral's Skin*, *The Friar and the Boy*, and similar humorous tales; of which the reader will find many examples in Ritson's *Ancient English Poetry*, and in other collections. The scene of these *gestes* being laid in low, or at least in ordinary life, they approach in their nature more nearly to the class of novels, and may perhaps be considered as the earliest specimens of that kind of composition. But the proper comic romance was that in which the high terms and knightly adventures of chivalry were burlesqued, by ascribing them to clowns or others of a low and mean degree. Such compositions formed, as it were, a parody on the serious romance, to which they bore the same proportion as the antimasque, studiously filled with grotesque, absurd, and extravagant characters, "entering," as the stage direction usually informs us, "to a confused music," bore to the masque itself, where all was dignified, noble, stately, and harmonious.

An excellent example of the comic romance is the *Tournament of Tottenham*, printed in Piercy's *Reliques*, in which a number of clowns are introduced practising one of these warlike games, which were the exclusive prerogative of the warlike and noble. They are represented making vows to the swan, the peacock, and the ladies; riding a tilt on their clumsy cart horses, and encountering each other with ploughshares and flails; whilst their defensive armour consisted of great wooden bowls and troughs, by way of helmets and cuirasses. The learned editor seems to have thought this singular composition was like Don Quixote, with which he compares it, a premeditated effort of satire, written to expose the grave and fantastic manners of the serious romance. This is considering the matter too deeply, and ascribing to the author a more critical purpose than he was probably capable of conceiving. It is more natural to suppose that his only ambition was to raise a laugh, by ascribing to the vulgar the manners and exercises of the noble and valiant; as in the well-known farce of *High Life Below Stairs*, the ridicule is not directed against the manners described, but against the menials who affect those that are only befitting their superiors. The *Hunting of the Hare*, published in the collection formed by the late industrious and accurate Mr. Weber, is a comic romance of the same order. A yeoman informs the inhabitants of a country hamlet that he has found a hare sitting, and invites them to come to course her. They attend, accordingly, with all the curs and mastiffs of their village, and the unsportsman-like manner in which the inexperienced huntsmen and their irregular pack conduct themselves, forms the interest of the piece. It can hardly be supposed the satire is directed against the sport of hunting itself; since the whole ridicule arises out of the want of the necessary knowledge of its rules, incident to the ignorance and inexperience of the clowns who undertook to practise an art peculiar to gentlemen. The ancient poetry of Scotland furnishes several examples of this ludicrous style of romantic composition; as the *Tournament at the Drum*, and the *Justing of Watson and Barbour*, by Sir David Lindsay. It is probable that these mock encounters were sometimes acted in earnest; at least King James I. is accused of witnessing such practical jests; "sometimes presenting David Droman and Archie Armstrong, the king's fool, on the back of other fools, to tilt at one another till they fell together by the ears."—(Sir Anthony Weldon's *Court of King James*.)

---

[1] The religious romances of *Barlaam* and *Jehosephat* were composed by John of Damascus in the eighth century.

In hastily noticing the various divisions of the romance, we have in some degree delayed our promised account of its rise and progress; an inquiry which we mean chiefly to confine to the romance of the middle ages. It is indeed true that this species of composition is common to almost all nations, and that even if we deem the *Iliad* and *Odyssey* compositions too dignified by the strain of poetry in which they are composed to bear the name of metrical romances; yet we have the pastoral romance of *Daphnis and Chloe*, and the historical romance of *Theagenes and Chariclea*, which are sufficiently accurate specimens of that style of composition. The *Milesian fables* and the romances of Antonius Diogenes, described by Photius, could they be recovered, would also be found to belong to the same class. It is impossible to avoid noticing that the Sybarites, whose luxurious habits seem to have been intellectual, as well as sensual, were peculiarly addicted to the perusal of the Milesian fables; from which we may conclude that they were not of that severe kind which inspired high thoughts and martial virtues. But there would be little advantage derived from extending our researches into the ages of classical antiquity respecting a class of compositions which, though they existed then, as in almost every stage of society, were neither so numerous nor of such high repute as to constitute any considerable portion of that literature.

Want of space also may entitle us to dismiss the consideration of the Oriental romances, unless in so far as in the course of the middle ages they came to furnish materials for enlarging and varying the character of the romances of knight-errantry. That they existed early, and were highly esteemed both among the Persians and Arabians, has never been disputed; and the most interesting light has been lately thrown on the subject by the publication of *Antar*, one of the most ancient, as well as most rational, if we may use the phrase, of the Oriental fictions. The Persian romance of the *Sha-Nameh* is well known to Europeans by name, and by copious extracts; and the love-tale of *Mejnoun and Leilah* is also familiar to our ears, if not to our recollections. Many of the fictions in the extraordinary collection of the *Arabian Tales* approach strictly to the character of romances of chivalry; although in general they must be allowed to exceed the more tame northern fictions in dauntless vivacity of invention, and in their more strong tendency to the marvellous. Several specimens of the comic romance are also to be found mingled with those which are serious; and we have the best and most positive authority that the recital of these seductive fictions is at this moment an amusement as fascinating and general among the people of the East, as the perusal of printed romances and novels among the European public. But a minute investigation into this particular species of romance would lead us from our present field, already sufficiently extensive for the limits to which our plan confines it.

The European Romance, wherever it arises, and in whatsoever country it begins to be cultivated, had its origin in some part of the real or fabulous history of that country; and of this we will produce, in the sequel, abundant proofs. But the simple tale of tradition has not passed through many mouths, ere some one, to indulge his own propensity for the wonderful, or to secure by novelty the attention of his audience, augments the meagre chronicle with his own apocryphal inventions. Skirmishes are magnified into great battles; the champion of a remote age is exaggerated into a sort of demi-god; and the enemies whom he encountered and subdued are multiplied in number, and magnified in strength, in order to add dignity to his successes against them. Chaunted to rhythmical numbers, the songs which celebrate the early valour of the fathers of the tribe become its war-cry in battle, and men march to conflict hymning the praises and the deeds of some real or supposed precursor who had marshalled their fathers in the path of victory. No reader can have forgotten that when the decisive battle of Hastings commenced, a Norman minstrel, Taillefer, advanced on horseback before the invading host, and gave the signal for onset, by singing the *Song of Roland*, that renowned nephew of Charlemagne, of whom romance speaks so much, and history so little; and whose fall, with the chivalry of Charles the great in the pass of Roncesvalles, has given rise to such clouds of romantic fiction, that its very name has been for ever associated with it. The remarkable passage has been often quoted from the *Brut of Wace*, an Anglo-Norman metrical chronicle.

> Taillefer, qui moult bien chantout
> Sur un cheval qui tost alout,
> Devant le Duc alout chantant
> De Karlemaigne et de Rollant,
> Et d'Oliver et des vassals,
> Qui morurent en Rencevals.

Which may be thus rendered:

> Taillefer, who sung both well and loud,
> Came mounted on a courser proud;
> Before the Duke the minstrel sprung,
> And loud of Charles and Roland sung,
> Of Oliver and champions mo,
> Who died at fatal Ronçevaux.

This champion possessed the sleight-of-hand of the juggler, as well as the art of the minstrel. He tossed up his sword in the air, and caught it again as he gallopped to the charge, and showed other feats of dexterity. Taillefer slew two Saxon warriors of distinction, and was himself killed by a third. Ritson, with less than his usual severe accuracy, supposed that Taillefer sung some part of a long metrical romance upon Roland and his history; but the words *chanson*, *cantilena*, and *song*, by which the composition is usually described, seems rather to apply to a brief ballad or national song; which is also more consonant with our ideas of the time and place where it was chaunted.

But neither with these romantic and metrical chronicles did the mind long remain satisfied; more details were demanded, and were liberally added by the invention of those who undertook to cater for the public taste in such matters. The same names of kings and champions, which had first caught the national ear, were still retained, in order to secure attention, and the same assertions of authenticity, and of reference to real history, were stoutly made both in the commencement and in the course of the narrative. Each nation, as will presently be seen, came at length to adopt to itself a cycle of heroes like those of the *Iliad;* a sort of common property to all minstrels who chose to make use of them, under the condition always, that the general character ascribed to each individual hero was preserved with some degree of consistency. Thus, in the romances of *The Round Table*, Gawain is usually represented as courteous; Kay as rude and boastful; Mordred as treacherous; and Sir Launcelot as a true though a sinful lover, and in all other respects a model of chivalry. Amid the Paladins of Charlemagne, whose cycle may be considered as peculiarly the property of French in opposition to Anglo-Norman romance, Gan, or Ganelon of Mayence, is always represented as a faithless traitor engaged in intrigues for the destruction of Christianity; Roland as brave, unsuspicious, devotedly loyal, and somewhat simple in his disposition; Renaud, or Rinaldo, is painted with all the properties of a borderer, valiant, alert, ingenious, rapacious and unscrupulous. The same conventional distinctions may be traced in the history of the Nibelung, a composition of Scandinavian origin, which has supplied matter for so many Teutonic adventurers. Meister Hildebrand, Etzel, Theodorick, and the champion Hogan, as well as Chrimhelda and the females introduced, have the same individuality of character, which is ascribed, in Homer's immortal writings, to the wise Ulysses, the brave but relentless Achilles, his more gentle friend Patroclus, Sarpedon, the favourite of the gods, and Hector, the protector of mankind. It was not permitted to the invention of a Greek poet to make Ajax a dwarf, or Teucer a giant, Thersites a hero, or Diomedes a coward; and it seems to have been under similar restrictions respecting consistency that the ancient romancers exercised their ingenuity upon the materials supplied them by their predecessors. But, in other respects, the whole store of romantic history and tradition was free to all as a joint stock in trade, on which each had a right to draw as suited his particular purposes. He was at liberty not only to select a hero out of known and established names which had been the theme of others, but to imagine a new personage of his own pure fancy, and combine him with the heroes of Arthur's Table or Charlemagne's Court, in the way which best suited his fancy. He was permitted to excite new wars against those bulwarks of Christendom, invade them with fresh and innumerable hosts of Saracens, reduce them to the last extremity, drive them from their thrones, and lead them into captivity, and again to relieve their persons, and restore their sovereignty, by events and agents totally unknown in their former story.

In the characters thus assigned to the individual personages of romantic fiction, it is possible there might be some slight foundation in remote tradition, as there were also probably some real grounds for the existence of such persons, and perhaps for a very few of the leading circumstances attributed to them. But these realities only exist as the few grains of wheat in the bushel of chaff, incapable of being winnowed out, or cleared from the mass of fiction with which each new romancer had in his turn overwhelmed them. So that romance, though certainly deriving its first original from the pure fount of history, is supplied, during the course of a very few generations, with so many tributes from the imagination, that at length the very name comes to be used to distinguish works of pure fiction.

When so popular a department of poetry has attained this decided character, it becomes time to inquire who were the composers of these numerous, lengthened, and once admired narratives which are called metrical romances, and from whence they drew their authority. Both these subjects of discussion have been the source of great controversy among antiquaries; a class of men who, be it said with their forgiveness, are apt to be both positive and polemical upon the very points which are least susceptible of proof, and which are least valuable if the truth could be ascertained; and which, therefore, we would gladly have seen handled with more diffidence, and better temper, in proportion to their uncertainty.

The Minstrels.

The late venerable Dr. Percy, Bishop of Dromore, led the way unwarily to this dire controversy, by ascribing the composition of our ancient heroic songs and metrical legends, in rather too liberal language, to the minstrels, that class of men by whom they were generally recited. This excellent person, to whose memory the lovers of our ancient lyre must always remain so deeply indebted, did not, on publishing his work nearly fifty years ago, see the rigid necessity of observing the utmost and most accurate precision either in his transcripts or his definitions. The study which he wished to introduce was a new one; it was his object to place it before the public in an engaging and interesting form; and, in consideration of his having obtained this important point, we ought to make every allowance not only for slight inaccuracies, but for some hasty conclusions, and even exaggerations, with which he was induced to garnish his labour of love. He defined the minstrels, to whose labours he chiefly ascribed the metrical compositions on which he desired to fix the attention of the public, as "an order of men in the middle ages, who subsisted by the arts of poetry and music, and sung to the harp verses composed by themselves or others."[1] In a very learned and elegant essay upon the text thus announced, the reverend Prelate in a great measure supported the definition which he had laid down; although it may be thought that, in the first editions at least, he has been anxious to view the profession of the minstrels on their fairest and most brilliant side; and to assign to them a higher station in society than a general review of all the passages connected with them will permit us to give to a class of persons who either lived a vagrant life, dependent on the precarious taste of the public for a hard-earned maintenance, or, at best, were retained as a part of the menial retinue of some haughty baron, and in a great measure identified with his musical band.

The late acute, industrious, and ingenious Mr. Joseph Ritson, whose severe accuracy was connected with an unhappy eagerness and irritability of temper, took advantage of the exaggerations occasionally to be found in the Bishop's *Account of Ancient Minstrelsy*, and assailed him with terms which may be termed any thing but courteous. Without finding an excuse either in the novelty of the studies in which Percy had led the way, or in the vivacity of imagination which he did not himself share, he proceeded to arraign each trivial inaccuracy as a gross fraud, and every deduction which he considered to be erroneous as a wilful untruth, fit to be stigmatised with the broadest appellation by which falsehood can be distinguished. Yet there is so little room for this extreme loss of temper, that, upon a recent perusal of both these ingenious essays, we were surprised to find that the reverend editor of the *Reliques*, and the accurate antiquary, have differed so very little as, in essential facts, they appear to have done. Quotations are, indeed, made by both with no sparing hand, and hot arguments; and, on one side at least, hard words are unsparingly employed; while, as is said to happen in theological polemics, the contest grows warmer in proportion as the ground concerning which it is carried on is narrower and more insignificant. Their systems, in reality, do not essentially differ.

Ritson is chiefly offended at the sweeping conclusion in which Percy states the minstrels as subsisting by the arts of poetry and music, and reciting to the harp verses composed by themselves and others. He shows very successfully that this definition is considerably too extensive, and that the term minstrel comprehended, of old, not merely those who recited to the harp or other instrument romances and ballads, but others who were distinguished by their skill in instrumental music only; and, moreover, that jugglers, sleight-of-hand performers, dancers, tumblers, and such like subordinate artists, who were introduced to help away the tedious hours in an ancient feudal castle, were also comprehended under the general term of minstrel. But although he distinctly proves that Percy's definition applied only to one class of the persons termed minstrels, those, namely, who sung or recited verses, and in many cases of their own composition; the bishop's position remains unassailable, in so far as relates to one general class, and these the most distinguished during the middle ages. All minstrels did not use the harp, and recite or compose romantic poetry; but it cannot be denied that such was the occupation of the most eminent of the order. This Ritson has rather admitted than denied; and the number of quotations which his industry has brought together, rendered such an admission inevitable.

---

[1] *Essay on Ancient Minstrels in England* prefixed to the first volume of Bishop Percy's *Reliques*.

Indeed, the slightest acquaintance with ancient romances of the metrical class, shows us that they were composed for the express purpose of being recited, or, more properly, chaunted to some simple tunc or cadence for the amusement of a large audience. Our ancestors, as they were circumscribed in knowledge, were also more limited in conversational powers than their enlightened descendants; and it seems probable, that in their public festivals, there was great advantage found in the presence of a minstrel who should recite some popular composition on their favourite subjects of love and war, to prevent those pauses of discourse which sometimes fall heavily on a company, even of the present accomplished age, and to supply an agreeable train of ideas to those guests who had few of their own. It is, therefore, almost constantly insinuated, that the romance was to be chaunted or recited to a large and festive society; and in some part or other of the piece, generally at the opening, there is a request of attention on the part of the performer; and hence, the perpetual "Lythe and listen lordings free," which in those, or equivalent words, forms the introduction to so many romances. As, for example, in the old poem of *Guy and Colbrand*, the minstrel speaks of his own occupation:

> When meat and drink is great plentye,
> Then lords and ladyes still will be,
> And sit and solace lythe;
> Then it is time for mee to speake,
> Of kern knights and kempes greate,
> Such carping for to kythe.

Chaucer, also, in his rhyme of Sir Thopas, assigns to the minstrels of his hero's household the same duty of reciting romances of spiritual or secular heroes. for the good knight's pastime while arming himself for battle:

> "Do cum," he sayd, "my minestrales,
> And jestours for to tellen tales
> Anon in min arming,
> Of romaunces that ben reales,
> Of popes and of cardinales,
> And eke of love-longing."

Not to multiply quotations, we will only add one of some importance, which must have escaped Ritson's researches; for his editorial integrity was such, as rendered him incapable of suppressing evidence on either side of the question. In the old romance or legend of *True Thomas and the Queen of Elfland*, Thomas the Rhymer, himself a minstrel, is gifted by the Queen of the Faery with the faculties of music and song. The answer of Thomas is not only conclusive as to the minstrel's custom of recitation, but shows that it was esteemed the highest branch of his profession, and superior as such to mere instrumental music:

> "To harp and carp Thomas wheresoever ye gon,
> Thomas take the these with the"——
> "Harping," he said, "ken I non,
> For tong is chefe of Mynstralse."[1]

We, therefore, arrive at the legitimate conclusion, that although, under the general term minstrels, were comprehended many who probably entertained the public only with instrumental performances, with ribald tales, with jugglery, or farcical representations, yet one class amongst them, and that a numerous one, made poetical recitation their chief, if not their exclusive occupation. The memory of these men was, in the general case, the depository of the pieces which they recited; and hence, although a number of their romances still survive, very many more have doubtless fallen into oblivion.

That the minstrels were also the authors of many of these poems, and that they altered and enlarged others, is a matter which can scarcely be doubted, when it is proved that they were the ordinary reciters of them. It was as natural for a minstrel to become a poet or composer of romances, as for a player to be a dramatic author, or a musician a composer of music. Whatever individual among a class, whose trade it was to recite poetry, felt the least degree of poetical enthusiasm in a profession so peculiarly calculated to inspire it, must, from that very impulse, have become an original author, or translator at least; thus giving novelty to his recitations, and acquiring additional profit and fame. Bishop Percy, therefore, states the case fairly in the following passage: "It can hardly be expected that we should be able to produce regular and unbroken annals of the minstrel art and its professors, or have sufficient information, whether every minstrel or bard composed himself, or only repeated, the songs he chaunted. Some probably did the one and some the other; and it would have been wonderful indeed, if men, whose peculiar profession it was, and who devoted their time and talents to entertain their hearers with poetical compositions, were peculiarly deprived of all poetical genius themselves, and had been under a physical incapacity of composing those common popular rhymes, which were the usual subjects of their recitation."[2] While, however, we acquiesce in the proposition, that the minstrels composed many, perhaps the greater part of the metrical romances which they sung, it is evident they were frequently assisted in the task by others who, though not belonging to this profession, were prompted by leisure and inclination to enter upon the literary or poetical department as amateurs. These very often belonged to the clerical profession, amongst whom relaxation of discipline, abundance of spare time, and impatience of the routine of ceremonious duties, often led individuals into worse occupations than the listening to or composing metrical romances. It was in vain that both the poems and the minstrels who recited them were, by statute, debarred from entering the more rigid monasteries. Both found their way frequently to the refectory, and were made more welcome than brethren of their own profession; as we may learn from a memorable *Gest*, in which two poor travelling priests, who had been received into a monastery with acclamation, under the mistaken idea of their being minstrels, are turned out in disgrace, when it is discovered that they were indeed capable of furnishing spiritual instruction, but understood none of the entertaining arts with which the hospitality of their convent might have been repaid by itinerant bards.

Nay, besides a truant disposition to a forbidden task, many of the grave authors may have alleged, in their own defence, that the connexion between history and romance was not in their day entirely dissolved. Some eminent men exercised themselves in both kinds of composition; as, for example, Maitre Wace, canon of Caen, in Normandy, who, besides the metrical chronicle of *Le Brut*, containing the earliest history of England, and other historical legends, wrote, in 1155, the *Roman de Chevalier de Lyon*, probably the same translated under the title of *Ywain* and *Gawain*. Lambert li Cors, and Benoit de Saint-Maur, seem both to have been of the clerical order; and, perhaps, Chretien de Troyes, a most voluminous author of romance, was of the same profession. Indeed, the extreme length of many romances being much greater than any minstrel could undertake to sing at one or even many sittings, may induce us to refer them to men of a more sedentary occupation than those wandering poets. The religious romances were, in all probability, the works of such churchmen as might wish to reconcile an agreeable occupation with their religious profession. All which circumstances must be received as exceptions from the general proposition, that the romances in metre were the composition of the minstrels by whom they were recited or sung, though they must still leave Percy's proposition to a certain extent unimpeached.

---

[1] Jamieson's *Popular Ballads*, vol. ii. p. 27.

[2] *Essay on the Ancient Minstrels*, p. 30.

Another authority of ancient date, the *Chronicle* of Bertrand Guesclin, distinctly attributes the most renowned romances to the composition of the minstrels by whom they were sung. As the passage will be afterwards more fully quoted, we must here only say, that after enumerating Arthur, Launcelot, Godfrey, Roland, and other champions, he sums up his account of them as being the heroes

> De quoi cils minestriers font les nobles romans.

To explain the history of Romance, it is necessary to digress a little further concerning the condition of the minstrels by whom these compositions were often made, and, generally speaking, preserved and recited. And here, it must be confessed, that the venerable Prelate has, perhaps, suffered his love of antiquity, and his desire to ennoble the productions of the middle ages, a little to overcolour the importance and respectability of the minstrel tribe; although his opponent Ritson has, on the other hand, seized on all circumstances and inferences which could be adduced to prove the degradation of the minstrel character, without attending to the particulars by which these depreciating circumstances were qualified. In fact, neither of these excellent antiquaries has cast a general or philosophical glance on the necessary condition of a set of men who were by profession the instruments of the pleasure of others during a period of society such as was presented in the middle ages.

In a very early period of civilisation, ere the division of tribes had been generally adopted, and while each tribe may be yet considered as one great family, and the nation as an union of such independent tribes, the poetical art, so nearly allied to that of oratory or persuasion, is found to ascertain to its professors a very high rank. Poets are then the historians and often the priests of the tribe. Their command of language, then in its infancy, excites not merely pleasure, but enthusiasm and admiration. When separated into a distinct class, as was the case with the Celtic bards, and, perhaps, with the skalds of Scandinavia, they rank high in the scale of society, and we not only find kings and nobles listening to them with admiration, but emulous of their art, and desirous to be enrolled among their numbers. Several of the most renowned northern kings and champions valued themselves as much upon their powers of poetry as on their martial exploits; and of the Welsh princes, the Irish kings, and the Highland chiefs of Scotland, very many practised the arts of poetry and music. Llwarch Hen was a prince of the Cymraig, Brian Boromhe, a harper and a musician, and without resorting to the questionable authenticity of Ossian, several instances of the same kind might be produced in the Highlands.

But, in process of time, when the classes of society come to assume their usual gradation with respect to each other, the rank of professional poets is uniformly found to sink gradually in the scale, along with that of all others whose trade it is to contribute mere amusement. The professional poet, like the player or the musician, becomes the companion and soother only of idle and convivial hours; his presence would be unbecoming on occasions of gravity and importance; and his art is accounted at best an amusing but useless luxury. Although the intellectual pleasure derived from poetry or from the exhibition of the drama be of a different and much higher class than that derived from the accordance of sounds, or from the exhibition of feats of dexterity, still it will be found that the opinions and often the laws of society, while individuals of these classes are cherished and held in the highest estimation, have degraded the professions themselves among its idle, dissolute, and useless appendages. Although it may be accounted ungrateful in mankind thus to reward the instruments of their highest enjoyments, yet some justification is usually to be drawn from the manners of the classes who were thus lowered in public opinion. It must be remembered, that, as professors of this joyous science, as it was called, the minstrels stood in direct opposition to the more severe part of the Catholics, and to the monks in particular, whose vows bound them to practise virtues of the ascetic order, and to look upon every thing as profane which was connected with mere worldly pleasure. The manners of the minstrels themselves gave but too much room for clerical censure. They were the usual assistants at scenes, not merely of conviviality, but of license; and as the companions and encouragers of revelling and excess, they became contemptible in the eyes, not only of the aged and the serious, but of the libertine himself, when his debauch palled on his recollection. The minstrels, no doubt, like their brethren of the stage, sought an apology in the corrupted taste and manners of their audience, with which they were obliged to comply, under the true but melancholy condition that

> —they who live to please must please to live.

But this very necessity, rendered more degrading by their increasing numbers and decreasing reputation, only accelerated the total downfall of their order, and the general discredit and neglect into which they had fallen. The statute of the 39th of Queen Elizabeth, passed at the close of the sixteenth century, ranks those dishonoured sons of song among rogues and vagabonds, and appoints them to be punished as such; and the occupation, though a vestige of it was long retained in the habits of travelling ballad-singers and musicians, sunk into total neglect and contempt. Of this we shall have to speak hereafter; our business being at present with those romances, which, while still in the zenith of their reputation, were the means by which the minstrels, at least the better and higher class amongst them, recommended themselves to the favour of their noble patrons, and of the audiences whom they addressed.

It may be presumed, that, although the class of minstrels, like all who merely depend upon gratifying the public, carried in their very occupation the evils which first infected, and finally altogether depraved their reputation; yet, in the earlier ages, their duties were more honourably estimated, and some attempts were made to introduce into their motley body the character of a regular establishment, subjected to discipline and subordination. Several individuals, both of France and England, bore the title of king of minstrels, and were invested probably with some authority over the others. The serjeant of minstrels is also mentioned; and Edward IV. seems to have attempted to form a guild or exclusive corporation of minstrels. John of Gaunt, at an earlier period, established (between jest and earnest, perhaps) a court baron of minstrels, to be held at Tilbury. There is no reason, however, to suppose that the influence of their establishments went far in restraining the licence of a body of artists so unruly as well as numerous.

It is not, indeed, surprising that individuals, whose talents in the arts of music or of the stage rise to the highest order, should, in a special degree, attain the regard and affection of the powerful, acquire wealth, and rise to consideration; for, in such professions, very high prizes are assigned only to pre-eminent excellence; while ordinary or inferior practisers of the same art may be said to draw in the lottery something worse than a mere blank. Garrick, in his chariot, and whose company was courted for his wit and talent, was, after all, by profession, the same with the unfortunate stroller, whom the British laws condemn as a vagabond, and to whose dead body other countries refuse even the last rites of Christianity. In the same manner it is easy to suppose that, when in compliance with the taste of their age, monarchs entertained their domestic minstrels,[1] those persons might be admitted to the most flattering intimacy with their royal masters; sleep within the royal chamber,[2] amass considerable fortunes, found hospitals,[3] and receive rewards singularly over-proportioned to the perquisites of the graver professions;[4] and even practise in company with their royal masters the pleasing arts of poetry and music, which all are so desirous of attaining;[5] whilst, at the same time, those who ranked lower in the same profession were struggling with difficulty to gain a precarious subsistence, and incurring all the disgrace usually attached to a vagabond life and a dubious character. In the fine arts, particularly, excellence is demanded, and mere mediocrity is held contemptible; and, while the favour with which the former is loaded, sometimes seems disproportioned to the utility of the art itself, nothing can exceed the scorn poured out on those who expose themselves by undertaking arts which they are unable to practise with success. Self-conceit, however, love of an idle life, and a variety of combined motives, never fail to recruit the lower orders of such idle professions with individuals by whose performances, and often by their private characters, the art which they have rashly adopted can only be discredited without any corresponding advantage to themselves. It is not, therefore, surprising that, while such distinguished examples of the contrary appeared amongst individuals, the whole body of minstrels, with the romances which they composed and sung, should be reprobated by graver historians in such severe terms as often occur in the monkish chronicles of the day.

Charac nd sty he ro- nances hivalry

Respecting the style of their composition, Du Cange informs us, that the minstrels sometimes devoted their strains to flatter the great, and sing the praises of those princes by whom they were protected; while he owns, at the same time, that they often recommended to their hearers the path of virtue and nobleness, and pointed out the pursuits by which the heroes of romance had rendered themselves renowned in song.[6] He quotes from the romance of *Bertrand Guesclin*, the injunction on those who would rise to fame in arms to copy the valiant acts of the Paladins of Charles, and the Knights of the Round Table, narrated in romances; and it cannot be denied, that those high tales, in which the virtues of generosity, bravery, devotion to his mistress, and zeal for the Catholic religion, were carried to the greatest height of romantic perfection in the character of the hero, united with the scenes passing around them, were of the highest importance in affecting the character of the age. The fabulous knights of romance were so completely identified with those of real history, that graver historians quote the actions of the former in illustration of, and as a corollary to the real events which they narrate.[7] The virtues recommended in romance were, however, only of that overstrained and extravagant cast which consisted with the spirit of chivalry. Great bodily strength, and perfection in all martial exercises, was the universal accomplishment inalienable from the character of the hero, and which each romancer had it in his power to confer. It was also easily in the composer's power to devise dangers, and to free his hero from them by the exertion of valour equally extravagant. But it was more difficult to frame a story which should illustrate the manners as well as the feats of chivalry; or to devise the means of evincing that devotion to duty, and that disinterested desire to sacrifice all to faith and honour;—that noble spirit of achievement which laboured for others more than itself—which form, perhaps, the fairest side of the system under which the noble youths of the middle ages were trained up. The sentiments of chivalry, as we have explained in our article on that subject, were founded on the most pure and honourable principles, but unfortunately carried into hyperbole and extravagance; until the religion of its professors approached to fanaticism, their valour to frensy, their ideas of honour to absurdity, their spirit of enterprise to extravagance, and their respect for the female sex to a sort of idolatry. All those extravagant feelings, which really existed in the society of the middle ages, were magnified and exaggerated by the writers and reciters of romance; and these given as resemblances of actual manners, became, in their turn, the glass by which the youth of the age dressed themselves; while the spirit of chivalry and of romance thus gradually threw light upon and enhanced each other.

The romances, therefore, exhibited the same system of manners which existed in the nobles of the age. The character of a true son of chivalry was raised to such a pitch of ideal and impossible perfection, that those who emulated such renown were usually contented to stop far short of the mark. The most adventurous and unshaken valour, a mind capable of the highest flights of romantic generosity, a heart which was devoted to the will of some fair idol, on whom his deeds were to reflect glory, and whose love was to reward all his toils; these were attributes which all aspired to exhibit who sought to rank high in the annals of chivalry; and such were the virtues which the minstrels celebrated. But, like the temper of a tamed lion, the fierce and dissolute spirit of the age often shewed itself through the fair varnish of this artificial system of manners. The valour of the hero was often stained by acts of cruelty, or freaks of rash desperation; his courtesy and munificence became solemn foppery and wild profusion; his love to his lady often demanded and received a requital inconsistent with the honour of the object; and those who affected to found their attachment on the purest and most delicate metaphysical principles, carried on their actual intercourse with a license altogether inconsistent with their sublime pretensions. Such were the real manners of the middle ages, and we find them so depicted in these ancient legends.

---

[1] Berdic *(Regis Joculator)*, the jongleur or minstrel of William the Conqueror, had, as appears from the Domesday record, three vills and five caracates of land in Gloucestershire without rent. Henry I. had a minstrel called Galfrid, who received an annuity from the abbey of Hyde.

[2] A minstrel of Edward I., during that prince's expedition to the Holy Land, slept within his tent, and came to his assistance when an attempt was made to assassinate him.

[3] The Priory and Hospital of Saint Bartholomew, in London, was founded in the reign of Henry I. by Royer or Raher, a minstrel of that prince.

[4] In 1441, the monks of Maxlock, near Coventry, paid a donation of four shillings to the minstrels of Lord Clinton for songs, harping, and other exhibitions, while, to a doctor who preached before the community in the same year, they assigned only sixpence.

[5] The noted anecdote of Blondel and his royal master, Richard Cœur de Lion, will occur to every reader.

[6] Ministelli dicti præsertim scurræ, mimi, joculatores, quos etiamnum vulgo *Menestreux* vel *Menestriers*, appellamus.——Porro ejusmodi scurrarum erat Principes, non suis duntaxat ludicris oblectare, sed et eorum aures variis avorum, adeoque ipsorum Principum laudibus, non sine assentatione, cum cantilenis et musicis instrumentis, demulcere.——Interdum etiam virorum insignium et heroum gesta, aut explicata et jucunda narratione commemorabant, aut suavi vocis inflectione, fidibusque decantabant, quo sic dominorum, cæterorumque qui his intererant ludicris, nobilium animos ad virtutem capessendam et summorum virorum imitationem accenderent: quod fuit olim apud Gallos Bardorum ministerium, ut auctor est Tacitus. Neque enim alios à *Ministellis*, veterum Gallorum *Bardos* fuisse pluribus probat Henricus Valesius ad 15. Ammiani.—*Chronicon* Bertrandi Guesclini:

> Qui veut avoir renom des bons et des vaillans,
> Il doit aler souvent à la pluie et au champ,
> Et estre en la bataille, ainsy que fu Rollans,
> Les quatre fils Haimon et Charlon li plus grans,
> Li Dus Lions de Bourges, et Guion de Connans,
> Perceval li Galois, Lancelot et Tristans,
> Alexandres, Artus, Godefroy li sachans,
> De quoy cils menestriers font les nobles Romans.

[7] Barbour, the Scottish historian, censures a Highland chief, when, in commending the prowess of Bruce in battle, he likened him to he Celtic hero, Fin Mac Coul, and says, he might in more mannerly fashion have compared him to Gaudifer, a champion celebrated in he romance of Alexander.

So high was the national excitation in consequence of the romantic atmosphere in which they seemed to breathe, that the knights and squires of the fourteenth and fifteenth centuries imitated the wildest and most extravagant emprises of the heroes of romance; and, like them, took on themselves the most extraordinary adventures to shew their own gallantry, and do most honour to the ladies of their hearts. The females of rank, erected into a species of goddesses in public, and often degraded as much below their proper dignity in more private intercourse, equalled in their extravagances the youth of the other sex. A singular picture is given by Knyghton of the damsels-errant who attended upon the solemn festivals of chivalry, in quest, it may reasonably be supposed, of such adventures as are very likely to be met with by such females as think proper to seek them. "These tournaments are attended by many ladies of the first rank and greatest beauty, but not always of the most untainted reputation. These ladies are dressed in party-coloured tunics, one-half of one colour and the other half of another; their lirripipes, or tippets, are very short; their caps remarkably little, and wrapt about their heads with cords; their girdles and pouches are ornamented with gold and silver; and they wear short swords, called *daggers*, before them, a little below their navels; they are mounted on the finest horses, with the richest furniture. Thus equipped, they ride from place to place in quest of tournaments, by which they dissipate their fortunes, and sometimes ruin their reputation."—(Knyghton, quoted in Henry's *History*, vol. viii. p. 402.)

The minstrels, or those who aided them in the composition of the romances, which it was their profession to recite, roused to rivalry by the unceasing demand for their compositions, endeavoured emulously to render them more attractive by subjects of new and varied interest, or by marvellous incidents which their predecessors were strangers to. Much labour has been bestowed, somewhat unprofitably, in endeavouring to ascertain the sources from which they drew the embellishments of their tales, when the hearers began to be tired of the unvaried recital of battle and tournament which had satisfied the simplicity of a former age. Percy has contended for the northern *Sagas* as the unquestionable origin of the romance of the middle ages. Warton conceived that the *Oriental fables*, borrowed by those minstrels who visited Spain, or who in great numbers attended the crusades, gave the principal distinctive colouring to those remarkable compositions; and a later system, patronised by later authors, has derived them, in a great measure, from the fragments of classical superstition, which continued to be preserved after the fall of the Roman empire. All those systems seem to be inaccurate, in so far as they have been adopted, exclusively of each other, and of the general proposition, that fables of a nature similar to the romances of chivalry, modified according to manners and state of society, must necessarily be invented in every part of the world, for the same reason that grass grows upon the surface of the soil in every climate and in every country. "In reality," says Mr. Southey, who has treated this subject with his usual ability, "mythological and romantic tales are current among all savages of whom we have any full account; for man has his intellectual as well as his bodily appetites, and these things are the food of his imagination and faith. They are found wherever there is language and discourse of reason; in other words, wherever there is man. And in similar stages of civilization, or states of society, the fictions of different people will bear a corresponding resemblance, notwithstanding the difference of time and scene."[1]

To this it may be added, that the usual appearances and productions of nature offer to the fancy, in every part of the world, the same means of diversifying fictitious narrative by the introduction of prodigies. If in any romance we encounter the description of an elephant, we may reasonably conclude that a phenomenon, unknown in Europe, must have been borrowed from the east; but whosoever has seen a serpent and a bird, may easily aggravate the terrors of the former by conferring on a fictitious monster the wings of the latter; and whoever has seen or heard of a wolf, or lion, and an eagle, may, by a similar exertion of invention, imagine a griffin or hippogriff. It is imputing great poverty to the human imagination, to suppose that the *speciosa miracula*, which are found to exist in different parts of the world, must necessarily be derived from some common source; and perhaps we should not err more grossly in supposing that the various kinds of boats, skiffs, and rafts, upon which men have dared the ocean on so many various shores, have been all originally derived from the vessel of the Argonauts.

On the other hand, there are various romantic incidents and inventions of a nature so peculiar, that we may boldly, and at once, refer them to some particular and special origin. The tale of *Flora and Blanchefleur*, for example, could only be invented in the east, where the scene is laid, and the manners of which are observed with some accuracy. That of *Orfeo* and *Heurodis*, on the contrary, is the classical history of Orpheus and Eurydice, with the Gothic machinery of the elves or fairies, substituted for the infernal regions. But notwithstanding these and many other instances in which the subjects or leading incidents of romance can be distinctly traced to British or Armorican traditions, to the tales and history of classic antiquity, to the wild fables and rich imagery of Arabia, or to those darker and sterner themes which were first treated of by the Skalds of the north, it would be assuming greatly too much upon such grounds to ascribe the derivation of romantic fiction, exclusively to any one of these sources. In fact, the foundation of these fables lies deep in human nature, and the superstructures have been imitated from various authorities by those who, living by the pleasure which their lays of chivalry afforded to their audience, were especially anxious to recommend them by novelty of every kind; and were undoubtedly highly gratified when the report of travellers, or pilgrims, or perhaps their own intercourse with minstrels of other nations, enabled them to vary their usual narrations with circumstances yet unheard in bower and hall. Romance, therefore, was like a compound metal, derived from various mines, and in the different specimens of which, one metal or other was alternately predominant; and viewed in this light, the ingenious theories of those learned antiquaries, who have endeavoured to seek the origin of this style of fiction in one of these sources alone, to the exclusion of all others, seem as vain as that of travellers affecting to trace the proper head of the Nile to various different springs, all of which are owned to be accessary to form the full majesty of his current.

---

[1] Preface to Southey's edition of the *Morte D'Arthur*. Lond. 1817, 2 vols. 4to.

As the fashion of all things passes away, the metrical romances began gradually to decline in public estimation, probably on account of the depreciated character of the minstrels by whom they were recited. Tradition, says Ritson, is an alchemy, which converts gold into lead; and there is little doubt, that, in passing from mouth to mouth, and from age to age, the most approved metrical romances became gradually corrupted by the defect of memory of some reciters and the interpolations of others; since few comparatively can be supposed to have had recourse to the manuscripts in which some have been preserved. Neither were the reciters in the latter, as in the former times, supplied with new productions of interest and merit. The composition of the metrical romance was gradually abandoned to persons of an inferior class. The art of stringing together in loose verse a number of unconnected adventures, was too easy not to be practised by many who only succeeded to such a degree as was discreditable to the art, by shewing that mere mediocrity was sufficient to exercise it. And the licentious character, as well as the great number of those who, under the various names of glee-men, minstrels, and the like, traversed the country, and subsisted by this idle trade, brought themselves and their occupation into still greater contempt and disregard. With them, the long recitations formerly made at the tables of the great, were gradually banished into more vulgar society.

But though the form of those narratives underwent a change of fashion, the appetite for the fictions themselves continued as ardent as ever; and the prose romances which succeeded, and finally superseded those composed in verse, had a large and permanent share of popularity. This was, no doubt, in a great degree owing to the important invention of printing, which has so much contributed to alter the destinies of the world. The metrical romances, though in some instances sent to the press, were not very fit to be published in this form. The dull amplifications which passed well enough in the course of a half-heard recitation, became intolerable when subjected to the eye; and the public taste gradually growing more fastidious as the language became more copious, and the system of manners more complicated, graces of style and variety of sentiment were demanded instead of a naked and unadorned tale of wonders. The authors of the prose romance endeavoured, to the best of their skill, to satisfy this newly awakened and more refined taste. They used, indeed, the same sources of romantic history which had been resorted to by their metrical predecessors; and Arthur, Charlemagne, and all their chivalry, were as much celebrated in prose as ever they had been in poetic narrative. But the new candidates for public favour pretended to have recourse to sources of authentic information, to which their metrical predecessors had no access. They refer almost always to Latin, and sometimes to Greek originals, which certainly had no existence; and there is little doubt that the venerable names of the alleged authors are invented, as well as the supposed originals from which they are said to have translated their narratives. The following account of the discovery of *La tres elegante delicieux melliflue et tres plaisante Hystoire du tres noble Roy Perceforest* (printed at Paris in 1528 by Galliot du Pré,) may serve to show that modern authors were not the first who invented the popular mode of introducing their works to the world as the contents of a newly discovered manuscript. In the abridgment to which we are limitted, we can give but a faint picture of the minuteness with which the author announces his pretended discovery, and which forms an admirable example of the lie with a circumstance. In the year 1286, Count William of Hainault had, it is averred, crossed the seas in order to be present at the nuptials of Edward, and in the course of a tour through Britain, was hospitably entertained at an abbey situated on the banks of the Humber, and termed, it seems, Burtimer, because founded by a certain Burtimericus, a monarch of whom our annals are silent, but who had gained, in that place, a victory over the heathens of Germany. Here a cabinet, which was inclosed in a private recess, had been lately discovered within the massive walls of an ancient tower, and was found to contain a Grecian manuscript, along with a royal crown. The abbot had sent the latter to king Edward, and the Count of Hainault with difficulty obtained possession of the manuscript. He had it rendered from Greek into Latin by a monk of the abbey of Saint Landelain, and from that language it is said to have been translated into French by the author, who gives it to the world in honour of the blessed Virgin, and for the edification of nobleness and chivalry.

By such details, the authors of the prose romances endeavoured to obtain for their works a credit for authenticity which had been denied to the rhythmical legends. But in this particular they did great injustice to their contemned predecessors, whose reputations they murdered in order to rob them with impunity. Whatever fragments or shadowings of true history may yet remain hidden under the mass of accumulated fable, which had been heaped on them during successive ages, must undoubtedly be sought in the metrical romances; and according to the view of the subject which we have already given, the more the works approach in point of antiquity to the period where the story is laid, the more are we likely to find those historical traditions in something approaching to an authentic state. But those who wrote under the imaginary names of Rusticien de Puise, Robert de Borron, and the like, usually seized upon the subject of some old minstrel; and, recomposing the whole narrative after their own fashion, with additional characters and adventures, totally obliterated in that operation any shades which remained of the first, and probably authentic tradition, which was the original source of the elaborate fiction. Amplification was especially employed by the prose romancers, who, having once got hold of a subject, seem never to have parted with it until their power of invention was completely exhausted. The metrical romances, in some instances, indeed, ran to great length, but were much exceeded in that particular by the folios which were written on the same or similar topics by their prose successors. Probably the latter judiciously reflected that a book which addresses itself only to the eyes, may be laid aside when it becomes tiresome to the reader; whereas it may not always have been so easy to stop the minstrel in the full career of his metrical declamation.

Who, then, the reader may be disposed to inquire, can have been the real authors of those prolix works, who, shrouding themselves under borrowed names, derived no renown from their labours, if successful, and who, certainly, in the infant state of the press, were not rewarded with any emolument? This question cannot, perhaps, be very satisfactorily answered; but we may reasonably suspect that the long hours of leisure which the cloister permitted to its votaries, were often passed away in this manner; and the conjecture is rendered more probable, when it is observed that matters are introduced into those works which have an especial connection with sacred history, and with the traditions of the Church. Thus, in the curious romance of *Huon de Bourdeaux*, a sort of second part is added to that delightful history, in which the hero visits the terrestrial paradise, encounters the first murderer Cain, in the peformance of his penance, with more matter to the same purpose, not likely to occur to the imagination of a layman; besides, that the laity of the period were in general too busy and too ignorant to engage in literary tasks of any kind. The mystical portion of the romance of the *Round Table* seems derived from the same source. It may also be mentioned, that the audacious, and sometimes blasphemous assertions, which claimed for these fictions the credit due even to the inspired writings themselves, were likely to originate amongst Roman Catholic churchmen, who were but too familiar with such forgeries for the purpose of authenticating the legends of their superstition. One almost incredible instance of this impious specious of imposture occurs in the history of the *Saint Graal*, which curious mixture of mysticism and chivalry is ascribed by the unfearing and unblushing writer to the second person of the Trinity.

Churchmen, however, were by no means the only authors of these legends, although the *Sires Clercs*, as they were sometimes termed, who were accounted the chronicles of the times in which they lived, were usually in orders; and although it appears that it was upon them that the commands of the soveregins whom they served often imposed the task of producing new romances under the usual disguise of ancient chronicles translated from the learned languages, or otherwise collected from the ruins of antiquity. As education became improved, and knowledge began to be more generally diffused, individuals among the laity, and those of no mean rank, began to feel the necessity, as it may be called, of putting into a permanent form the "thick-coming fancies" which gleam along the imagination of men of genius. Sir Thomas Malony, who compiled the *Morte D'Arthur* from French originals, was a person of honour and worship; and Lord Berners, the excellent translator of Froissart, and author of a romance called *The Chevalier de la Cygne*, is an illustrious example that a nobleman of high estimation did not think his time misemployed on this species of composition. Some literary fame must therefore have attended these efforts; and perhaps less eminent authors might, in the latter ages, receive some pecuniary advantages. The translator of *Perceforest*, formerly mentioned, who appears to have been an Englishman or Fleming, in his address to the warlike and invincible nobility of France, holds the language of a professional author, who expected some advantage besides that of pleasing those whom he addressed; and who expresses proportional gratitude for the favourable reception of his former feeble attempts to please them. It is possible, therefore, that the publishers, these lions of literature, had begun already to admit the authors into some share of their earnings. Other printers, like the venerable Caxton, compiled themselves, or translated from other languages, the romances which they sent to the press; thus uniting in their own persons the three separate departments of author, printer, and publisher.

The prose romance did not, in the general conduct of the story, where digressions are heaped on digressions, without the least respect to the principal narrative, greatly differ from that of their metrical predecessors, being to the full as tedious and inartificial; nay, more so, in proportion as the new romances were longer than the old. In the transference from verse to prose, and the amplification which the scenes underwent in the process, many strong, forcible, and energetic touches of their original author have been weakened, or altogether lost; and the reader misses with regret some of the redeeming bursts of rude poetry which, in the metrical romance, make amends for many hundred lines of bald and rude versification. But, on the other hand, the prose romances were written for a more advanced stage of society, and by authors whose language was much more copious, and who certainly belonged to a more educated class than the ancient minstrels. Men were no longer satisfied with hearing of hard battles and direful wounds; they demanded at the hand of those who professed to entertain them, some insight into nature, or at least into manners; some description of external scenery, and a greater regard to probability both in respect of the characters which are introduced, and the events which are narrated. These new demands the prose romances endeavoured to supply to the best of their power. There was some attention shewn to relieve their story, by the introduction of new characters, and to illustrate these personages by characteristic dialogue. The lovers conversed with each other in the terms of metaphysical gallantry, which were used in real life; and from being a mere rhapsody of warlike feats, the romance began to assume the nobler and more artificial form of a picture of manners. It is in the prose folios of *Lancelot du Lac*, *Perceforest*, and others, that antiquaries find recorded the most exact accounts of fights, tournaments, feasts, and other magnificent displays of chivalric splendour; and as they descend into more minute description than the historians of the time thought worthy of their pains, they are a mine from which the painful student may extract much valuable information. This, however, is not the full extent of their merit. These ancient books, amid many pages of dull repetition and uninteresting dialogue, and notwithstanding the langour of an inartificial, protracted, and confused story, exhibit from time to time passages of deep interest, and situations of much novelty, as well as specimens of spirited and masculine writing. The general reader, who dreads the labour of winnowing out these valuable passages from the sterile chaff through which they are scattered, will receive an excellent idea of the beauties and defects of the romance from Tressan's *Corps d'Extraits de Romans de Chevalerie*, from Mr. Ellis's *Specimens of Early English Romances*, and Mr. Dunlop's *History of Fiction*.

These works continued to furnish the amusement of the most polished courts in Europe, so long as the manners and habits of chivalry continued to animate them. Even the sagacious Catherine of Medicis considered the romance of *Perceforest* as the work best qualified to form the manners and amuse the leisure of a young prince; since she impressed on Charles IX. the necessity of studying it with attention. But by degrees the progress of new opinions in religion, the promulgation of a stricter code of morality, together with the important and animating discussions which began to be carried on by means of the press, diverted the public attention from these antiquated legends. The Protestants of England, and the Huguenots of France, were rigorous in their censure of books of chivalry, in proportion as they had been patronized formerly under the Catholic system; perhaps because they helped to arrest men's thoughts from more serious subjects of occupation. The learned Ascham thus inveighs against the romance of *Morte D'Arthur*, and at the same time acquaints us with its having passed out of fashion: "In our forefathers' tyme, when papestrie, as a standyng poole, covered and overflowed all Englande, fewe bookes were read in our tongue, savyng certaine bookes of chivalrie, as they said for pastime and pleasure; which, as some say, were made in monasteries by idle monks, or wanton chanons. As, for example, *La Morte D'Arthur*, the whole pleasure of which booke standeth in two speciall poyntes, in open manslaughter, and bold bawdrye: in which booke they are counted the noblest knightes that do kill most men without any quarrell, and commit foulest adulteries by sutlest shiftes; as Sir Launcelote, with the wife of King Arthur his master; Sir Tristram, with the wife of King Marke his uncle; Sir Lamerocke, with the wife of King Lote, that was his own aunt. This is good stuffe for wise men to laughe at, or honest men to take pleasure at: yet I know, when God's Bible was banished the court, and *La Morte D'Arthur* received into the prince's chamber."[1]

The brave and religious La Noue is not more favourable to the perusal of romances than the learned Ascham; attributing to the public taste for these compositions the decay of morality amongst the French nobility. "The ancient fables whose relikes doe yet remain, namely, *Lancelot of the Lake, Pierceforest, Tristram, Giron the Courteous,* and such others, doe beare witnesse of this olde vanitie; herewith were men fed for the space of 500 yeeres, untill our language growing more polished, and our mindes more ticklish, they were driven to invent some nouelties wherewith to delight us. Thus came y^{e} bookes of *Amadis* into light among us in this last age. But to say y^{e} truth, *Spaine* bred thē, and *France* new clothed thē in gay garments. In y^{e} daies of *Henrie the Second* did they beare the chiefest sway, and I think if any man weuld then have reproved thē, he should have been spit at because they were of themselves playfellowes and maintainers to a great sort of persons; whereof some, after they had learned to amize in speech, their teeth watered, so desirous were they even to taste of some small morsels of the delicacies therein most livelie and naturally represented."[2] The gallant Marechal proceeds at considerable length to refute the arguments of those who contended that these books were intended as a spur to the practice of arms and honourable exercises amongst youth, and labours hard to shew that they teach dishonest practices both in love and in arms. It is impossible to suppress a smile when we find such an author as La Noue denouncing the introduction of spells, witchcrafts, and enchantments into these volumes, not because such themes are absurd and nonsensical, but because the representing such beneficent enchanters as Alquife and Urganda is, in fact, a vindication of those who traffic with the powers of darkness; and that those who love to read about sorceries and enchantments become, by degrees, familiarized with those devilish mysteries, and may at length be induced to have recourse to them in good earnest.

---

[1] *Works* of Roger Ascham, p. 254. 4to. edition.

The romances of chivalry did not, however, sink into disrepute under the stern rebuke of religious puritans or severe moralists, but became gradually neglected, as the customs of chivalry itself fell into disregard; when, of course, the books which breathed its spirit, and were written under its influence, ceased to produce any impression on the public mind, and, superseded by better models of composition, and overwhelmed with the ridicule of Cervantes, sunk by degrees into utter contempt and oblivion.

Other works of amusement, of the same general class, succeeded the proper romance of chivalry. Of these we shall take some notice hereafter, since we must here close our general view of the history of romance, and proceed briefly to give some account of those peculiar to the various European nations.

Romances of the different countries of Europe.

II. We can here but briefly touch upon a subject of great interest and curiosity, namely, the peculiar character and tone which the romance of chivalry received from the manners and early history of the nations amongst whom it is found to exist; and the corresponding question, in what degree each appears to have borrowed from other countries the themes of their own minstrels, or to have made use of materials common to the whole.

Northern romance.

Scandinavia, as was to be expected, may be safely considered as the richest country in Europe, in ancient tales corresponding with the character of romance; sometimes composed entirely in poetry or rhythm, sometimes in prose, and much more frequently in a mixture of prose, narrative, and lyrical effusions. Their well-known Skalds or bards held a high rank in their courts and councils. The character of a good poet was scarcely second to that of a gallant leader, and many of the most celebrated champions ambitiously endeavoured to unite both in their own persons. Their earlier sagas or tales approach to the credit of real history, and were unquestionably meant as such, though, as usual at an early period, debased by the intermixture of those *speciosa miracula* which the love of the wonderful early introduces into the annals of an infant country. There are, however, very many of the sagas, indeed by far the greater number of those now known to exist, which must be considered as falling rather under the class of fictitious than of real narratives; and which, therefore, belong to our present subject of inquiry. The *Omeyinger Saga*, the *Heimskringla*, the *Saga* of Olaf Triggvason, the *Eyrbyggia Saga*, and several others, may be considered as historical; whilst the numerous narratives referring to the history of the Nibelungen and Volsungen are as imaginary as the romances which treat of King Arthur and of Charlemagne. These singular compositions, short, abrupt, and concise in expression, full of bold and even extravagant metaphor, exhibiting many passages of forceful and rapid description, hold a character of their own; and whilst they remind us of the indomitable courage and patient endurance of the hardy Scandinavians, at once the honour and the terror of Europe, rise far above the tedious and creeping style which characterised the minstrel efforts of their successors, whether in France or England. In the pine forests also, and the frozen mountains of the north, there were nursed, amid the reliques of expiring paganism, many traditions of a character more wild and terrible than the fables of classical superstition; and these the gloomy imagination of the skalds failed not to transfer to their romantic tales. The late spirit of inquiry which has been so widely spread through Germany, has already begun to throw much light on this neglected storehouse of romantic lore, which is worthy of much more attention than has yet been bestowed upon it in Britain. It must, however, be remarked, that although the north possesses champions and romances of its own, unknown to southern song, yet, in a later age, the inhabitants of these countries borrowed from the French minstrels some of their most popular subjects; and hence we find sagas on the subject of Sir Tristrem, Sir Percival, Sir Ywain, and others, the well-known themes of French and English romance. These, however, must necessarily be considered later in date, as well as far inferior in interest, to the sagas of genuine northern birth. Mr. Ritson has indeed quoted their existence as depreciating the pretensions of the northern nations to the possession of poems of high antiquity of their own native growth. Had he been acquainted with the *Norman-Kiempe-Datur*, a large folio, printed at Stockholm in 1737, he would have been satisfied, that out of the numerous collection of legends respecting the achievements of Gothic champions, far the greater part are of genuine Norse origin; and although having many features in common with the romances of southern chivalry, are, in other marked particulars, distinctly divided from that class of fictitious composition.

German romance.

The country of Germany, lying contiguous to France, and constantly engaged in friendly and hostile intercourse with that great seat of romantic fiction, became, of course, an early partaker in the stores which it afforded. The Minnesingers of the Holy Empire were a race no less cherished than the Troubadours of Provence, or the Minstrels of Normandy; and no less active in availing themselves of their indigenous traditions, or importing those of other countries, in order to add to their stock of romantic fiction. Gotfrit of Strasburg composed many thousand lines upon the popular subject of Sir Tristrem; and others have been equally copious, both as translators and as original authors, upon various subjects connected with French romance; but Germany possessed materials, partly borrowed from Scandinavia, partly peculiar to her own traditional history, as well as to that of the Roman empire, which they applied to the construction of a cycle of heroes as famous

---

[1] *The Politicke and Militarie Discourses* of the Lord De La Nowe, pp. 87, 88. 4to. Lond. 1587.

in Teutonic song as those of Arthur and of Charlemagne in France and Britain.

As in all other cases of the kind, a real conqueror, the fame of whose exploits survived in tradition, was adopted as the central object, around whom were to be assembled a set of champions, and with whose history was to be interwoven the various feats of courage which they performed, and the adventures which they underwent. Theodorick King of the Goths, called in these romantic legends Diderick of Bern (*i. e.* Verona,) was selected for this purpose by the German Minnesingers. Among the principal personages introduced are Ezzel, King of the Huns, who is no other than the celebrated Attila; and Gunter, King of Burgundy, who is identified with a Guntacher of history who really held that kingdom. The good knight Wolfram von Eschenbach seems to have been the first who assembled the scattered traditions and minstrel tales concerning these sovereigns into one large volume of German verse, entitled *Heldenbuch*, or the Book of Heroes. In this the author has availed himself of the unlimited licence of a romancer; and has connected with the history of Diderick and his chivalry a number of detached legends which had certainly a separate and independent existence. Such is the tale of *Sigurd the Horny*, which has the appearance of having originally been a Norse saga. An analysis of this singular piece was published by Mr. Weber, in a work entitled *Illustrations of Northern Antiquities from the earlier Teutonic and Scandinavian Romances;* and the subject has been fully illustrated by the publications of the learned Von der Hagen in Germany, and those of the Hon. William Herbert.

It is here only necessary to say, that Theodorick, like Charlemagne and Arthur, is considered in the romance as a monarch more celebrated for the valorous achievements of the brotherhood of chivalry whom he has drawn around him, than for his own, though neither deficient in strength nor courage. His principal followers have each their discriminatory and peculiar attributes. Meister Hildebrand, the Nestor of the band, is, like the Maugis of Charlemagne's heroes, a magician as well as a champion. Hogan, or Hagan, begot betwixt a mortal and a sea-goblin, is the fierce Achilles of the confederation. It is the uniform custom of the romancers to conclude by a general and overwhelming catastrophe, which destroys the whole ring of chivalry whose feats they had commemorated. The ruin which Roncesvalles brought to the Paladins of Charlemagne, and the fatal battle of Camlan to the Knights of the Round Table, fell upon the warriors of Diderick through the revengeful treachery of Crimhilda, the wife of Ezzel; who, in revenge for the death of her first husband, and in her inordinate desire to possess the treasures of the Niflunga or Burgundians, brought destruction on all those celebrated champions. Mr. Weber observes that these German fictions differ from the romances of French chivalry, in the greater ferocity and less refinement of sentiment ascribed to the heroes; and also in their employing to a great extent the machinery of the Duergar, or dwarfs, a subterranean people to whom the *Heldenbuch* ascribes much strength and subtilty, as well as profound skill in the magic art, and who seem, to a certain extent, the predecessors of the European fairy.

Italian romance.

Italy, so long the seat of classical learning, and where that learning was first revived, seems never to have strongly embraced the taste for the Gothic romance. They received, indeed, the forms and institutions of chivalry, but the Italians seem to have been in a considerable degree strangers to its spirit, and not to have become deeply enamoured of its literature. There is an old romance of chivalry proper to Italy, called *Guerino the Wretched*, but we doubt if even this be of indigenous growth. Indeed, when they did adopt from the French the fashionable tales of Charlemagne and his Paladins, these did not attract the attention of the classical Italians, until Boiardo, Berni, Pulci, and, above all, the divine Ariosto, condescended to use them as the basis of their well-known romantic poems; and thus the fictitious narratives originally composed in metre, and afterwards rewritten in prose, were anew decorated with the honours of verse. The romantic poets of Italy did not even disdain to imitate the rambling, diffuse, and episodical style proper to the old romance; and Ariosto, in particular, although he torments the reader's attention, by digressing from one adventure to another, delights us, upon frequent perusals, by the extreme ingenuity with which he gathers up the broken ends of his narrative, and finally weaves them all handsomely together in the same piece. But the merits and faults of romantic poetry form themselves the fruitful subject of a long essay. We here only notice the origin of those celebrated works, as a species of composition arising out of the old romance, though surpassing it in regularity, as well as in all the beauties of style and diction.

Spani-
Portu
roman

With Spain the idea of romance was particularly connected; and the associations which are formed upon perusing the immortal work of Cervantes, induce us for a long time to believe that the country of Don Quixote must be the very cradle of romantic fiction. Yet, if we speak of priority of date, Spain was amongst the last nations in Europe with whom romance became popular. It was not indeed possible that, among a people speaking so noble and poetical a language, engaged in constant wars, which called forth at once their courage and their genius, there should not exist many historical and romantic ballads descriptive of their rencounters with the Moors. But their native poets seem to have been too much engaged with the events of their own age, and of that which had just preceded it, to permit of their seeking subjects in the regions of pure fiction; and we have not heard of a Spanish metrical romance, unless the poems describing the adventures of the Cid should be supposed to have any affinity to that class of composition. The Peninsula, however, though late in adopting the prevailing taste for romantic fiction, gave origin to one particular class, which was at least as popular as any which had preceded it. *Amadis de Gaul*, the production, it would seem, of Vasco de Lobeira, a Portuguese knight, who lived in the fourteenth century, gave a new turn to the tales of chivalry, and threw into the shade the French prose romances, which, until the appearance of this distinguished work, had been the most popular in Europe.

The author of *Amadis*, in order, perhaps, to facilitate the other changes which he introduced, and to avoid rushing against preconceived ideas of events or character, laid aside the worn-out features of Arthur and Charlemagne, and imagined to himself a new dynasty both of sovereigns and of heroes, to whom he ascribed a style of manners much more refined, and sentiments much more artificial, than had occurred to the authors of *Perceval* or *Perceforest*. Lobeira had also taste enough to perceive, that some unity of design would be a great improvement on the old romance, where one adventure is strung to another with little connection from the beginning to the end of the volume; which thus concluded, not because the plot was winded up, but because the author's invention, or the printer's patience, was exhausted. In the work of the Portuguese author, on the contrary, he proposes a certain end, to advance or retard which all the incidents of the work have direct reference. This is the marriage of Amadis with Oriana, against which a thousand difficulties are raised by rivals, giants, sorcerers, and all the race of evil powers unfavourable to chivalry; whilst these obstacles are removed by the valour of the hero, and constancy of the heroine, succoured on their part by those friendly sages, and blameless sorceresses, whose intervention gave so much alarm to the tender-conscienced De la Noue. Lobeira also displayed considerable attention to the pleasure which arises from the contrast of character;

and to relieve that of Amadis, who is the very essence of chivalrous constancy, he has introduced Don Galaor, his brother, a gay libertine in love, whose adventures form a contrast with those of his more serious relative. Above all, the *Amadis* displays an attention to the style and conversation of the piece, which, although its effects are now exaggerated and ridiculous, was doubtless at the time considered as the pitch of elegance; and here were, for the first time, introduced those hyperbolical compliments, and that inflated and complicated structure of language, the sense of which walks as in a masquerade.

The *Amadis* at first consisted only of four books, and in that limited shape may be considered as a very well conducted story; but additions were speedily made which extended the number to twenty-four; containing the history of Amadis subsequent to his obtaining possession of Oriana, and down to his death, as also of his numerous descendants. The theme was not yet exhausted; for, as the ancient romancers, when they commenced a new work, chose for their hero some newly invented Paladin of Charlemagne, or knight of King Arthur, so did their successors adopt a new descendant of the family of Amadis, whose genealogy was thus multiplied to a prodigious degree. For an account of *Esplandian, Florimond of Greece, Palmerin of England*, and the other romances of this class, the reader must be referred to the valuable labours of Mr. Southey, who has abridged both *Amadis* and *Palmerin*, with the most accurate attention to the style and manners of the original. The books of *Amadis* became so very popular, as to supersede the elder romances almost entirely, even at the court of France, where, according to La Noue, already quoted, they were introduced about the reign of Henry II. It was against the extravagance of these fictions in character and in style, that the satire of Cervantes was chiefly directed; and almost all the library of Don Quixote belongs to this class of romances, which, no doubt, his adventures contributed much to put out of fashion.

Fren Roma e.

In every point of view, France must be considered as the country in which chivalry and romance flourished in the highest perfection; and the originals of almost all the early romances, whether in prose or in verse, whether relating to the history of Arthur or of Charlemagne, are to be found in the French language; and other countries possess only translations from thence. This will not be so surprising when it is recollected, that these earlier romances were written, not only for the use of the French, but of the English themselves, among whom French was the prevailing language during the reigns of the Anglo-Norman monarchs. Indeed, it has been ingeniously supposed, and not without much apparent probability, that the fame of Arthur was taken by the French minstrels for the foundation of their stories in honour of the English kings, who reigned over the supposed dominions of that British hero; while, on the other hand, the minstrels who repaired to the coast of France, celebrated the prowess of Charlemagne and his twelve peers as a subject more gratifying to those who sat upon his throne. It is perhaps, some objection to this ingenious theory, that, as we have already seen, the battle of Hastings was opened by a minstrel, who sung the war-song of Roland, the nephew of Charlemagne; so that the Norman duke brought with him to England the tales that are supposed, at a much later date, to have been revived to soothe the national pride of the French minstrels.

How the French minstrels came originally by the traditional reliques concerning Arthur and Merlin, on which they wrought so long and so largely, must, we fear, always remain uncertain. From the Saxons we may conclude they had them not; for the Saxons were the very enemies against whom Arthur employed his good sword excalibar, that is to say, if there was such a man, or such a weapon. We know, indeed, that the British, like all the branches of the Celtic race, were much attached to poetry and music, which the numerous relics of ancient poetry in Wales, Ireland, and the Highlands of Scotland, sufficiently evince. Arthur, a name famous amongst them, with some traditions concerning the sage Merlin, may have floated either in Armorica, or among the half-British of the borders of Scotland, and of Cumberland; and thus preserved, may have reached the ear of the Norman minstrels, either in their newly conquered dominions, or through their neighbours of Brittany. A theme of this sort once discovered, and found acceptable to the popular ear, gave rise, of course, to a thousand imitations; and gradually drew around it a cloud of fiction which, embellished by such poetry as the minstrels could produce, arranged itself by degrees into a system of fabulous history, as the congregated vapours touched by the setting sun, assume the form of battlements and towers. We know that the history of Sir Tristrem, first versified by Thomas the Rhymer of Erceldoune, was derived from Welsh traditions, though told by a Saxon poet. In fact, it may be easily supposed, that the romancers of that early period were more eager to acquire popular subjects than delicately scrupulous of borrowing from their neighbours; and when the foundation-stone was once laid, each subsequent minstrel brought his contribution to the building. The idea of an association of knights assembled around one mighty sovereign, was so flattering to all the ruling princes of Europe, that almost all of them endeavoured to put themselves at the head of some similar institution, and the various orders of chivalry are to be traced to this origin. The historical foundation of this huge superstructure is almost imperceptible. Mr. Turner has shewn that the evidence rather inclines to prove the actual existence of King Arthur; and the names of Gawain, his nephew, and of Genuera, his faithful spouse, of Mordred, and Merlin, were preserved by Welsh tradition. To the same source may be referred the loves of Tristrem and Ysolde, which, although a separate story, has become, in the later romances, amalgamated with that of Arthur. But there can be little doubt that all beyond the bare names of the heroes owes its existence to the imagination of the romancers.

It might be thought that the romances referring to the feats of Charlemagne ought to contain more historical truth than those concerning Arthur; since the former relate to a well-known monarch and conqueror, the latter to a personage of a very doubtful and shadowy existence. But the romances concerning both are equally fabulous. Charles had, indeed, an officer named Roland, who was slain with other nobles in the field of Roncesvalles, fighting, not against the Saracens or Spaniards, but against the Gascons. This is the only point upon which the real history of Charlemagne coincides with that invented for him by romancers. Roland was prefect of Bretagne, and his memory was long preserved in the war-song which bore his name. A fabulous chronicler, calling himself Turpin, compiled, in or about the eleventh century, a romantic history of Charlemagne; but it may be doubted whether, in some instances, he has not availed himself of the fictions already devised by the early romancers, while to those who succeeded them his annals afforded matter for new figments. The personal character of Charlemagne has suffered considerably in the hands of the romantic authors, although they exaggerated his power and his victories. He is represented as fond of flattery, irritable in his temper, ungrateful for the services rendered him by his most worthy paladins, and a perpetual dupe to the treacherous artifices of Count Gam, or Ganelon, of Mayence; a renegade, to whom the romancers impute the defeat at Roncesvalles, and all the other misfortunes of the reign of Charles. This unfavourable view of the prince, although it may bear some features of royalty, neither resembles the real character of the conqueror of the Saxons and Lombards, nor can be easily reconciled with the idea, that he was introduced to flatter the personal vanity of the princes of the Valois race, by a portrait of their great predecessor.

The circumstance that Roland was a lieutenant of Brittany, and the certainty that Marie borrowed from that country the incidents out of which she composed her lays, seems to fortify the theory, that the French minstrels obtained from that country much of their most valuable materials; and that, after all that has been said and supposed, the history of Arthur probably reached them through the same channel.

The Latin writers of the middle ages afforded the French romancers the themes of those metrical legends which they have composed on subjects of classical fame.

The honour of the prose romances of chivalry, exclusive always of the books of Amadis, belongs entirely to the French, and the curious volumes which are now the object of so much research amongst collectors, are almost universally printed at Paris.

English romance.

England, so often conquered, yet fated to receive an accession of strength from each new subjugation, cannot boast much of ancient literature of any kind; and, in the department of which we treat, was totally inferior to France. The Saxons had, no doubt, romances (taking the word in its general acceptation); and Mr. Turner, to whose researches we are so much indebted, has given us the abridgment of one entitled *Caedmon,* in which the hero, whose adventures are told much after the manner of the ancient Norse Sagas, encounters, defeats, and finally slays an evil being called Grendel, who, except in his being subject to death, seems a creature of a supernatural description. But the literature of the Saxons was destroyed by the success of William the Conqueror, and the Norman knights and barons, among whom England was in a great measure divided, sought amusement, not in the lays of the vanquished, but in those composed in their own language. In this point of view, England, as a country, may lay claim to many of the French romances, which were written, indeed, in that language, but for the benefit of the court and nobles of England, by whom French was still spoken. When the two languages began to assimilate together, and to form the mixed dialect termed the Anglo-Norman, we have good authority for saying that it was easily applied to the purpose of romantic fiction, and recited in the presence of the nobility.

Robert de Brunne, who composed his *History of England* about this time, has this remarkable passage, which we give, along with the commentary of the editor of *Sir Tristrem,* as it is peculiarly illustrative of the subject we are inquiring into.

Als thai haf wryten and sayd,
Haf I alle in myn Inglis layd,
In symple speche as I couthe,
That is lightest in manne's mouthe.
I mad noght for no disours,
Ne for no seggours, no harpours,
Bot for the luf of symple men,
That strange Inglis cannot ken;
For many it ere that strange Inglis,
In ryme wate never what it is;
And bot thai wist what it mente,
Ellis methought it were alle schente.
I made it not for to be praysed,
Bot at the lewed men were aysed.
If it were made in ryme couwee,
Or in strangere, or enterlacé,
That rede Inglis it ere inowe
That couthe not haf coppled a kowe,
That outher in cowee or in baston
Sum suld haf ben fordon;
So that fele men that it herde
Suld not witte howe that it ferde.
I·see in song, in sedgeyng tale,
Of Erceldoun and of Kendale,
Non tham sayis as thai tham wroght,
And in ther saying it semes noght.
That may thou here in Sir Tristrem,
Over gestes it has the steem,
Over all that is or was,
If men it sayd as made Thomas.
Bot I here it no man so say,
That of some copple som is away.
So thare fayre saying here beforne,
Is thare travayle nere forlorne;
Thai sayd it for pride and nobleye,
That were not suylke as thei,
And alle that thai wild overwhere,
Alle that ilk wille now forfare.
Thai sayd it in so quainte Inglis,
That manyone wate not what it is.
Therfore heuyed wele the more
In strange ryme to travayle sore,
And my wit was oure thynne,
So strange speche to travayle in;
And forsoth I couth noght
So strange Inglis as thai wroght,
And men besoght me many a tyme
To turne it bot in light ryme.
Thai seyd, if I in strange ryme it turn,
To here it manyon suld skorne;
For in it ere names fulle selcouthe,
That ere not used now in mouthe.
And therfore, for the comonalté,
That blythely wild listen to me,
On light lange I it began,
For luf of the lewed man.

"This passage requires some commentary, as the sense has been generally mistaken. Robert de Brunne does not mean, as has been supposed, that the minstrels who repeated Thomas's romance of *Sir Tristrem,* disguised the meaning by putting it into *quainte Inglis;* but, on the contrary, that Kendal and Thomas of Erceldoune did themselves use such *quainte Inglis,* that those who repeated the story were unable to understand it, or to make it intelligible to their hearers. Above all, he complains that, by writing an intricate and complicated stanza, as '*ryme cowee, strangere,* or *entrelacé,*' it was difficult for the *diseurs* to recollect the poem; and of *Sir Tristrem,* in particular, he avers, that he never heard a perfect recital, because of some one '*copple*' or stanza, a part was always omitted. Hence he argues at length, that he himself, writing not for the minstrel or harper, nor to acquire personal fame, but solely to instruct the ignorant in the history of their country, does well in chusing a simple structure of verse, which they can retain correctly on their memory, and a style which is popular and easily understood. Besides which, he hints at the ridicule he might draw on his poem, should he introduce the uncouth names of his personages into a courtly or refined strain of verse. They were

Great names, but hard in verse to stand.

While he arrogates praise to himself for his choice, he excuses Thomas of Erceldoune and Kendale for using a more ambitious and ornate kind of poetry. They wrote, he says, for pride (fame) and for nobles, not such as these my ignorant hearers."[1]

If the editor of *Sir Tristrem* be correct in his commentary, there existed in the time of Robert de Brunne, minstrels or poets who composed English poetry to be recited in the presence of the great, and who, for that purpose, used a singularly difficult stanza, which was very apt to be mutilated in recitation. *Sir Tristrem,* even as it now exists, shows likewise that considerable art was resorted to in constructing the stanza, and has, from beginning to end, a concise, quaint, abstract turn of expression, more like the Saxon poetry, than the simple, bald, and diffuse details of the French minstrel. Besides *Sir Tristrem,* there remain, we conceive, at least two other examples of "gestes written in quainte Inglis" composed, namely, according to fixed and complicated rules of verse, and with much attention to the language, though the effect produced is far from pleasing. They are both of Scottish origin, which may be explained, by recollecting, that in the Saxon provinces of Scotland, as well as at the court, Norman was never generally used; and therefore it is probable that the English language was more cultivated in that country at an early period, than in England itself, where, among the higher orders, it was for a long time superseded by that of the French conquerors. These romances, entitled *Sir Gawain*, and *Sir Gologras*, and *Sir Galeran of Galloway*, have all the appearance of being original compositions, and display considerable poetical effort. But the uncouth use of words dragged in for the sake of alliteration, and used in secondary and oblique meanings, renders them extremely harsh in construction, as well as obscure in meaning.

---

[1] *Sir Tristrem,* Introduction, pp. 61–65. Edin. 1804.

In England it would seem that the difficulties pointed out by De Brunne, early threw out of fashion this ornate kind of composition; and the English minstrels had no readier resource than translating from the French, who supplied their language at the same time with the phrases of chivalry which did not exist in English. These compositions presented many facilities to the minstrel. He could, if possessed of the slightest invention, add to them at pleasure, and they might as easily be abridged when memory failed, or occasion required. Accordingly, translations from the French fill up the list of English romance. They are generally written in short lines rhyming together; though often, by way of variety, the third and sixth lines are made to rhyme together, and the poem is thus divided into stanzas of three couplets each. In almost all of these legends, reference is made to "the romance," that is, some composition in the French language, as to the original authority. Nay, which is very singular, tales where the subjects appear to be of English growth, seem to have yet existed in French ere they were translated into the language of the country to which the heroes belonged. This seems to have been the case with *Hornchild*, with *Guy of Warwick*, with *Bevis of Hampton*, all of which appear to belong originally to England; yet are their earliest histories found in the French language, or at least the vernacular versions refer to such for their authority. Even the romance of *Richard*, England's own Cœur de Lion, has perpetual references to the French original from which it was translated. It must naturally be supposed that these translations were inferior to the originals; and whether it was owing to this cause, or that the composition of these rhymes was attended with too much facility, and so fell into the hands of very inferior composers, it is certain, and is proved by the highest authority, that of Chaucer himself, that even in his time these rhyming romances had fallen into great contempt. The *Rime of Sir Thopas*, which that poet introduces as a parody, undoubtedly, of the rhythmical romances of the age, is interrupted by mine host Harry Bailly, with the strongest and most energetic expressions of total and absolute contempt. But though the minstrels were censured by De Brunne, for lack of skill and memory, and the poems which they recited were branded as "drafty rhymings," by the far more formidable censure of Chaucer, their acceptation with the public in general must have been favourable, since, besides many unpublished volumes, the two publications of Ritson and Weber bear evidence of their populatity. Some original compositions doubtless occur among so many translations, but they are not numeroes, and few have been preserved. The poem of *Sir Eger* and *Sir Greme*, which seems of Scottish origin, has no French original; nor has any been discovered either of the *Squire of Low Degree*, *Sir Eglamour*, *Sir Pleindamour*, or some others. But the French derivation of the two last names renders it probable that such may exist.

The minstrels and their compositions seem to have fallen into utter contempt about the time of Henry VIII. There is a piteous picture of their condition in the person of Richard Sheale, which it is impossible to read without compassion, if we consider that he was the preserver at least, if not the author of the celebrated heroic ballad of *Chevy Chace*, at which Sir Philip Sidney's heart was wont to beat as at the sound of a trumpet. This luckless minstrel had been robbed on Dunsmore Heath, and, shame to tell, he was unable to persuade the public that a son of the Muses had ever been possessed of the sixty pounds which he averred he had lost on the occasion. The account he gives of the effect upon his spirits is melancholy, and yet ridiculous enough.

> After my robbery my memory was so decayde,
> That I colde neather syng, nor talke, my wytts wer so dismayde,
> My audacitie was gone, and all my myrry tawk:
> Ther ys sum heare have sene me as myrry as a hawke;
> But nowe I am so trublyde with phansis in my mynde,
> That I cannot play the myrry knave, accordyng to my kynd.
> Yet to tak thought, I perseve, ys not the next waye
> To bring me out of det, my creditors to paye.
> I may well say that I hade but well hape,
> For to lose about threscore pounde at a clape.
> The losse of my mony did not greve me so sore,
> But the talke of the pyple dyde greve me moch mor.
> Sum sayde I was not robde, I was but a lyeng knave,
> Yt was not possyble for a mynstrell so much mony to have.
> In dede, to say the truthe, that ys ryght well knowene,
> That I never had so moche mony of myn owene,
> But I had frendds in London, whos namys I can declare,
> That at all tyms wold lende me cc.lds. worth of ware,
> And sum agayn such frendship I founde,
> That thei wold lend me in mony nyn or tene pownde.
> The occasion why I cam in dete I shall make relacion,
> My wyff in dede ys a sylk woman be her occupacion,
> And lynen cloths most chefly was her greatyste trayd,
> And at faris and merkytts she solde sale-ware that she made;
> As shertts, smockys, partlytts, hede clothes, and othar thinggs,
> As sylk thredd, and eggyngs, skirrts, bandds, and strings.
>
> From *The Chant* of Richard Sheale,
> *British Bibliographer*, No. xiii. p. 101.

Elsewhere, Sheale hints that he had trusted to his harp, and to the well known poverty attached to those who used that instrument, to bear him safe through Dunsmore Heath. At length the order of English minstrels was formally put down by the act 39th of Queen Elizabeth, classing them with sturdy beggars and vagabonds; in which disgraceful fellowship they only existed in the capacity of fiddlers, who accompanied their instrument with their voice. Such a character is introduced in the play of *Monsieur Thomas*, as the "poor fiddler who says his songs." The metrical romances which they recited also fell into disrepute, though some of the more popular, sadly abridged and adulterated, continued to be published in *chap. books*, as they are called. About fifty or sixty years since, a person acquired the nickname of *Rosewal and Lilian*, from singing that romance about the streets of Edinburgh, which is probably the very last instance of the proper minstrel craft.

If the metrical romances of England can boast of few original compositions, they can show yet fewer examples of the prose romance. Sir Thomas Malory, indeed, compiled, from various French authorities, his celebrated *Morte d'Arthur*, indisputably the best prose romance the language can boast. There is also *Arthur of Little Britain;* and the Lord Berners compiled the romance of the *Knight of the Swan*. The books of Amadis were likewise translated into English; but it may be doubted whether the country in general ever took that deep interest in the perusal of these records of love and honour with which they were greeted in France. Their number was fewer; and the attention paid to them in a country where great political questions began to be agitated, was much less than when the feudal system still continued in its full vigour.

III. We should now say something on those various kinds of romantic fictions which succeeded to the romance of chivalry. But we can only notice briefly works which have long slumbered in oblivion, and which certainly are not worthy to have their slumbers disturbed.

Pastoral romance.

Even in the time of Cervantes, the pastoral romance, founded upon the *Diana* of George of Monte Mayor, was prevailing to such an extent as made it worthy of his satire. It was, indeed, a system still more remote from common sense and reality than that of chivalry itself. For the maxims of chivalry, high-strained and absurd as they are, did actually influence living beings, and even the fate of kingdoms. If *Amadis de Gaul* was a fiction, the Chevalier Bayard was a real person. But the existence of an Arcadia, a pastoral region, in which a certain fantastic sort of personages, desperately in love, and thinking of nothing else but their mistresses, played upon pipes, and wrote sonnets from morning to night, yet were supposed all the while to be tending their flocks, was too monstrously absurd to be long credited or tolerated.

Heroic romances.

A numerous, and once most popular class of fictions, was that entitled the heroic romance of the seventeenth century.

If the ancient romance of chivalry has a right to be called the parent of those select and beautiful fictions which the genius of the Italian poets has enriched with such peculiar charms, another of its direct descendants, the heroic romance of the seventeenth century, is, with few exceptions, the most dull and tedious species of composition that ever obtained temporary popularity. The old romance of Heliodorus, entitled *Theagenes and Chariclea*, supplied perhaps the earliest model of this style of composition; but it was from the romances of chivalry that it derives its most peculiar characteristics. A man of a fantastic imagination, Honoré d'Urfé, led the way in this style of composition. Being willing to record certain love intrigues of a complicated nature which had taken place in his own family, and among his friends, he imagined to himself a species of Arcadia on the banks of the Lignon, who live for love, and for love alone. There are two principal stories, said to represent the family history of D'Urfé and his brother, with about thirty episodes, in which the gallantries and intrigues of Henry IV.'s court are presented under borrowed names. Considered by itself, this is but an example of the pastoral romance; but it was so popular that three celebrated French authors, Gomberville, Calprenede, and Madame Scuderi, seized the pen, and composed in emulation many interminable folios of heroic romance. In these insipid performances, a conventional character, and a set of family manners and features, are ascribed to the heroes and heroines, although selected from distant ages, and various quarters of the world. The heroines are, without exception, models of beauty and perfection; and, so well persuaded of it themselves, that to approach them with the most humble declaration of love, was a crime sufficient to deserve the penalty of banishment from their presence; and it is well if the doom were softened to the audacious lover, by permission, or command to live, without which, absence and death were to be accounted synonymous. On the other hand, the heroes, whatever kingdoms they have to govern, or other earthly duties to perform, live through these folios for love alone; and the most extraordinary revolutions which can agitate the world, are ascribed to the charms of a Mandana, or a Statira, acting upon the crazy understanding of their lovers. Nothing can be so uninteresting as the frigid extravagance with which these lovers express their passion; or, in their own phrase, nothing can be more freezing than their flames, more creeping than their flights of love. Yet the line of metaphysical gallantry which they exhibited, had its date, and a long one, both in France and England. In the latter country they continued to be read by our grandmothers during the Augustan age of English; and while Addison was amusing the world with his wit, and Pope by his poetry, the ladies were reading Clelia, Cleopatra, and the Grand Cyrus. The fashion did not decay till about the reign of George I.; and even more lately, Mrs. Lennox, patronized by Dr. Johnson, wrote a very good imitation of Cervantes, entitled *The Female Quixote*, which had those works for its basis. They are now totally forgotten. (D. D. D.)

MODERN ROMANCE AND NOVEL.

We alluded in the commencement of this essay, to the division of fictitious narratives in prose, into two classes; the *romance*, in which the interest of the narrative turns chiefly on marvellous and uncommon incidents; and the *novel*, in which the events are accommodated to the ordinary train of human events, and the modern state of society.

Rise of novel writing in England.

The rise of this last department of fictitious composition in England, takes place about the commencement of the eighteenth century; and its coincidence with the decline of the drama is remarkable. The novel aspired, in fact, to perform for a reading and refined age, what the drama had done for a ruder and more excitable period; to embody the spirit of the times in pictures at once amusing and accurate, and in the form best calculated to awaken attention and interest in those to whom they are addressed. In the earlier periods of a national literature, while the poetical and imaginative spirit of the time takes the direction of the long prose romance, the task of painting manners, and satirizing follies, and displaying the comic oddities of character, is most efficiently performed by the drama. Its strength, terseness, and brevity, with the aid of action and scenery, present the manners living as they rise, with abundance of force at least, and probably, for a time, with sufficient fidelity. But as society becomes more decorous, and peculiarities of manners less marked, the pictures exhibited by the stage are apt to become less true; for dramatic effect appears to demand something more stimulating than reality affords; and hence the drama, with a pardonable leaning to the principle of stage effect, often continues to reproduce the manners, vices, and humours of a preceding age, long after they have ceased to exist, merely because they are found better adapted to that broad and strongly-coloured delineation in which it chiefly deals. Thus, though the age of Vanburgh, Congreve, and Wycherley, was probably not a very moral age, and the tone even of its polite conversation, would probably appear somewhat questionable to modern ears, there seems to be no reason to believe that the universal profligacy of manners, and boundless licence of conversation which are exhibited in the comedies of these writers, really characterised the period at which they wrote. Their Wildairs, Sir John Brutes, Lady Touchwoods, and Mrs. Frails, are conventional reproductions of those wild gallants and demireps which figure in the licentious dramas of Dryden and Shadwell. They represented the manners and the morals of an age gone by; and the audiences who tolerated these indecencies for the sake of the wit by which they were occasionally redeemed, would have been revolted by their exaggeration and incorrectness, if they had looked upon them as exhibitions of society as it existed. The drama, then, had ceased to be the mirror in which the age could contemplate itself, and exhibited the license of a masque, or the extravagance of a caricature, much more than the sobriety of actual life, or the fidelity of a portrait. Besides, there are many lesser traits of character, many sentiments and feelings, which are not at all dramatic, and which had therefore been overlooked by writers for the stage, yet in themselves highly interesting and curious, and capable, when judiciously employed, of exercising a strong influence on the feelings. These become more prominent, and stand out in brighter relief, as the restraints of civilization gradu-

The novel a substitute for the drama.

ally throw into the background the wilder passions and more stormy impulses of our nature, until they acquire an importance which not only justifies, but renders their introduction into any fictitious narrative which represents the peculiarities of the time, necessary; and for this purpose, the calm and even march of the novel, and the detailed development both of sentiment and incident which it allows, is found to be admirably adapted. It is in the works of our novelists, therefore, rather than our dramatists, and in those passages in our essayists of Queen Anne's time, in which they treat of past fashions, manners, whims, and humours, that we must look for the changes which society has undergone, and from which we must try to realize to ourselves the features which it exhibited at any particular period.

Fie of the vel wid than the ama.

The novel, then, affords a wider field for accurate and complete delineation of passions and feelings than the drama, and certainly one more in harmony with the dispositions of a modern public. In powerful effects no doubt it cannot compete with the stage. The whole range of novel or romance contains nothing, for instance, which in its tremendous impression, can be compared with the explosion of passion in the third act of Othello; but, on the other hand, it has greatly the advantage in the impression of verisimilitude which it leaves behind, produced by the accumulation of many particulars and minute traits of character; in pleasing interchanges of action and repose; in the delineation of emotions, which the drama, speaking only to the eye and the ear, cannot lay before us; in the descriptions of external scenery, which, in the hand of a writer of genius, are far more effective, when presented in words to the imagination, than when counterfeited to the eye upon the stage, even by all the united resources of the scene-painter and the mechanist; and which, from the strong connection which exists between the state of our feelings and external influences, are found in the hands of a judicious novelist, to afford powerful materials for deepening the pervading tone of sentiment which he aims to produce; just as in painting relief and effect are obtained by the tone and character of the background against which the figures are opposed. Another advantage obtained by the substitution of narrative fiction for the drama, was, that a much wider licence was obtained in the conduct of the plot. A good plot is no doubt as essential to the novel as the drama; but the kind of plot which may be used with effect in each, and the manner in which the incidents are to be conducted, differ materially. A play in which every scene does not grow out of the preceding, and lead directly into the next, with a visible progress of plot, is in that respect faulty. On the contrary, in the novel and romance, as in real life, much is admissible which is episodical, which does not directly help forward nor produce the catastrophe, but merely tends to bring out some point of character in the personages represented, or to increase the air of verisimilitude in the main story, by the appearance of minute and literal correctness in the details. In the novel or romance, too, it has been generally remarked that the catastrophe may be made to turn upon accident, but that this is inadmissible in the drama.[1] Thus the catastrophe in the *Bride of Lammermoor*, where Ravenswood is swallowed up by a quicksand, is singularly grand in romance, but would be inadmissible in a drama. And on the same principle, Schiller has, in his *Fiesco*, thought himself compelled to deviate from the actual truth of history, and to ascribe the Count's death, not to an accidental stumble from a plank, but to the hand of the republican Verrina. In a novel, the real catastrophe would have been far more impressive in its moral effect than the imaginary one; but Schiller held, and we think rightly, that in the drama nothing must be *accident*, but every thing *result.*

Blendin f the ovel an omance

Although, as compared with the romance, the term novel may be said to indicate a class of fictions dealing more with calm feelings, and with manners and humours, than with strong passions, and deriving its interest more from the probability than the marvellous nature of its incidents, this definition is not to be taken too literally; for there are many works which we might call novels, in as much as the scene is laid in modern times, and the general course of the incidents is that of every-day life, but in which the even tenor of the story is occasionally broken by scenes of powerful passion, or incidents of a mysterious and terrible character, elevating the composition for the time into the sphere of the romantic; so that perhaps the word tale, as a middle term between the others, would most appropriately describe them. It has been doubted whether, although such a union of the common-place with the extraordinary, be not unfrequently met with in the course of real life, a more cautious separation of these elements would not, on the whole, be most favourable to the effect of a narrative as a work of art; and whether the attempt to blend them, does not produce in fiction, something of that illegitimate effect which is the result of the melo-drama on the stage. It is certain, however, that the tendency for some time past, and particularly since the school of fiction introduced by Sir Walter Scott, has been towards a mixture of the novel and romance in the same composition, so that broad comedy is often found alternating with the pathetic, the gaiety of a ball-room with midnight murders upon lonely heaths, and the disclosure of some piece of fashionable scandal standing side by side with the discovery of some secret and fearful crime. In the hands of our great masters of fiction, we admit the fine effect which these occasionally produce. Judiciously arranged, these opposites are the light and shadow of the composition; but even in our greatest modern novelist, we could point out not a few instances in which this sort of contrast is carried too far; while in many of his imitators, it is so regularly and mechanically introduced, that, as in the case of Mr. Puff's stage arrangements, we can always predict that the discharge of cannon will be followed by soft music.

Mrs. Behn

Mrs. Heywood.

When the declining popularity of the pastoral and heroic romance of the seventeenth century, suggested the necessity of opening a new vein in fiction, it is probable that the stilted, unnatural, and exaggerated character of those effete compositions led the public taste, by a natural recoil of feeling, into the opposite extreme, viz. the selection of topics and characters from common, and even from vulgar life, and a literal adherence to nature, even at the risk of the sacrifice of art. For we pass over the tiresome and licentious love stories of Mrs. Aphra Behn, with the just remark of Sir Richard Steele, that the lady appears to have "understood the practical part of love better than the speculative," as well as those of her imitator, Mrs. Heywood, in which the struggle between the high sentimental character of the heroic romance, and the growing taste for a style of portraiture more true to the life, is very obvious, and come at once to the writer by whom the inspiration of reality was carried to its greatest perfection.

Defoe.

Defoe, (1661—1731) without high imagination, with no power of raising the passions, with little pathos and no eloquence, had yet that peculiar genius which enabled him to excel within the peculiar department which he chose for himself; that of counterfeiting homely truth by fiction, and forging, as it were, the handwriting of nature herself, with a dexterity which defied detection. Whether Defoe was led to the selection of his peculiar themes, by a real sympathy with roguery, (and his conduct in regard to the well-known imposture of Mrs. Veal's Ghost would justify us in believing him to be like Gil Blas, "tant soi peu fripon;") or by the influence of the Spanish romances of roguery, such as Lazaro de Tormes, Marcos de Obregon, and Gusman d'Alfarache, with some of which it is highly probable that he was acquainted through translations; or whether his strong vulgar likenesses of seafaring personages, half privateer, half mariner, and his fondness for the delineation of equivocal characters of all kinds, arose from his familiarity with the one class, through his residence at Limehouse, and his acquaintance with Dampier,—and with the other, from his long and frequent imprisonments;—it is certain that though he had no intention of favouring immorality, he yet enters upon the delineation of personages, and scenes of roguery, low profligacy and vice, with a degree of curiosity and complacency, and dwells upon them with a fondness and minuteness of detail, altogether uncommon, and not a little unaccountable in a person who in his opinions savoured of the puritan. This strange labour of love, and study of the morbid anatomy of society, has resulted in a series of night pieces from the haunts of crime, which, though sombre and gloomy in a high degree, and little suited to a cultivated taste, nay, indeed, frequently producing on the mind the painful effect of a real chapter from the *Newgate Calendar*, yet display the most wonderful invention and keeping in all their parts, and a coherence and dexterity of adaptation to each other, which render the ordinary tests by which we endeavour to discriminate a fictitious from a real narrative, inadequate or altogether inapplicable to these singular compositions of Defoe. Whatever might be the motive of his humility of choice, Defoe, like many of his favourite heroes, was perfectly contented to take up his abode in the back settlements of fiction, and was most at home in that Alsatia of Romance, the purlieus of which, by common consent, his more ambitious predecessors had sedulously avoided, as discreditable or dangerous. The transition from their refined Orondates' and Statiras', to the society of the *Captain Jack* and *Moll Flanders* of Defoe, is, to use a phrase of Sterne, like turning from Alexander the Great to Alexander the coppersmith. In his novels, we rarely meet with any thing more exalted or respectable, than masters of trading vessels, dealers in small wares, supercargoes, or, it may be, pickpockets, pirates, candidates for the plantations, or *emeriti* who have already obtained that distinction. In the foreground, we have the cabin, the night cellar, the haunts of fraud, or the round-house; in the distance, Newgate, or Execution Dock. There can be but one opinion, however, as to the wonderful air of veracity, resembling that of a deposition upon oath, which Defoe has imparted to his fictitious creations, and which his genius effects, mainly by accumulation of details, *non vi sed sæpe cadendo;* often even by the introduction of a multitude of irrelevant particulars and repetitions, just as in the conversation of uneducated persons in real life. Accordingly the result, as a simulacrum of reality, is one of magical deception. Lord Chatham, it is well known, took his *Memoirs of a Cavalier* for a real history; Dr. Mead believed his *Journal of the Plague* to be the work of a medical man, and his impudent but most plausible history of the apparition of Mrs. Veal, being received by many sober-minded persons as an actual apocalypse from the spiritual world, was the means, as is well known, of disposing of an unsaleable edition of Drelincourt upon death.

[1] See some valuable papers on Art in Fiction, ascribed, we believe with justice, to Sir L. Bulwer. *Monthly Chronicle*, Nos. i. and ii.

Robinson Crusoe.

But notwithstanding this peculiar power of stamping the impression of reality upon the coinage of his imagination, which, to say the truth, was seldom of the finest metals, it may be safely affirmed, that but for his *Robinson Crusoe*, Defoe would scarcely now be remembered as a writer of fiction. The charm of that work, the first part of which appeared in 1719, is, that it emancipates us from those low haunts and questionable society with which his other novels make us acquainted. We escape from the fumes of tobacco and strong waters, to breathe a purer air on that lone island placed far amidst the melancholy main, where he has imprisoned his shipwrecked mariner; and while Defoe's unrivalled power of inventing a series of probable minutiæ, both in the way of reflexion and incident, enables him to conduct with consummate skill, what we may call the self-education of Crusoe in his solitude,—the process by which he adapts himself to his situation, and the gradual triumphs which, by his ingenuity and patience, he obtains over the difficulties and privations by which he is surrounded, till he changes desolation into comfort;—the imagination of the writer is visibly raised beyond its usual grovelling level by the romance of the situation which he describes. His genius imbibes the spirit of the place; it imparts to the cave of the sailor, something of the seclusion and purity of a hermitage; till the simple train of reflections which he puts into the mouth of his uneducated mariner, upon the sublimity and awfulness of solitude, impress the mind more than the most eloquent declamation. It is a fine proof how completely Defoe has succeeded in interesting us for the solitary being to whom he has given a poetical life, and attuned the mind of his readers to that sentiment of silence and unbroken repose which is breathed over the scene of his imprisonment,—"where all the air a solemn stillness holds,"—that after a time the least incident which threatens to disturb the security of the cave, or the solitude of the island, assumes importance in our eyes, and the groan of an old goat expiring in a cave, or the print of a man's foot in the sand, awaken a feeling of suspense and anxiety which many a writer has in vain laboured to excite by a prodigal expenditure of the machinery of terror.

That *Robinson Crusoe* may be considered in a great measure as a fortunate accident, and that its main charm arises from the more poetical and refined character which the nature of the story and its locality almost necessarily impressed upon it, is indeed evident from the visible inferiority of the second part, where the seclusion of the scene is broken in upon, and Defoe peoples the island with his usual retinue of planters and ship's captains; a production which scarcely rises above the level of his *Captain Singleton*.

The application of the same principle of producing effect by minuteness of detail rather than by grasp, or the selection of a few marking traits, is visible in our next great novelist, Richardson (1689–1761,) but the principle is applied in a different and higher way. Defoe was satisfied with weaving chains of probable incidents, which might be fitted to any character, or at least any character of a given class, such as a mariner or a merchant, a planter or a pickpocket. He did not care, at all events he did not labour, to individualize character. Crusoe, his most finished portrait, is still only the average representative of all shipwrecked mariners; his reflections and his struggles, embody the hopes, fears, and efforts, of all men left to maintain a solitary warfare with difficulties. So his Captain Jack, born a gentleman and bred a pickpocket, has nothing to separate him from other *enfans perdus* of the same class. But Richardson aspired to the creation rather of probable character than probable incident; and to this he applied the same system of accumulating minute traits of words, thoughts, and actions, and reiterating small touches, and minute lights and shadings, which Defoe had done to the creation of masses of coherent and plausible events. In the latter department, indeed, he is probably neither remarkable for success nor failure. Occasionally, and particularly in his *Sir Charles Grandison*, he outrages both patience and probability in no inconsiderable degree; and so little progress does the narrative make, that as Johnson remarked to Erskine, "Were you to read Richardson for the story, your impatience would be so fretted, you would go hang yourself." But even in the most successful portion of his plots, there is no chance of our mistaking fiction for fact; the artist does not disappear behind his creations as in the case of Defoe. The very form, too, in which his novels are cast, that of a series of correspondence, however favourable to the display of traits of character, and minute dissection of sentiment, is almost in itself fatal to the vraisemblance of incident. The affairs of private life we cannot help recollecting, are seldom managed to any great extent through the post-office, while in many cases it remains a mystery how such matters came to be committed to paper at all, and least of all under the circumstances in which they are supposed to be recorded by these persevering, and, in the existing state of the revenue laws, formidable correspondents.

There is in the mind of Richardson a very remarkable union of feminine tastes with masculine vigour. Early accustomed peculiarly to court the society of females; the depository of their gossip, the confident of their love secrets, the complete letter-writer of a little knot of young ladies when only thirteen years of age, the deference which he thus acquired for their tastes, and the insight he obtained into their habits of thinking, though probably springing, as Johnson believed, very much from his own vanity and love of praise, appear to have been of the utmost use to him in his novels, in which so much of the interest rests upon the female characters, and in the minute dissection and study of emotions and sentiments in which women are either the chief actors or sufferers. The traces of this influence appear constantly, and sometimes in excess, in the minute accuracy with which he dwells, in description, upon those little particulars of looks, and voice, and gesture, and turns of speech, which men in their correspondence generally overlook, but which women note with such care, and interpret with such sagacity; in the complacency with which he dwells on the details of robes and wedding dresses, which are conceived in the spirit of a waiting-woman, and executed with the learning of a man-milliner; and which, as in the minute description given by Lovelace of Clarissas' dress at the time of her elopement, are occasionally introduced in the worst place.

The more favourable results of these tastes are exhibited in the wonderful familiarity he evinces with the feelings and sympathies of women; for though, in his notions of perfection, either in manners or morals, we of another age often see cause to depart from Richardson's standard, we may trust implicitly to his accuracy, when he is delineating the movements of passion in the female breast, the revolutions of feeling, or the struggle between feeling and delicacy. In his female portraits even more than in his corresponding delineations of male character, we acknowledge the justice of the remark which Sir Walter Scott applies to his portraits generally, that "in his survey of the heart, he left neither head, bay, nor inlet behind him, until he had traced its soundings, and laid it down in his chart with all its minute sinuosities, its depths, and its shallows." This accuracy, indeed, constitutes at once his strength and his weakness; for not content with having surveyed the coast and taken its bearings, he still, from the very pride of discovery, insists on following the windings of the shore, and pointing out its landmarks, when those on board would have gladly seen him make his passage by the shortest course. It was the misfortune of Richardson, that, like nervous men in company, or like painters who go on retouching till the picture becomes loaded, he never knew when to have done, either with a character or a conversation. He was unskilful, as D'Israeli remarks, in the art of writing, and "could never lay his pen down while his inkhorn supplied it." Even as regards the description of sentiment, or the creation of characteristic dialogue, the field in which Richardson was most at home, it is certain that he carried his system, probably as much from this inability to leave off, as from choice, to extremes, particularly in his last novel, *Sir C. Grandison;* and unless the reader selects that work on the system of the old lady mentioned by Sir Walter Scott, who chose it because she could sleep for half an hour at any time during its perusal, and still find the personages just where she left them, conversing in the cedar parlour, he will probably think there is more justice than D'Israeli seems willing to admit in the cold remark of D'Alembert, "*La nature est bonne a imiter, mais non pas jusqu' a l'ennui.*"

It is not often that with this feminine character of intellect, a masculine vigour in painting scenes of a passionate and terrible cast is found united, and yet Richardson has proved his mastery over the higher passions, not less than his minute study of sentiment and manners, in the conclusion of *Clarissa Harlowe.* To apply to him the epithet of the Shakspeare of prose fiction, which has been done by D'Israeli, is extravagant. A solitary creation of this kind, highly pathetic and morally impressive as it is, is but a narrow basis on which to rest the claims of the novelist to such a title. But the conception of the noble character of Clarissa Harlowe, set off by such a foil as is afforded by that of Lovelace, perhaps the most finished picture of the self-possessed and insinuating libertine ever drawn, (and certainly as great an improvement on that of the Lothario from which it was drawn, as Rowes' hero had been on the vulgar rake of Massinger,) and the closing scenes of that novel, are at all events sufficient to place Richardson *among* the great writers of fiction; among the few who have formed a striking and original conception, which they have wrought out with a corresponding felicity and power. It is not the common-place idea of a woman of virtue foiling the schemes of a seducer, which Richardson has undertaken to illustrate: in the case of a lady like Clarissa, of birth, education, and good feelings, Mrs. Barbauld says truly, that would have been no triumph worthy of being recorded by such a pen; but it is the dignity, the deep interest, he has lent to the character, even in that situation of personal dishonour, with which, from whatever cause it has arisen, we are apt to connect the idea of degradation. "There is something," says Mrs. Barbauld,[1] "in virgin purity, to which the imagination willingly pays homage. In all ages something saintly has been attached to the idea of unblemished chastity, but it was reserved for Richardson to overcome all circumstances of dishonour and disgrace, and to throw a splendour round the violated virgin more radiant than she possessed in her first bloom. He has drawn the triumph of mental chastity; he has drawn it uncontaminated, untarnished, and incapable of mingling with pollution."

Clarissa Harlowe.

Pamela.

The other novels of Richardson, *Pamela,* and *Sir Charles Grandison,* are of an inferior order to *Clarissa. Pamela,* his first work, besides the questionable character of some of its highly coloured scenes, the license of which leads one to smile at the notions of morality entertained by that literary oracle who declared, "that if all other books were to be burned, Pamela and the Bible should be preserved," is justly liable to the objections pointed out by Mrs. Barbauld, that the heroine throughout her probation seems guided as much by worldly wisdom as by the love of virtue; that she acts like one who knows her price, and that her purity is protected more by the chance of securing a rich husband, and the prospect of "the gilded coach and dappled Flanders mares," which she sees in perspective, than by any idea that virtue is its own reward.

Sir Charles Grandison.

Least of all, is it possible to relish *Sir Charles Grandison,* a work written upon an entirely wrong plan; a system of pedantic morality put in action in the person of a formal, bowing, moralizing hero, "content to dwell in decencies for ever;" a hero whose worst trial, as Sir Walter Scott observes, is the embarrassment of choosing between two females, both handsome, accomplished, and in love with him; a gentleman who detests the theory of duelling on Christian principles, but reconciles the practice of it to his conscience, because his skill in swordsmanship always enables him to disarm his adversary without endangering the life of either; a principle which makes the morality not less than the prudence of fighting to depend upon a man's cunning of fence.

---

[1] Richardson's *Life and Correspondence,* vol. i. Introduction.

Fielding.

Tom Jones

A strong contrast to the subtlety, the fine perception, and the power over the passions evinced by Richardson, is presented by his rival Fielding, (1707–1754,) who, with no command of the pathetic, no great share of wit, and no taste for that minute analysis of sentiment and wire-drawing of description in which our English Marivaux indulges, has yet maintained a more general and permanent popularity, by a combination of qualities well suited for the purpose. His grasp of observation led him to select with unerring sagacity, the leading traits of ordinary character, and to epitomize nature with skill, instead of transcribing her at full length. His field of delineation admits of such variety and contrast, that in fact it excludes none but the highest and most poetical elements, in which Fielding had neither power of observation or conception. His flow of animal spirits and healthy vivacity of manner, contrast strangely with the Dutch finishing of Richardson's pencilling, but are as well suited to the active, out-of-door scenes which Fielding loved to draw, in his pictures of imbroglios at ale-houses, and the stirring life of the road, as the pains-taking inventories of Richardson were to his still-life interiors, and the drowsy monotony of the occupations of their inhabitants. To these he added, at least in his great work, *Tom Jones*, the charm of a plot of unrivalled skill, in which the complex threads of interest are all brought to bear upon the catastrophe in a manner equally unexpected and simple, a grave humour, and power of quiet satire unmixed with caricature, in which he is equally superior to Richardson and to Smollett. And with his other requisites he combined a knowledge of English life, both in its better features and its deformities, by which we mean, of the essential qualities of men, as modified at that time by the accidents of situation, education, and pursuits,—the result, perhaps, of a long, and not always reputable experience,—to which Richardson, surrounded by a circle of female gossips, and weaving out his materials in his quiet back shop, purely from the stores of his imagination, can make but slender pretension.

Amelia.

Amelia, much as it was admired by Johnson, is greatly inferior to *Tom Jones*. If the tone of the latter be far from high, that of *Amelia* is creeping and vulgar in no ordinary degree. Booth has Jones' vices with an additional shade of meanness. Half the plot turns on the embarrassments of debt and contrivances to make both ends meet; and one or other of the characters is generally in a spunging house. Such, too, is the infirmity of human nature, that we really find it difficult to preserve a sufficiently romantic respect for the heroine, pretty and amiable as she is, when the saucepan is seldom out of her hand.

> " Nec tantum veneris quantum studiosa culinæ."

The finish is put to the whole by the accident which mars even the personal attractions of the heroine; for though the public were willing to regard Clarissa, after the outrage to her honour, with undiminished sympathy, it is certain they have not been equally indulgent to Amelia, after the misfortune of the broken nose.

We have already, however, in our biographical notice of Fielding, quoted so amply from Sir Walter Scott's critique upon his genius and works, that instead of pursuing an exhausted theme, we refer our readers to that article.

Smollett.

The name of Fielding always suggests that of his rival Smollett (1721–1724,) though, as writers of fiction, they rather admit of being contrasted than compared. They have, in fact, very few, if any, points in common; agreeing only perhaps in a preference for the delineation of the comic, or the common, over the impassioned and poetical. They chose different departments in novel writing, and they cultivated them by different means. As Fielding was the faithful and graphic painter of all the common features of character, so the extraordinary and the eccentric were the peculiar appanage of Smollett. He either did not feel sufficiently the charm of the natural in character, and its power of endless recombination in the hands of a great artist, or he doubted his own powers, at least in comparison with Fielding, of extracting novelty from such simple materials. But the sphere of humorous exaggeration appeared to be open to him, without the awe of a predecessor, or the dread of a rival; on that, therefore, he concentrated his powers of mind, neglecting in a great measure the other requisites of fiction; and undoubtedly with a success, which leaves him, within the province which he was the first to occupy, and with the occupation of which he was content, still the undisputed sovereign. No one has ever yet equalled him in the observation, or where that does not serve his purpose, the creation of oddities and exceptional characters which never did or could exist, but still with just enough of humanity about them, to give us an interest in their eccentric movements, or in the invention of combinations of burlesque incidents not always of the best odour, which his fertile fancy showers forth spontaneously as from a cornucopia; mistakes, rencounters, equivoques, whimsicalities of speech or action, all generally the best calculated to bring out in high raised and ludicrous relief the comic aberrations of the character represented, and to develope its latent madness; and never failing, at all events, to produce that result which Smollett seemed far more studious to attain than that of "purging the passions by pity or terror;" namely, the excitement of a broad-grin mirth, and " laughter holding both his sides." That the characters, where they have any decided features at all, are generally caricatures; for instance, that such commodores and lieutenants as Trunnion and Hatchway, never floated even under the primitive flag of Benbow; that the absurdities of Pallet are painted an inch thick; that by no human possibility could such an accumulation of comic disasters have befallen the characters of the tale, may, and indeed must be granted, even by Smollett's warmest admirers. But if, following Smollett's own example, we throw nature mainly out of the question, and look to what seems to have been his real aim, the objection of want of verisimilitude, while it may retain its truth, seems to lose half its force, and, we may add, wholly its power of conviction. It is in vain to point out the extravagance of the scene where Jolter, in an agony of terror, on hearing the direction given to put on the dead lights in the storm off Calais, goes through the steps of a mathematical proposition with infinite fervour, instead of a prayer; or to criticise the manœuvres of Trunnion, tacking his way to church on his wedding day in consequence of a head wind;—when the reader cannot see the force of the objection, through tears of laughter. In that consummation which he chiefly aimed at, and in which he rarely fails, Smollett has gained his end;—*solvuntur risu tabulæ;* the sense of the improbability of the conceptions is lost in the irrepressible merriment which they occasion.

Humour, then, was the quality in which Smollett felt himself strongest; character, incident, the excitement of the feelings, were obviously with him minor considerations. There is no difficulty in discriminating his style of humour from that of Fielding. Fielding's is calmer, chaster, perhaps of a higher kind than Smollett's, but it certainly has not its breadth, force, and felicity. As Smollett could hardly have created in its main features so gentle a humourist as Parson Adams, so he probably could have scarcely imagined a stroke of humour so delicate and appropriate to the character, as when the Parson offers to walk ten miles to fetch his sermon against Vanity, in order to convince his auditor of his total freedom from that vice. But neither, on the other hand, could he have imagined the feast after the manner of the ancients, the apparition of Pipes to the Commodore, the terrors of Pallet on learning the supposed conditions of his emancipation from the Bastille, or the ludicrous concatenation of mischances which beset the luckless inmates of the Inn in Flanders "doing or suffering." Some scenes of this sort, in which Fielding enters into competition with Smollett, such as those at the Inn at Upton, are among the least successful in his novels. The effort to raise the waters, the malice prepense in the preparation of the comic machinery, is too obvious; and after all, though he creates abundance of confusion, he raises but few smiles.

In another quality, though he has but rarely availed himself of his powers in this respect, Smollett far surpassed Fielding; we mean in his power of exciting the emotions of terror, or the sublime. From scenes of this kind, Fielding, knowing the prosaic turn of his own mind, and the limits of his invention, kept at a respectful distance; Smollett, who felt within himself the spirit of a poet, has occasionally ventured upon them, and with complete success. The robber scene in the old woman's hut in *Count Fathom*, though often imitated since, still remains one of the most impressive and agitating night pieces of its kind; and the sublimity of the situation on ship board, where Random sits chained to the poop during an engagement, covered with the blood and brains of the wounded, and screaming in delirium, has been often pointed out.

The morality of Smollett and Fielding is nearly on a par; with this difference, that the slight dash of generosity which is infused into the blackguardism of Tom Jones, while it renders him more natural, makes him at the same time more dangerous than the selfish and often ruffianly heroes of Smollett; whom we despise or dislike, even while laughing at the cruel frolics in which they indulge. The heroes of the latter are mere animals, good-natured or savage, as the fit strikes them; the heroines, with the exception perhaps of Aurelia Darnel in *Sir Lancelot Greaves*, the weakest of Smollet's works, have been justly described as objects rather of appetite than affection. In regard, indeed, to any thing like purity of morals, or gentlemanly feeling, the inferiority both of Smollett and Fielding to Richardson is obvious. Richardson sometimes mistook his means, but his aim was certainly always moral. On the contrary, both the theory and the practice of the justice were latitudinarian; and Smollett, though in real life a man of pure morals, had a boundless toleration in fiction for certain vices; for most, indeed, which did not imply want of spirit, courage, or pecuniary generosity.

In the unity of conception and coherence of incident which the plot of the novel, though more pliable than that of the drama demands, Fielding, in his two principal works (for *Joseph Andrews* was merely a parody on Richardson's *Pamela*) has a great advantage over Smollett, whose plots indeed in general scarcely deserve the name, being simply a series of strange accidents, odd rencontres, tricks and frolics, making little or no progress towards the only catastrophe which Smollett seems to have in view, namely, the marriage of his hero. In his *Roderick Random*, *Peregrine Pickle*, and *Count Fathom*, Smollett adopted the easy inartificial plan of *Gil Blas*, in which we are carried through a succession of scenes where the personages are constantly changing, and those who take part in the close of the story, are quite different from those by whom we are surrounded at its commencement. Fielding, on the contrary, both in his *Tom Jones* and *Amelia*, is singularly attentive to regularity of plan, and to the dexterous evolution and winding up of his plot, which he regarded as of vital importance. From the very commencement we perceive that he keeps his conclusion clearly in view, "and sees as from a tower the end of all." From this attention to symmetry, and tendency of all the incidents towards the catastrophe, his best work has been not inaptly ermed a prose epic; it is at all events a happy accommodaion of the principles of the epic, so far as they could be endered applicable, to the manner of the novel. One exeption ought perhaps to be made from this remark on the imperfection of Smollett's plots, in favour of that of *Humphrey Clinker*, in which the plot, though not of much art, is naturally evolved, and a quiet little family romance is gracefully combined with the usual gallery of oddities which Smollett never fails to lay before us. In all respects, this is the most pleasing of his performances. While Lesmahago may rank with the very best of his extravagances, there is more of character and less of caricature in the testy, yet kind-hearted, Matthew Bramble "frosty but kindly," than in any personage he has painted; and though the humour, as usual, is dashed with filth, without a *soupçon* of which indeed Smollett seems always to have thought it wanted pungency, the tale is entirely free from that indecency which deforms both *Roderick Random* and *Peregrine Pickle*. We rather think, too, that Smollett had the merit of originating in this novel that species of the humourous which arises from bad spelling, and which Sheridan afterwards applied to mistakes of words in his Mrs. Malaprop; a humble kind of humour no doubt in itself, yet capable, as Smollett has proved, of powerfully aiding the ludicrous effect.

Sterne.

Equal genius, though far more deformed by affectation, is visible in Sterne, (1713–1768) the first two volumes of whose *Tristram Shandy* appeared in 1759. If a regular progress of incidents towards a catastrophe, were an essential requisite in a novel, it would be difficult to bring the works of Sterne within the protection of that definition. Story he has none to tell; at all events he tells it not. But, "what is a plot good for," says Bayes, "except to bring in good things," and Sterne adopted the theory of the dramatist in its full license. At the conclusion of the eighth volume, Tristram is not emancipated from the nursery, and had Sterne lived to fulfil his threat of carrying on his work, by the aid of a vegetable diet, through as many more, the Tristrapædia, we fear, would still have made no material progress. Sterne's singular work owes its interest, as every one knows, not to the narrative, which is broken and interrupted by cross currents of the most wayward and whimsical description, far exceeding all the fair license of digression, but to his power of seizing on and bringing forward into distinct consciousness, as Coleridge says, some of those points on which every man is a humorist, and to the masterly manner in which he has brought out the characteristics of two beings of the most opposite natures, the elder Shandy and Toby, and surrounded them with a group of followers sketched with equal life and individuality: in the Corporal, the obstetric Doctor Slop; Yorick, the lively and careless parson; the widow Wadman, and Susannah.

The clue which Sterne chiefly follows through the mazes of character, is humour;—humour of a very high and peculiar kind, perfectly original, at least in English. For that species of riotous humour arising from comic peculiarities of person, and combinations of ludicrous mischances, Sterne has little taste; though the admirably painted scene, where Obadiah on the cart horse, careering round the corner like a comet, oversets Dr. Slop in a whirlpool of mud;—and the cross bills filed by the Doctor and Susannah against each other in applying the cataplasm, show, that if he had considered this the highest walk of humour, he might have revelled in it as easily as Smollett himself. But, like Fielding, he preferred the humour which arises from bringing out by light and happy touches, and as if unconsciously, the secrets of character; only with this difference in his favour, that with Sterne the humour is steeped in sensibility. Flowing, as it does, as much from the heart as the head, it speaks also to the affections; calm smiles ripple over the countenance as we read, but tears are in the next degree. Thus, in Sterne, humour and feeling heighten and set off each other; the pathetic rises in gentle relief out of the background of the comic, and sinks gracefully and imperceptibly back into it again. It is this, for instance, which gives so irresistible a charm to the story of Le Fevre, and the Corporal's account in the kitchen of the death of Tristram's elder brother, enforced by the eloquent stroke of dropping the hat, as if a lump of clay had been kneaded into the crown of it. There is nothing sneering, nothing unkindly, nothing that revolts the better feelings in his playful irony. *Circum præcordia ludit.* That of Swift and Voltaire is blighting like an east wind; the sympathies of the heart close themselves up against it; but beneath the genial and balmy humour of Cervantes and Sterne, they relax and blow like flowers expanding beneath the west wind in spring.

The wonderful resources of characteristic invention, and the very finest perception of the limits of true humour, are shown in the contrasted characters of the two brothers, the main personages in the history; the man of pure intellect, restless, nervous, eloquent, hair-splitting, half-crazed by learned theories, which he insists on carrying into action, craving sympathy, and yet courting discussion, as delineated in the elder Shandy; and the man of pure good nature and benevolence, as drawn in Toby; without learning, with no head for reasoning, but with a heart always in the right place; eloquent too, in his way, when his feelings are touched, or his favourite pursuits depreciated, (witness his animated and beautiful defence of his reasons for prolonging the war) chaste as a woman, gentle, harmless and credulous as a child; riding his hobby, in short, in so captivating a manner, that, if the truth were told, most of his readers are in their hearts inclined to mount along with him. There are few, we suppose, who have not been seduced into something of his own mania by the scene on the bowling green, when he discovers the ingenious invention by which Trim, having converted the jackboots into mortars, is directing a hot fire from these engines against the counterscarp of Lisle; when the tobacco pipes, withdrawn from the mouth of the corporal, are gradually insinuated into his own, merely to try them; and puff succeeds puff, till the enthusiast is swept into the torrent of a furious cannonade. Nothing, too, can be at once more humourous or characteristic than that scene where Toby mistakes the elder Shandy's quotation from Sulpicius' consolatory letter to Cicero, for a real account of his brother's trip to the Levant, a stroke of humour so natural in the circumstances, and yet so original, that it would of itself be sufficient to prove that Sterne was a man of genius.

The two great defects of Sterne, as noticed by Sir Walter Scott, are his affectation and his indefensible indecency. For his plagiarisms from other authors, we regard as of little importance. So ingeniously are they turned to account, and so much in general does Sterne improve what he borrows, that he may fairly claim in them that right of property which the civil law allowed in articles where the labour bestowed by the borrower exceeded the intrinsic value of the material on which it was bestowed. It must be confessed, however, that few writers have carried their coolness and assurance in this respect so far as Sterne has done, who, not content with denouncing the plagiarisms of authors, has actually stolen from Burton the passage in which he exposes the iniquities of his neighbours.

But the other objections less admit of defence. The affectation of Sterne is the more to be regretted, because his manner in its happiest moods is the very perfection of a lively, spirited, spoken style, idiomatic, imaginative, pliant, and varied. "Writing, when properly managed," he himself observes, "is but a different name for conversation." Unfortunately he did not always conform his practice to his precept. He is sometimes *fade* in his sentimentality, and aiming after a sort of false sublime in his imagery. Some portions of the story of Maria are examples of the first; the well-known personification of the recording angel in the close of Le Fevre, is an instance of the second. Still more unworthy of Sterne are those quackeries of the black page and the white one, the sudden transitions and affected openings of the chapters, with other harlequinades of authorship, which are carried to excess in *Tristram Shandy*.

The indecency of Sterne is more obtrusive and indefensible than that of either Fielding or Smollett; whose highly-coloured scenes seem to be the result of an unchecked imagination, running on heedless whether its course lie through purity or filth. Sterne, on the other hand, goes coldly and deliberately in search of impurity; seeks for it in books, refines upon it, mixes it up with his reflections, and is continually insinuating some equivoque or double entendre into scenes where we can ill bear with such adulteration.

Richardson, Fielding, Smollett, and Sterne, are the four great novelists of this period (the reign of George II.) which was pre-eminently the age of novel-writing in England. For though we should indeed be sorry to undervalue the merits of Goldsmith, or the charm of his *Vicar of Wakefield*, we cannot quite rank the powers displayed in that delightful little tale, which appeared in 1763, so highly as the varied invention displayed by the writers we have named, upon the broader canvass which they selected. To use his own words, it has many faults, and a hundred things might plausibly be said to prove them beauties. Fortunately, they lie more in the minor parts, than in the essentials of the tale. In fact, the improbability of the plot is only equalled by the wonderful truth, nature and keeping of the principal character, for the "limæ labor" which, in this instance, Goldsmith willingly bestowed upon his style, and on the creation and apposition of traits of character, he scrupled to waste upon the selection of his incidents. The real interest lies in the development in the character of the amiable Vicar, so rich in heavenly, so poor in earthly wisdom;—possessing little for himself, yet ready to make that little less, whenever misery appeals to his compassion;—with enough of literary vanity about him to shew that he shares the weaknesses of our nature,—ready to be imposed upon by cosmogonies and fictitious bills of exchange, and yet commanding, by the simple and serene dignity of goodness, the respect even of the profligate, and making "those who came to mock remain to pray." Doubtless, the probability and look of life which a character drawn with such quiet strokes of the pencil, and with such sobriety of colouring, possesses, is in some measure owing to the fact, that not a few of the incidents of which Goldsmith has availed himself, are drawn from circumstances in his personal history, such as the mistake of setting out to teach the French English, without recollecting that it was a necessary preliminary for the tutor to acquire a little French himself; but the skill which can make such trifles in real life subservient to the purposes of real fiction, is scarcely less worthy of praise than would have been their original invention. Perhaps there is no better proof of the broad and general truth of delineation which a novel possesses, than our being in the habit of resorting to it in conversation for cases in point, and comic illustrations of our opinions. In this respect the *Vicar of Wakefield* forms a storehouse of allusion. How naturally does any ridiculous investment in Mexican mines, or Spanish stock, recall to our recollection Moses' bargain for the gross of green spectacles? Who is there that has not been reminded of the aristocratic Miss Skeggs turning out to be no better than she should be, notwithstanding her intimacy with the Duchess, and her taste for Shakspeare and the musical glasses, by some case of the same kind within our own experience, where, reversing the denouement of the Double Arrangement, the Knight Templar of the company has sunk into the waiter? And for our own part, we must admit, that we have never been able to treat with due gravity any allusion to the learned speculations of Manetho, Berosus, or Sanconiathon, from their indissoluble connexion in our minds with the more finished cosmogony of Jenkinson.

In one respect Goldsmith rises conspicuously superior to his brethren; he has no passages, which, dying, he need have wished to blot, and his characters and his incidents are all calculated to call forth only the better feelings of our nature. *Virginibus puerisque* might have been his appropriate and uncontested motto.

The great novelists to whom we have alluded, and particularly Fielding, Smollett, and Sterne, had of course many imitators. But the minuteness of Richardson was found to be intolerable in any hands but his own, and his manner in this country at least, though not in France and Germany, was soon abandoned. Amongst the numerous imitations of Fielding's manner, most of which are now forgotten, the *Henry* of Cumberland (1752–1811), is probably the most respectable. Cumberland possessed that degree of talent which enabled him, both in dramatic composition, and in the novel, to produce performances which are read with pleasure, though they seldom rouse our interest, and never impress us with the idea of a creative genius. Accordingly, both his *Arundel* and his *Henry* have enjoyed a fair measure of popularity, particularly the latter, in which a story of tolerable interest is made the vehicle of displaying considerable acquaintance with English life in the lower ranks, derived from Cumberland's familiarity with such scenes in his early residence in Kent,—while the homeliness of these pictures is relieved by many rural landscapes perfectly English. The tale has the fault of *Pamela*, that aims at teaching virtue through scenes that border very closely on vice; while, as Sir Walter Scott remarks, Cumberland reverses the usual process of courtship, and "throws upon the softer sex the task of wooing, which is more gracefully as well as naturally the province of the man." The characters have little novelty; Cumberland was indebted for them to *Joseph Andrews*, and he took the idea of his plan and style from *Tom Jones*. Henry is another version of Joseph himself, which Cumberland somehow seems not to have perceived to be a caricature created in the mere spirit of parody; but the portrait of an amiable, enthusiastic, and yet absurd Methodist parson in *Ezekiel Daw*, has an air of originality, even when placed beside that of Parson Adams, by which it was obviously suggested.

The imitations of Smollett's manner were not numerous, and, with one exception, totally without merit. We allude to *The Adventures of a Guinea*, by Charles Johnstone, which appeared in 1761, in which a series of scenes and personages in different walks of life are brought before us through the somewhat inartificial method of making a coin, which shifts through the hands of successive proprietors, the historian of their follies and their vices; a contrivance very inferior indeed to the ingenious machinery by which Asmodeus unveils to Don Cleofas the secrets of Spanish life. In *The Adventures of a Guinea*, the author seems to have had before him both Le Sage and Smollett as models; but in the result he exhibits little of the gay good-humoured touch of the Frenchman, and nothing of the cordial merriment of the Scotchman. Where Le Sage painted follies, and Smollett frolics and absurdities, Johnstone, on whom some have conferred the high title of a prose Juvenal, delineated with a sarcastic and energetic brevity, the darkest vices and crimes of an age in which both political and domestic profligacy prevailed, and were paraded abroad with no ordinary degree of assurance. "In Johnstone's time," says Sir Walter Scott, "the reform which was introduced by the private virtues and patriotism of George III. had not commenced; and he might well have said, with such an ardent temper as he seems to have possessed, 'Difficile est satyram non scribere.' He has accordingly indulged his wit to the utmost, and as most of his characters were living persons, then easily recognised, he held the mirror to nature even when it reflects such horrible features. His language is firm and energetic; his power of personifying character striking and forcible, and the personages of his narrative move, breathe, and speak in all the freshness of life." This is high, and indeed we think, with deference, exaggerated praise. Who remembers or can name a single character which Johnstone has drawn, except perhaps his forcible but odious caricature of Whitefield? What scene of real interest or passion has he painted in such a manner as to give it a home in our memories, like the better scenes of Fielding or Le Sage? Not one: and indeed, bad as the age which he painted was, we believe he has greatly exaggerated its vices, or at least his one-sided views have led him to keep out of sight its redeeming points and countervailing virtues. Hence the impression the book leaves on the mind is one of oppression. It leads us along all the gloomy, and foul, and noisome passages of life, and we escape from it with the feeling of relief with which we would emerge from a vault in which the air was loaded with noxious vapour.

Mackenzie.

Sterne is perhaps the only one of our great novelists who has found an imitator of genius, in Mackenzie (1745–1831); for although in his *Man of the World*, and *Julia de Roubigne*, Mackenzie has deviated from the manner of Sterne, and formed a composite manner, in which the characteristics of several writers are blended with his own, yet there can be little doubt that the spirit of Sterne, in his pathetic passages, in a great measure inspired *The Man of Feeling*, and prompted that "illustration of the richer and finer sensibilities of the human breast," which Sir Walter Scott points out as the "key-note" on which he formed his tales of fictitious woe. In some obvious respects, no doubt, Mackenzie improved upon his model; as in rejecting the licentiousness of Sterne's wit, retrenching his episodical digressions, his numerous impertinencies, and intrusive buffoonery, and keeping the strain of feeling which he wishes to create more unbroken; but as writers of genius, there surely can be no comparison between them. Mackenzie has none of those charming touches which hover with such a fine ambiguity between the pathetic and the humorous,—like Toby's opening the window, and liberating the fly which had been buzzing about him all day,—and which operate, like spells, upon the heart. We fear, then, that the spirit of nationality, and the bias of private friendship, has led Sir Walter Scott somewhat to exaggerate the claims of Mackenzie, who, if he has less affectation in mere manner and style, seems to us to have more affectation of feeling than the author of *Tristram Shandy*. In fact, Mackenzie betrays in some passages of his novels a tendency towards that unhealthy sentimentalism which was afterwards carried to such a sickly excess by inferior imitators of Sterne. Such is certainly the case in what is commonly considered the most powerful, though, we think, the least pleasing of his works, *Julia de Roubigne*. No doubt, if the chief aim of fiction were "to send the hearers weeping to their beds," Mackenzie might claim the merit of having attained it. But though the distresses of the story may be in themselves naturally pourtrayed, the constant monotony of melancholy which it presents to us is not so; it is morbid and out of nature, and the feeling with which it is perused, which is that of exhaustion and uneasiness, shews that the writer has missed the great aim of fiction, which is to make even suffering minister to a soothing feeling of sympathy, and to leave upon the mind at the close a sentiment of consolation.

The Man of the World is exposed in some respects to the same objection. The suffering, the accumulation of misfortunes which are heaped upon the innocent Anneslеys, through the heartless villainy of Sindall, are too unmitigated. The story wants repose, relief, and sunshine. It is like an avenue of cypresses terminating in a tomb. *The Man of Feeling*, the first of Mackenzie's productions, is, after all, the best. It is more unlaboured than the others, has more of the first freshness of the author's mind about it; and its brief manner, and quicker succession of situations,—for they can hardly be called incidents, relieve it from that sombre uniformity which, in his larger novels, produces such a depressing effect.

Dr. Johnson.

The *Rasselas* of Dr. Johnson (1709–1783), though it wears the form of a tale, has but slender pretensions to be included amongst the class of novels, for it has neither progressive incident nor character. It is a series of dialogues and moral reflections, very solemnly and beautifully written, tinged with that tone of mournfulness and despondency so likely to be the prevailing feeling of his mind in the composition of a work intended to defray the expenses of a mother's funeral. *Rasselas* is, in fact, the *Vanity of human wishes* in prose; and its incidents, if such they may be called, have even less pretensions to connected interest than those of *Candide*, to which it may be regarded as a moral and philosophical antithesis.

Judging, indeed, from *Rasselas*, and from the other writings of Johnson, it may be safely assumed, that his success as a novelist would not have been much greater than as a dramatic poet. He has nowhere shewn the least power of creation, by stepping out of himself, and putting on by the force of imagination the nature of others. Through the disguise of all the successive characters which he is obliged to assume in the *Rambler*, the sturdy, controversial, and somewhat pompous moralist stands confessed; and whether he writes as a fine lady, a fop, a blood, or an elderly gentleman, still, like Puck, "we know the man by the Athenian garments he hath on." Independently of this, his views of life would certainly have been untrue, inasmuch as they were one-sided. Far from being disposed "to make the happiness he could not find," the tendency of his mind,—in consequence, perhaps, of a constitutional melancholy,—was rather to unmake and neutralise the elements of comfort by which human life, in the average, is surrounded. Had he devoted himself in earnest to fictitious composition, he would have lent his eloquence and power of forcible statement, to shape the world of romance according to the gloomy fashion which the reality presented to his eye; and in an inky coat, indeed, or a drab-coloured suit at best, very unlike the peach-blossom of his friend Goldsmith, he would in all probability have arrayed it.

Horace Walpole.

About 1769, we witness the revival, though in a new shape, of the old taste for Romance. The delineation of life as it actually existed, was found to afford too little scope to minds who aspired after the imaginative and poetical, and who could not see why natural delineation of character and manners might not be combined with striking events, and with the picture of the higher passions; why, as Walpole expresses it, in his preface to the *Castle of Otranto*, "the fancy might not be left to expatiate through the boundless realms of invention, and thence to create more interesting situations, while the mortal agents in the drama still conducted themselves according to the rules of probability." In the first shape, however, in which romance reappeared, after this temporary slumber, the delineation of character occupied, it must be owned, but a very subordinate place. A little more attention was given to verisimilitude of manners, and much was done to abbreviate the tedious style of the old prose romance, and to throw life and movement into the narrative by dialogue, and by the omission of unimportant incidents not bearing on the catastrophe; but the main efforts of our first modern romance writers were directed chiefly to the excitement of that feeling of love of the marvellous which exists more or less in every human breast. They chose for their favourite themes the varieties of the supernatural.

> "Somnia, terrores magicos, miracula, sagas,
> Nocturnos lemures portentaque."

We admit that the author of the *Castle of Otranto* did not trust exclusively to such materials of interest. But granting that the general outlines of "his feudal tyrant, his distressed damsels, his resigned yet dignified churchman," are sufficiently correct, we are at a loss to perceive in any of his characters that individuality which gives to such pictures their chief value. To us they seem light, sketchy, and somewhat vague, although we think it quite possible that the effect produced by greater truth and distinctness of feature in the mortal agents of the piece, might not have harmonised with the extravagant demands upon the imagination which the author makes by his supernatural machinery. We agree with Sir Walter Scott, in thinking Walpole acted with judgment in leaving his machinery without those attempts at explanation introduced by Mrs. Radcliffe, always inadequate, and even throwing an air of ridicule over the mysteries of the piece upon a second perusal. But we cannot concur with him in his toleration of the extent to which Walpole has carried the marvels and improbabilities of his romance. The apparition of Alfonso in the moonlight, dilated to a gigantic form, is impressive, and in certain moods of the mind even the skeleton ghost in the hermit's cowl may have its terrors. But Clara Reeve was certainly right in the protest which she enters in her preface against the introduction of such machinery as that of a sword so large as to require a hundred men to lift it; a helmet that, by its own weight, forces a passage through a court yard into an arched vault, and crushes a boy to death; or a picture walking out of its frame. The effect of such violent instruments of terror is suicidal; they destroy the very feeling they were intended to create, and give to the romance the air of a nursery tale. Indeed, were it not for the singular charm of the style, which, like all Walpole's compositions, is of the purest and most idiomatic English, and terse and condensed in a very high degree, we feel persuaded that the *Castle of Otranto*, although the first specimen of the modern romance, would at the present day find few admirers.

Clara Reeve.

In some respects, then, we think the *Old English Baron* of Clara Reeve was an improvement on the *Castle of Otranto*. For there the marvellous was brought within some limit of proportion; "the extravagant and erring spirit hied to his confine," and, consequently, so far as regarded the creation of an impression of superstitious terror, or giving an air of probability and keeping to her narrative, we must admit, that her ghost of Lord Lovel, who is always exhibited under the obscurity of a dim religious light, did, in our youthful days, produce upon us a certain species of awe. In other respects, we rather fear the apprehension which is expressed in her preface, namely, that in avoiding the defects of Walpole, the spirit of his wild composition might evaporate, was not altogether without foundation. The style of the narrative in her hands became heavy, often dry and vulgar, like the ancient chronicle she professes to follow; her dialogue is peculiarly flat and cumbrous, and the plot deformed, and rendered tedious by trifling incidents which now appear to us needlessly homely; and yet the strong interest with which, as we can state from experience, this romance is perused at an early age, is a proof that in the cardinal point of exciting curiosity, and a feeling of mysterious interest, the ruder narrative of Clara Reeve effects, in a great measure, what all the liveliness of style, the deeper antiquarian reading, and more creative fancy of Walpole, failed to attain.

Mrs. Radcliffe.

But this species of romance writing was probably carried to its perfection by Mrs. Radcliffe (1764-1823), who, in her own walk of fiction, has never been excelled, though opinions may differ as to the comparative rank which she holds among writers of fiction, and also as to the soundness of that principle of composition which led her systematically to unravel her own spells, and to attempt an explanation by natural means, of effects which we had at first been encouraged to refer to the agency of supernatural causes. Indeed, we might rather say, that, in regard to this last point, there is no room for doubt, and that this system of explanations is exposed to every possible objection;—as totally inadequate in general, to account for the effects ascribed to it; as running counter to the whole tone of sentiment created up to the period of explanation,—as disappointing the pride of the reader, who feels offended at the thought that he has expended so much anxiety and terror on a mere "painted devil," and a succession of mockeries; and is consequently annoyed at this common-place anticlimax, after his nerves have been tuned for grand wonders, instead of the discovery of paltry images of wax-work. Indeed, it is one of the strongest proofs of the redeeming genius which Mrs. Radcliffe has thrown into her tales, constructed, as they are, upon so unsatisfactory a plan, that they bear a second perusal at all; or that having discovered in one or two cases the inadequate and puerile nature of what appeared at first so appalling and formidable, we still feel eager for the solution of the remaining mysteries, and can hardly persuade ourselves but that something strange and fearful does lurk, after all, within her deserted chambers, and beneath her faded tapestry.

It is the more to be regretted that Mrs. Radcliffe adopted this principle, because all the excellencies of her peculiar genius might have been displayed with equal effect, if she had chosen a more satisfactory plan of composition. Why she should have hesitated to admit of an actual spiritual agency, it is difficult to discover. Fear, when its object is something corporeal, is no doubt the basest and vulgarest of feelings. But when its source lies in the invisible, and when we shrink at the thoughts of the visionary and the eternal, it puts on the character of sublimity. Standing, as we do, on the confines of a dim eternity, which we believe but cannot see, the feeling which prompts us to a communion with the world of spirits, and yet makes us shrink and tremble at our own daring, exists to such an extent in all minds, and not the least in the most heroic, as to afford a basis on which high imagination may always operate with effect, so as to justify the artful use of the supernatural. We say the *artful* use, for every thing depends on the skill with which such machinery is used, the address of the preparation, and the judgment with which the accessories and the background are selected. Who feels the slightest symptom of awe when the shade of Amphiaraus appears before the assembled people to forbid the banns between Eriphyle and Alcmæon, or that of Ninus emerges in broad day from the tomb, in Voltaire's *Semiramis?* Who does not,—at least in reading the play,—experience a pleasing thrill of fear, when, in the depth of a December night, with the sea moaning behind, and the bell then beating one, the majesty of buried Denmark advances with spectral stalk along the platform of Elsineur? We grant there has been few successful attempts in modern times to keep up the interest of a story turning upon machinery avowedly supernatural, but we are far from thinking that such an attempt might not, even yet, in our days of illumination, be made by a man of genius, so as to move the pulses of terror with complete success.

But besides the actual field of the supernatural, there are many equivocal phenomena in our nature, lying within that debateable land where mind and body meet, such as dreams, omens, and presentiments, which admit of being referred by he mind, in an excited state, to supernatural causes, and which may be employed with powerful effect by writers of fiction, without the possession of that creative genius and knowledge of the human heart which are required to present the sheeted dead in a shape and garb of terror calcuated to impress and awe the imagination. And such, in fact, is the diluted shape in which the supernatural is generally presented by our modern romance writers.

From all these sources of emotion, Mrs. Radcliffe has unfortunately excluded herself by her system of sufficient reason founded on natural causes. And yet it is wonderful what a magical power she exercises within the field to which she restricts herself. No one ever seems to have nderstood better the art of preparation, the attunement of the mind to the key of the supernatural, by a long train of half-heard sounds, and glimpses of sights, which the fancy, amidst night and silence, works up for itself into images of things which it fears to contemplate.

> Like one that on a lonesome road
> Doth walk in fear and dread;
> And having once looked round, walks on,
> And turns no more his head,—
> Because he knows a frightful fiend
> Doth close behind him tread.

And perhaps the strongest proof of her judgment is to be found in the economy and reserve with which she employs the talisman of terror. In her hands slight circumstances and half hints are made to produce all the effect of fearful witcheries or scenes of bloodshed and horror. The clang of a distant door, a footfall or a track of blood upon a staircase, a strain of music floating over a forest, a figure pacing a platform in silence, some wandering voice following us, "with airy tongue that syllables men's names," through the passages of a decaying chateau, the heaving of the tapestry of a bed in some deserted chamber, nay, at last a very rat behind the arras, become invested with a mysterious dignity, and work upon the imagination like spells. The disappearance of Ludovico, for instance, in the haunted apartment of Chateau Le Blanc, where he had undertaken to watch, prepared as it is by a train of little details which act upon the nerves, and by the masterly ghost story of *Bevys of Lancaster*, which he is represented as perusing, may be safely pointed out as a *coup de maitre* in the art of raising to its highest pitch, the feeling of curiosity and suspense.

Whether Mrs. Radcliffe possessed much power of painting character seems doubtful; it is at least certain she has shown but little. In such calculations of probability, we can only use Sebastian's words.—"What *had been* is unknown, what *is*, appears." She seems indeed to have borrowed a hint from Bayes, which like many other remarks of that worthy, have more good sense in them than was perhaps apparent to the noble parodist, and purposely to have "underwrit some parts in order to set off the rest:" in other words, she has systematically kept the delineation of her characters subordinate to her main object, the maintenance of a mysterious curiosity, which never *is*, but always *is to be* gratified. Her tales, indeed, would have probably gained little by greater discrimination in this respect, if in truth the species of interest produced by the natural would not have rather interfered with that arising from the marvellous. For her object, it was sufficient that as the representatives of classes, rather than individuals, her personages should be sketched spiritedly but lightly; that the straight-laced heroine in white satin, should be duly supported by the gossiping waiting woman in white muslin, and that the bandit chief of the Appenines, the hired robber, the scowling monk, or the chattering peasant should wear with a natural air the outward and conventional badges of their calling. The nearest approach she has made to character, is in her Schidoni, whose outward appearance is most picturesquely and impressingly described, while the inscrutable mystery which at first hangs over the inward man, the dark hints which are dropped concerning him by others, and the gradual revelation of his designs in his conversations with the Marchioness, powerfully stimulate our interest, and make us follow all his actions with an instinctive feeling of alarm. The misfortune is that even in this, the most finished of her portraits, the Schidoni of the second is really not the Schidoni of the first portion of the tale. When "the father softens," the confessor unfortunately can no longer "remain fixed;" when he ceases to be the mere evil spirit of the romance, puts on the look even of a guilty humanity, and turns out to be simply "a bold bad man," he loses his identity, and with that his influence over the imagination.

Mrs. Radcliffe may claim the merit of being the first to introduce landscape painting into her romances as a component part of the interest of the piece. The frequency of her pictures of external scenery, and their want of distinctness and local truth, have indeed been blamed by many who would willingly, on Puff's principle, have abridged her descriptions of the rising sun, and dispensed with a great deal about gilding the eastern hemisphere. But it is certain that these descriptions, though occasionally tedious, and sometimes too obviously brought forward upon a principle of melo-dramatic contrast, have a powerful effect in heightening the impression communicated by the incidents or the sentiments. Set off against the calm beauty of a summer evening, or the magnificent gloom of a thunder storm, her pastoral or banditti groupes stand out with double effect; while to the charge of vagueness of description, it may be answered, that Mrs. Radcliffe is by no means vague, where distinctness of imagery is, or ought to be her object; as any one may satisfy himself who recalls to his recollection her description of the lonely house by the Mediterranean, with the scudding clouds, the screaming sea-birds, and the stormy sea, the scene selected for the murder of Ellena;—or another picture, in the best manner of Salvator, of the first glimpse of the Castle of Udolpho rising over a mountain pass, with the slant sunbeam lighting up its ancient weather-beaten towers. Indeed, the whole description of that Appenine fastness, both without and within, is in the best style, not of literal indeed, but of imaginative painting—"fate sits on those dark battlements and frowns:" the very intricacy of its internal architecture, and its endless passages,—a mighty maze, and we fear without a plan,—only serve to deepen the impression of imprisonment and bewilderment and gloom.

Less, certainly, is to be said for those descriptions in verse with which her novels are rather profusely interspersed, and which are, of course, represented as emanating from some of the personages of her stories. Without denying the merit of some of her occasional verses, it is certain that she always shews more of the spirit of poetry in her prose. Indeed, independently of the mediocrity of many of these effusions, they often assume a ludicrous air from their contrast with the circumstances under which they are produced. Under all situations of alarm and anxiety, in the seclusion of convents, and in the castles of Condottieri, where drunken ruffians are brawling "along the corridor," paper, pencils, and poetical enthusiasm are never wanting to her heroines, and the sun is seldom suffered to rise or set without a tribute to his beams. Indeed, it is even observable that the poetical sensibilities of her heroines generally become more lively after any domestic calamity, such as the demise of a parent; as Beau Clincher's exuberance of spirits was accounted for by the fact, that he was in mourning for his father.

For a particular notice of the individual works of Mrs. Radcliffe, we refer to our biographical article on that subject. Two of them are now wholly and deservedly forgotten. Neither the *Castles of Athlin and Dunbayne*, nor the *Sicilian Romance*, crowded with violent yet ineffective incidents, gave any indication of that ability which she afterwards displayed. Of her remaining fictions, it may be said in a word, that the *Romance of the Forest*, founded on a French *cause celebre*, has the fewest faults; that the *Italian*, though extremely unequal, and in the third volume a comparative failure, contains the most striking and dramatic scenes; but that the *Mysteries of Udolpho* is on the whole, and justly, considered the best.

To be fully enjoyed, the Romances of Mrs. Radcliffe must be perused in youth. In after age, they appear too uniformly visionary, and the straight-laced stiffness of her heroines, who never manifest the least warmth except in poetry, "female punctuation not permitting them to do more," as Mrs. Malaprop observes, suggests the recollection of the pruderies of the pastoral and heroic romance. But when these tales are read in youth, and only remembered in manhood in their better portions, they leave upon the memory a pleasing impression of a varied pageant of gloomy castles and caves, moon-illumined streets and palaces, "dance and Provençal song and vintage mirth," aerial music floating over haunted forests, or the chant of monk or nun borne to the ear over the waters of some Italian lake, amidst the stillness and the shadows of evening.

We have devoted a larger space to Mrs. Radcliffe than some may think justly due to the rank in fiction which she occupies, but we have done so,—first, because we think justice has seldom been done to the real genius which she threw into the style of fiction she chose to adopt, whatever may be its precise order of precedence in the calendar of fiction; and, secondly, because, although that style became more universally popular, and more generally imitated than any which had preceded it, she herself, with two exceptions only, which we shall notice, remains the solitary writer of genius by whom it has been adorned. The truth is, that the sarcasms which have been directed against the puerile horrors of Mrs. Radcliffe ought justly to have been confined to the extravagances of her successors, who imitated her manner without either her imagination or her judgment, and conceived that the surest means of producing effect consisted in pressing the springs of the terrible as far as they would go. In the hands of these, "imitated imitators," the castles became twice as large and ten times as perplexing in their architecture; the heroine could not open an empty drawer without stumbling on a mysterious manuscript written by her father or mother; nor leave her room to take a twilight walk, of which heroines are always strangely fond, without stumbling on a nest of banditti; the gleam of daggers grew more incessant; the faces of the monks longer and more cadaverous, and the visits of ghosts so common-place, that they came at last to be viewed with the same indifference by the reader, as they were of old by honest Aubrey, or less honest Dr. Dee.

One word may be said in favour of the Romances of Mrs. Radcliffe and her school, addressed to those who think that every romance should embody the moral conveyed in the concluding couplet of the *Mourning Bride*. Their general tendency is moral, poetical justice is in most cases rigidly enforced, and crime punished, and virtue rewarded by some unexpected good fortune, even on this earth. "All this," says Mr. Dunlop, "may be very absurd, but life, perhaps, has few better things than sitting at the chimney corner in a winter evening, after a well-spent day, and reading such absurdities."

Lewis

The two exceptions from the general dullness and common place of the imitators of Mrs. Radcliffe, are *The Monk of M. G. Lewis*, which appeared in 1796, and *The Montorio of Maturin*, published in 1807, and among the last romances written on that now antiquated plan. Much injustice, we believe, was done to Lewis at the time. A single unfortunate remark of an irreligious tendency, and some descriptions of undue warmth, pardonable in a youth of twenty, and retrenched in the second edition, gave a blow to the popularity of this romance from which it never recovered. And yet the traces of considerable genius are visible both in its plan and in the execution of several of its powerful scenes. The mere hint of the story, that is to say, the general idea of the gradual corruption of a proud, and enthusiastic, and self-relying nature, was taken, as Lewis acknowledged, from that of the Santon Barsisa in the *Guardian;* the incident of the escape of the baroness from the banditti, was an expansion, executed with much skill, of the scene in the hut in *Count Fathom;* for the story of the bleeding nun, he was indebted to a German legend, while he has borrowed several hints for his wandering Jew from the incomprehensible Armenian of Schiller. But to these hackneyed materials he has given a force and look of novelty that are surprising; the escape, the conjuration scene, where the Jew, withdrawing the black ribband, unveils the burning cross on his forehead; the procession of St. Clare by torch-light, where the abbess is torn to pieces, once read are not easily forgotten. Lewis also avoided Mrs. Radcliffe's error; his ghosts are real, and his devil genuine, though, as is not uncommon, we believe, in practice, he takes the form of a woman, instead of appearing, as Defoe has it, "in all his formalities and frightfuls."

The *Montorio* of Maturin was also a boyish production, which the writer affected at a more advanced period of life to despise. Yet it appears to us to exhibit more genius, mingled, no doubt, with a deep vein of extravagance and false taste, than his more claborate attempts to picture real manners and passions in his *Woman.* There was originality even in the conception, hideous as it was, of the hero employing against the brother, who had deceived him, the agency of that brother's own sons, whom he persuades to parricide, by working on their visionary fears and by the doctrines of fatalism; and then, when the deed is done, discovering that the victims whom he had reasoned and persecuted into crime were his own children. And though Maturin's machinery in no respect differs from that of his brethren, though he labours to explain away in the close all that had appeared supernatural in the beginning, and of course with total want of success, yet the impression left on the mind by the perusal of the work, in the three thickest volumes we believe that modern romance has to boast of, though gloomy and unsatisfactory, is certainly that of an inventive genius in the author. Such was the effect it produced on Sir Walter Scott, who was the first to direct attention to it, by a criticism in the *Quarterly Review* for 1810. "We have strolled," says he in a lively introduction, "through a variety of castles, each of which was regularly called Il Castello; met with many captains of condottieri; heard various ejaculations of Santa Maria and Diabolo; read, by a decaying lamp, and in a tapestried chamber, dozens of legends as stupid as the main history; examined such suites of deserted apartments as might set up a reasonable barrack, and saw as many glimmering lights as would make a respectable illumination. Amidst these flat imitations of the *Castle of Udolpho*, we lighted unexpectedly upon the work which is the subject of the present article, and in defiance of the very bad taste in which it is composed, we found ourselves unusually involved in the perusal, and at times impressed with no common degree of respect for the powers of the author."

Of the Zelucco of Dr. Moore, which appeared about 1785, we have already spoken at some length in our Biographical article.

The influence of such works as Goethe's *Sorrows of Werther*, written seemingly with the view of reversing Pope's maxim, and proving that whatever is is wrong, becomes very obvious in our literature of fiction towards the close of the eighteenth century. For, in truth, such speculations, embodied in an imaginative form, were found highly congenial to that spirit of restlessness and discontent with political institutions which was every where abroad, perplexing nations with fear of change, and leading men of genius to dress up moral paradoxes in the shape of narrative, and to employ their eloquence in attacking those principles of society which tend to make men happy, or which keep them so. This tendency appears sufficiently obvious in the novels of Bage, a sceptic in religion, and a latitudinarian in morals, whose crude theories, we think, might have been allowed to repose in that oblivion to which they had been consigned, without being revived in such a work as the *Novelist's Library.* Their introduction at all into a work intended to embody only the classical works of fiction, seems unaccountable; nor is the singularity diminished by the fact that his best work, *Hermsprong, or Man as he is not*, is omitted, while three of inferior merit are re-published.

But the social and political theories of the time found an abler exponent in Godwin, whose first work, *Caleb Williams*, appeared in 1794, in which, throwing aside the stimulus of the marvellous, he has trusted the effect of his tale entirely to a picture of the workings of the mind on two beings of very opposite natures, who are driven, by a species of fatal instinct, into the relative positions of persecutor and victim. The doctrines of the *Political Justice* furnished avowedly the primary source of the inspiration of *Caleb Williams*, intended, to use the words of the preface, "to furnish a general review of the modes of domestic and unrecorded despotism, by which man becomes the destroyer of man;" that is to say, to shew that, under the maladministration of English law, liable to be perverted by influence and wealth, the chances are all in favour of the escape of the real criminal and the conviction of the innocent; a proposition notoriously untrue, and which is not even advocated with much art or plausibility in the series of persecutions to which Williams is exposed. Fortunately, however, for the real merit and permanent popularity of this singular work, the political design soon merges in a higher and more legitimate interest. The genius of the author kindles as he proceeds, and out of a hard and republican background brings forth the bright and chivalrous vision of the aristocratic Falkland, a being of a loving noble nature, the victim of false honour and morbid refinement of feeling. Few scenes in romance exceed in breathless and entrancing interest the description of the progress of suspicion in the mind of Williams, till he extorts from his master the fatal secret, on which hangs the whole of his future fate; the escape from prison in the grey dawn of a drizzling morning; and the last interview between Williams and his dying persecutor, sitting, corpse-like, to hear his secret disclosed to the world, and to suffer the agony of knowing that life and reputation are about to leave him together.

St. Leon.

In none of his other works did Godwin evince the same grandeur of conception, and in none of his subsequent personations, except Bethlehem Gabor, did he exhibit that power of presenting demoniacal characters, such as Tyrrell and Gines, in a light which renders them, unnatural as they are, actual objects of terror, like a serpent in the path. The tone of his next novel, *St. Leon*, is altogether more subdued than that of *Caleb Williams.* It has a mournful eloquence in harmony with the picture of desolation which it presents. Here, too, the author has imperfectly succeeded in working out the design which he announces he had in view; namely, that of proving that the happiness of mankind would not have been augmented by the gifts of immortal youth and inexhaustible riches; for, in order to illustrate his position, Godwin is under the necessity of laying the scene in a remote age, and making the persecutions of St. Leon arise from feelings of superstitious credulity, which we cannot help recollecting that the progress of intelligence has since exploded. The senior wrangler, who asked what *Paradise Lost* proved, would certainly therefore have been dissatisfied with Godwin's demonstration; but as the vehicle of a series of most touching and impressive scenes, his plot is far from deficient in interest, nor, granting its premises, in probability. "How minute," says an eloquent critic, "how pathetic, how tragical is the detail of the gradual ruin which falls on this weak devoted man, up to its heart-breaking consummation in the death of the noble Marguerite de Damville; how tremendous and perfect is the desolation, after voluntarily leaving his daughters, and cutting the last thread which binds him to his kind! How complete is the description of his escape from the procession of the auto da fé; of his entrance into the Jew's house, his fears, his decaying strength, just serving to make up the life-restoring elixir, the dying taper, the insensibility, the resurrection to new life, and the day-spring of his young manhood! How shall we speak of the old man, the bequeather of the fatal legacy to St. Leon, and his fearful words: 'Friendless, friendless! alone,

alone!' Alas! how terrible to imagine a being in possession of such endowments, who could bring himself to think of death!—able to turn back upon his path and meet immortal youth, to see again the morning of his day, and find, in renewed life and beauty, a disguise impenetrable to his former enemies; yet, in the sadness of his experience, so dreading the mistakes and persecutions of his fellow-men, as to choose rather to lie down with the worm and seek oblivion in the seats of rottenness and corruption."

Fleetwood.
Mandeville.
Cloudesley.

None of Godwin's other tales have been popular. "His man of feeling feels but for himself;" and, indeed, the character is in some points so unintelligible, and in others so odious, that notwithstanding many beauties of detail, we cannot wonder at the unpopularity of *Fleetwood.* The same sort of objections apply to the insane vindictiveness of *Mandeville.* *Cloudesley*, the child of Godwin's old age, is only remarkable for the gentle beauty of the style, and the contrast which the calmness of the story (turning, like *Caleb Williams*, on the discovery of a murder,) presents to the rapidity and sullen energy of his first production.

Brown.

No writer has come so near the manner of Godwin as Charles Brockden Brown, an American novelist, an imitator of the English author, but in a free and noble spirit of imitation. He certainly had not Godwin's power of mental analysis, and not much of that pathetic tenderness which, contrasted with the general sternness of his tone, shews like a rainbow against a troubled sky. He was altogether more prosaic; dealing, indeed, rather with the material than the moral sublime; producing his strong effects by scenes of sickness, danger, death, or the explosions of insanity; and often making his characters mere *phantasmata*, which interest us only as the means by which a series of agitating incidents are brought into connexion. But he had a good deal of the same eloquence, and the same dark and mysterious power of imagination; a certain intensity of portraiture, whether of mental emotion or things external; great skill in working up a chain of singular events that keep curiosity and suspense upon the stretch, or impress us with a sense of danger and anxiety, and of which he loves to furnish an explanation from those phenomena in our nature which are little understood, such as somnambulism, trances, spontaneous combustion, or ventriloquism. In these respects *Wieland, Ormond, Edgar Huntly*, and *Arthur Mervyn* have all nearly the same character, nor do they differ materially in point of merit. Brown has singular power in the delineation of solitude of all kinds, whether the silence of lonely forests, broken only by the howl of panthers, or of deserted mansions dropping to decay. There is one picture of this kind in *Arthur Mervyn*, of an empty house, evacuated during the yellow fever in Philadelphia, silent and dark in the day time, with the sunshine streaming in through the closed doors and shutters, and faintly discovering that every thing remained undisturbed since its desertion, which produces a strong feeling of awe, and oppresses the spirits with an unaccountable sadness.

Mrs. Shelley.

No other novelist of any ability can be said to have adopted the manner of Godwin with success, except his accomplished daughter, the authoress of *Frankenstein*, a production of much originality in its conception, though the execution of the work is unequal, and the whole portion which relates to the self-education of the monster, who is the creation of the new Prometheus, almost ludicrously improbable.

Several female novelists, towards the close of the eighteenth century, deserve notice, whose tales, though now little read, have the merit either of pathetic or humorous delineation. In the first of these classes are Mrs. Inchbald and Charlotte Smith; in the latter Madame D'Arblay, or to use the name by which she was best known, Miss Burney.

The fame of Mrs. Inchbald rests upon her *Simple Story.* The title perhaps is but of doubtful application to a novel, which is really complicated with strong and varied passions, which turns on the fate and fortunes of persons placed in very peculiar relations to each other, and like Shakspeare's *Winter's Tale*, unites two distinct stories relating to different personages, between the action of which "time has slid o'er sixteen years;" for the Perdita of Mrs. Inchbald's second part is the daughter of that Lady Elmwood, for whose misfortunes and indiscretions our sympathies had been engaged in the first, and who, almost in a sentence, is suddenly consigned to guilt, and to the grave. Dorriforth only remains the connecting link between the two portions of the tale. It is a proof of considerable merit in the novel, that so hazardous an experiment as that of transferring our sympathies to actors in a great measure new to the scene, has not been unsuccessful; that the interest is, notwithstanding, kept up, partly by the real pathos of some of the scenes, and the natural traits of passion in others, such as that where Lord Elmwood, receiving his deserted daughter as she falls into his arms, calls her by the maiden name of her guilty mother, as if all that passed since those days of innocence had faded from his mind like a dream; and partly by the dramatic nature of the situations which, though sometimes violent, are generally picturesque and agitating, and the movement of the dialogue, which every where shows the skill of a practical writer for the stage. Her second novel, entitled *Nature and Art*, has been generally and justly reckoned much inferior to the *Simple Story.*

The Si
Story.

Charlotte Smith.

Charlotte Smith, (1749—1806) though her novels are extremely defective in plot, betraying marks of haste, and tinged with a melancholy easily to be accounted for from the depressing circumstances under which they were generally composed, cannot be confounded with the ordinary day-labourers for the circulating library, "who turn a Persian tale for half a crown." Sir Walter Scott, in one of those kindly notices by which he delighted to cheer the heart of struggling genius, or to do justice to the memory of talents which time was consigning somewhat too rapidly to oblivion, has given her credit for great powers of satire mixed with pathos, and characters sketched with "firmness of pencil and liveliness of colouring." The satire indeed seems to have been pretty indiscriminate, since it extends to her own husband, whose pecuniary improvidence and sanguine temperament are glanced at in the character of the projector, who hoped to make a fortune by manuring his estate with old wigs. But apart from satire, the *Old Manor House*, the only one of her novels with which we are acquainted, is really entitled to the character of an interesting and well-written tale. We have a lively recollection of the *Manor House* itself, its neighbourhood, its sea-side scenes, the strange domineering Lady of the Manor, Mrs. Rayland, whom Sir Walter Scott describes as a sort of Queen Elizabeth in private life, and the natural interest which she has succeeded in giving to the love story which is going on within the ancient walls.

Old Man
House.

Miss Bu-
ney.

The popularity once enjoyed by the novels of Miss Burney, appears now to have been somewhat overrated, at least we are at a loss to discover any thing in her first work, *Evelina*, except the extreme youth of the writer, then only eighteen, to account for that burst of approbation with which it appears to have been received in 1778 by such men as Burke, Reynolds, and Johnson. She wrote no doubt with sprightliness, with some humour of a broad and superficial kind, and undoubtedly possessed considerable talent in drawing bores and personages of low manners or odd habits from vulgar middle life; in imagining scenes of awkward mistakes in society, and exaggerating the teasing distresses thence arising to her heroines and other personages of more refined manners or higher pretensions. Indeed, to mimickry she appears, from her father's account, to have had a strong leaning from her childhood; but when she rises from mere manners and habits to paint feelings, we see little but indecision on one hand, or exaggeration on the other. Within the field where she excels too, she is much of a mannerist; the same characters under other names, the same incidents under a thin disguise, re-appear in *Evelina, Cecilia,* and *Camilla.* Even the graces of style which she had shewn in her earlier works, in a great measure forsook her in her last novel, the *Wanderer;* a tissue of improbable distresses and silly refinements of sensibility, conveyed in language which is neither good English nor good sense.

Miss Lee.

The *Canterbury Tales* deserve notice on account of the interesting and highly original story of Kruitzner, or the German's Tale, by Harriet Lee, on which Lord Byron founded his *Werner.* The tales contributed to the work by her sister Sophia, such as the Two Emilys, and the Clergyman's Tale, though less striking, are written with genuine feeling and tenderness.

Miss Austin.

It may be observed, however, in those female novelists to whom we have last adverted that, though the marvellous is thrown aside, and the characters are taken from common life, the sentiments and tone of feeling are yet decidedly strained beyond the natural pitch. The characters display a degree of romantic affection and a prodigal expenditure of sensibility for which the cares and distractions of real life, we fear, afford but little leisure. It remained for Miss Austin (1775-1817,) to shew what a charm might be imparted to truthful pictures of life, as we really see it around us in the quiet monotony of domestic arrangements, with its interchanges of poetry and prose, business and strong feeling, and dialogues at balls and parties alternating with the secret griefs of the heart; just such a picture, in short, as Asmodeus would present, could he remove the roof of many an English home, and place us beside the hearths of the Knightleys, Bennets, Woodhouses, and Bertrams by whom they are inhabited. No species of novel writing exposes itself to a severer trial, since it not only resigns all Bayes' pretensions "to elevate the imagination and bring you off in some extraordinary way," but by professing to give us pictures of our ordinary acquaintances, in their common garb, places its productions within that range of criticism, where all are equally judges, and where Crispin is entitled to dictate to Apelles. And yet with such fine perception and perfect truth of keeping has Miss Austin performed her task, that we never miss in her novels the excitement of uncommon events, and rarely feel her simple annals of English life to be tedious or unworthy of the dignity of fiction. In reading them, we have the feeling of being actually in company with a group of highly respectable persons, of no remarkable ability, though with good sense and a fair proportion of right feeling; with a sprinkling of fools, oddities, and village gossips; and the conversation, the little incidents, and displays of temper, and sallies of good humour or bad, and small plottings and counter-plottings among the guests, are exactly such as any contemplative Jaquez who should establish himself in an English country house or rectory for a fortnight, and watch the bye play of the society about him, might set down in his note book; only skilfully selected and arranged, the superfluities lopped off, the dullness thrown into the background, and the whole wrought up into a picture, painted indeed in sober hues, but with unequalled delicacy of touch, and an all-pervading harmony.

All the novels of Miss Austin closely resemble each other; but *Northanger Abbey,* and *Sense and Sensibility,* are of a more puerile cast than the others, and betray a more unformed taste. *Pride and Prejudice,* particularly in the characters of the Bennets, was an improvement on the two former, but *Emma, Mansfield Park,* and *Persuasion* are justly regarded as her most finished works. Some scenes in *Persuasion,* the last work of this gifted authoress, have always appeared to us models of unobtrusive tenderness.

Miss Edgeworth.

Some one has described the novels of Miss Edgeworth as a sort of essence of common sense; and the definition is not inappropriate, for she is the most anti-sentimental of novelists. The sway of the stronger passions she has almost excluded from her Tales. Love is indeed the only one which has found entrance, and to qualify him for admission, his wings have been sorely clipped and trimmed, and reason constantly placed as a gentleman usher over him. Miss Edgeworth has even less toleration for splendid faults or bursts of enthusiasm than Miss Austin. Her chief aim is to rebuke folly, by ridicule and comic humour; to unteach bad habits of mind, to substitute in their stead prudence, firmness, temper, perseverance, and habits of absolute truth, a process which she generally represents as effected by a gradual series of efforts and consequent ameliorations, which are within the power of all minds of ordinary resolution. Her favourite characters are either persons of well-balanced minds, with sound heads and a smattering of physical science, who act rightly and honourably, but always think twice before they act, and weigh in the scales of utility what are generally considered as matters of feeling, like the Percys: or they are personages who, spoiled by indolence and bad education, succeed by a course of self-discipline, in curing their intellectual or moral maladies, and becoming useful and honourable members of society, like the hero of *Ennui,* Lord Glenthorn. Miss Edgeworth brings to her task the results of much observation of character, particularly that of her countrymen; a quick perception of the humourous, a dramatic liveliness of dialogue, a high sense of all that is honourable and decorous, with a scorn of meanness and evasion, and that tone of good society, which her pictures, often drawn from fashionable life, demand. If her novels are at times too obviously monitory and didactic, and the ferule peeps out rather alarmingly behind the schoolmistress, this defect, we fear, is in a great measure inseparable from the very qualities which constitute the strength of her mind, and from the conception she had formed for herself of the ideal of novel writing.

It is singular that a novelist of this rationalizing spirit, and so intolerant of all moral marvels, should have so frequently admitted great improbabilities into her plots, where the catastrophe is often brought about either by some one very unlikely event, or by a concurrence of events, and fortunate accidents, the combination of which render the circumstance at the least passing strange. Miss Edgeworth is also fond of making the discovery of important events turn on little trifles of circumstantial evidence, which are too artificially prepared, and after all are not satisfactory.

The impression, however, which the perusal of her best novels, such as *Ennui* and the *Absentee,* leaves on the mind, is that of high respect for the sagacity, grasp of mind and rectitude of judgment of the author, whose power of dramatizing a moral lesson has not often been excelled. And it is gratifying to see that, in the last work of Miss Edgeworth, *Helen,* there appears no diminution of her powers. In wit it is equal to any of her former novels; in pathetic scenes, superior to most of them.

Sir Walter Scott.

At the period when Sir Walter Scott (1814), produced the first of that long file of romances which have since obtained a more than European reputation, the public taste, in regard to novel writing, seemed to have sunk to a low ebb. Miss Edgeworth indeed was popular; for the wit and good sense of her dialogue, and her happy pictures of Irish character, found favour in the sight even of the readers of circulating libraries; but the merits of Miss Austin's more unobtrusive pictures of life were comparatively unknown. At best she was confounded with the writers of Winters in London, or Winters in Paris, and shared a dubious favour with the romantic effusions of Francis Lathom and the other labourers of the *Minerva* press, so called, we presume, upon the *lucus a non lucendo* principle, from the goddess of wisdom having so little to do with its productions. Translations, too, from Augustus La Fontaine's homely but rather vulgar pictures of little German *Kräh-winkel* towns, or the broad and indecent extravagances of Pigault le Brun, tended still further to degrade and vulgarize the public taste. Every thing in fiction, in short, looked unpromising and exhausted. The appearance of a great writer, who should strike out a new path through this much trodden waste, seemed at that moment in the highest degree improbable. And yet this was at once effected by the Author of Waverley, in such a manner as to raise the romance from the lowest level to the very highest position in literature.

Nothing, we believe, could be more irksome or more useless than to enter on any formal criticism of the romances of Scott; and it may well be doubted whether the present generation be in a condition to judge of his merits with perfect impartiality, or to determine his precise rank as a writer of fiction. We at least shall not allow ourselves to be seduced into such a disquisition, but shall confine our observations to a few points on which we think it hardly probable that posterity will reverse the concurrent judgment of the present day.

The resemblance of Scott's mind to that of Shakspeare has been often remarked, and with some justice; for though even the most enthusiastic admirers of the romance writer, will hardly venture to claim for him an equality of powers with Shakspeare, there were strong kindred features in the character of their minds. In both we are struck with the same general and almost universal sympathies, leading to impartial and kindly views of all men and all opinions, the most remote from their own; a cheerful, healthful tone of feeling, which brightens existence about us, instead of dwelling on its evils; an avoidance of all moral casuistry, or treading on the borders of the forbidden, either in the creation of characters or of incidents; the feeling of the humourous as strongly developed as the sensibilities or the imagination; great self-possession, and a noiseless exertion of power, working out its end, not by sudden bursts, or high-wrought passages, but by a silent and steady progression, like the dawn brightening into the fulness of day.

The works of Scott produce their effect rather by the combination of many qualities than the predominance of any. In depth of feeling, we think he yields to the author of *Anastasius;* in invention of incident, and disposition of plot, he is equalled by many; his humour will hardly bear a comparison with that of Sterne, or the best parts of Fielding; and in the direct and forcible expression of the stronger passions, we should be inclined to give the preference both to Godwin and the author of *Valerius.* But his strength lies in the possession and harmonious adjustment of most of the qualities requisite to the novelist, none engrossing the whole mind, none excluding another, but all working together in kindly unison: learning arrayed in the most picturesque combinations; observation of life embodied not in abstractions, but in living forms; humour springing out of tenderness, like smiles struggling through tears; the spirit of ancient knighthood leavening the worldly wisdom of modern times; and the imagination of the poet adorning, without impairing the common sympathies and good-humoured sagacity of the man.

The department in which this combination of qualities has been most successfully displayed by Scott, was that of the historical romance,—a class of fictions which he may truly be said to have created. For although fictions bearing the title of historical romances, were by no means uncommon in English literature before the time of Scott, such as the *Recess* of Miss Lee, or the *Scottish Chiefs* of Miss Porter, it is apparent that they stand in a totally different class; not being, in fact, historical, except in the names of the characters. Obvious as the idea now appears, Scott was in truth, the first to show how much invention might gain by a union with reality; what additional probability, interest, and importance might be given to the fortunes of imaginary heroes, by interweaving their destinies with those of historical personages; nay, how much of romance in its finest forms lies in the characters and events of history itself invisible to the prosaic or merely philosophic observer, but obvious at once to the eye of imagination. He has carried the picturesque of history to its perfection; for without imparting to his portraits the deep and subtle traits by which Shakspeare so wonderfully individualizes the beings of his dramas, he never fails at least to present consistent and striking pictures of his historical personages in their habit as they lived, and to dispose the light and shadow about them with the most felicitous adjustment,—dress, look, gestures, manner, and the outward accompaniments of scenery, being all made important accessories, to heighten the effect of well-known peculiarities, or to hide the want of those over which Time has dropped a veil, which even Imagination can hardly raise.

In description, indeed, generally, Sir Walter Scott was unrivalled. Whatever he sees with the eye of the mind, shapes itself into words which enable us to see it too. His pictures combine in a singular way breadth and minuteness; for while he painted the details with sharpness and firmness, no one understood better the art of arrangement in masses; so that he never fails to give the spirit as well as the form of the spot, making us *feel* the solemnity and gloom of castles and druidical forests, the calm produced by the still beauty of a Highland lake, from which the morning mist is disappearing, or the healthy elevation of spirits with which we travel up some mountain height, whence we see far into the country beyond, and "feel the breath of heaven fresh blowing."

We offer no remarks upon his characters, except this, that making every allowance for repetitions, no writer of fiction since Shakespeare has enriched the portrait gallery of invention with more originals, of which we have a distinct conception; and that though his female characters have less variety and less truth than his male personages, we know no writer except Shakspeare to whom the same remark may not justly be applied.

The plots of Scott, speaking generally, are neither remarkable for excellence, nor the reverse. Examples may, in fact, be found, in the long list of his romances, both of skilful and defective plots. *Ivanhoe*, *Kenilworth*, and the *Bride of Lamermoor*, for instance, are proofs how artfully he could at times arrange his plan; the two latter having all the compactness and steady progression of the drama. Others, again, such as *The Monastery*, *St. Ronan's Well*, and *Rob Roy*, are in a high degree loose and inconsequential.

Fertile and inventive as was the genius of Scott, it cannot, we think, be denied, that during the latter half of his career as a writer of fiction, he appeared to less advantage. No wonder, indeed, when, in addition to the limits by which all invention is bounded, we consider under what depressing circumstances many of his later works were composed, that in these even the elasticity of genius itself should be somewhat outworn and deadened; that the conventional, both in character and incident, should occasionally supply the place of invention; and that mere imagery, and not always very appropriate illustration, should be substituted for the natural turns which at first enlivened the dialogue. "If there be a mental drudgery," to use his own words in his notice of Charlotte Smith, "which lowers the spirits and lacerates the nerves like the toil of the slave, it is that which is exacted by literary composition, when the heart is not in unison with the work on which the head is employed." When he breaks up new ground, as in *Nigel*, *Quentin Durward*, and *The Crusaders*, his genius indeed suffers little diminution; but in *Redgauntlet*, *Anne of Gierstein*, and *The Betrothed*, the practised skill of the mechanist, recomposing old materials in new shapes, is far more visible than the freshness and spontaniety of an original inspiration. With the publication of *Kenilworth*, indeed, the sun of his fame may be said to have "touched the highest point of all its greatness;" but like that luminary during a polar summer, it seemed for a time rather to revolve than to descend, and its rays continued to look bright and beautiful, long after it was journeying towards the west.

No writer ever exercised so great an influence over the public mind, or led to so much conscious or unconscious imitation. His influence on Italy, France, and Germany, we shall afterwards have occasion to notice. On the literature of Great Britain, we believe it to have exerted on the whole a most beneficial effect; not, indeed, that any professed imitation of his manner has yet appeared, which possesses great claims to genius, but that he has carried a higher spirit into novel writing; taught us how the simple feelings of peasants, and the homely pathos of humble life, and the relentings of feeling amongst the outcasts of society, might be made to blend with scenes of high imagination; that his writings are calculated to strengthen the ties of our common humanity; that they never tend to foster a bad, or to throw ridicule upon a good or generous feeling; while, speaking of them in a merely literary point of view, they taught lessons of simplicity, good taste, moderation, and skill in seizing the best points both of character and description, which have not been without their effect even on those by whom the mere manner of Scott, or his choice of subjects, have been studiously avoided.

The professed imitators of Scott have been numerous, but not successful. As usual, they have magnified his defects, urging his conventional personages, such as dwarfs, fools, gypsies, and bores, into caricature; multiplying instead of retrenching those similes which, even in the original, were so obtrusively frequent, as to remind us of Bayes' rule for writing dialogue, "ever make a simile when you are surprised;" and overlaying the plot with minute descriptions of dress and scenery, which the reader, after a little experience, is wise enough to avoid. In reading them we are constantly reminded of Boileau's description of a tedious poetical landscape painter:

> S'il rencontre un palais il m'en decrit la face
> Il me promene apres de terrasse en terrasse,
> Je saute vingt feuillets pour en trouver la fin,
> Et je me sauve a peine au travers du jardin.

es and
per.

The best imitation of Sir Walter Scott's manner with which we are acquainted is the anonymous romance of *Forman*, of which he speaks with respect in his criticism on Mrs. Radcliffe. The romances of Mr. James, too, though not indicating much depth, are pleasing, always written with good feeling, and with a plot which excites a sort of quiet interest, if it does not keep the mind in the chain of curiosity or suspense. The novels of Cooper, who is probably better known than any other of the imitators of Scott, seem to be considerably overrated. On shipboard, or on an Indian heath, he is striking and picturesque; but among civilized society, and, above all, in his attempts to catch the ease of fashion, we must regard him as singularly unsuccessful.

A strange contrast to the spirit of Scott's novels was exhibited in the sceptical and dreary tone of *Anastasius*. Without force of character-painting, with much languor in parts, and too prolonged a detail of heartlessness and villany, the work fascinates by its strength, and towards the close, when the character of the hero deepens, by its irresistible pathos. Commencing with the levity of a Greek Gil Blas, it modulates into a key of sadness and desolation of spirit, which reminds us of the close of *St. Leon*. Fiction has few pictures which will bear comparison with that of *Anastasius*, sitting on the steps of the lazaretto of Trieste, with his dying boy in his arms; and the whole conclusion of the romance, the sudden meeting and silent parting with Spiridion, the journey towards the north, the dream, the warning voice, which, in the dusky light of daybreak, tells him he has not far to go; the hopelessness, the resignation of his death, all leave on the mind that profound impression of the mutability and nothingness of existence, which Wordsworth has described:

> So fades, so languishes, grows dim and dies,
> All that this world is proud of. From their seats
> The stars of human glory are cast down,
> Perish the roses and the crowns of kings.

It is not our intention to pursue this sketch through the works of our living ornaments of the literature of fiction, or of some who have recently been taken from amongst us. We shall merely notice, that among those who have struck out an independent path for themselves, are the author of *Valerius* and *Adam Blair*, works of conspicuous originality, particularly the first, in which the difficult task of imparting a deep interest to a classical subject is performed with complete success; the author of the *Trials of Margaret Lindsay*, and the *Lights and Shadows of Scottish Life*, who, with the finest feeling of the dignity and poetry which lie within the humble rural life of Scotland, has performed for its more pathetic and elevated aspect, what Galt, in his *Annals of the Parish*, and his other tales, has done for its humours and its vulgarities; the authoress of *Marriage*, the *Inheritance*, and *Destiny*, and Sir E. L. Bulwer, who has given proof of very versatile ability, in a series of romances widely differing in character, from the levity of *Pelham* down to the earnestness of *Maltravers*, but the best of which we think his more matured taste and judgment may yet surpass.

Italian Romance.

No country has produced more novelists than Italy; but the Italian novel bears little analogy to what we understand by the term. Their novels were, in fact, originally prose versions of the same short tales, sometimes heroic, but more frequently turning on themes of gallantry or comic adventure, which formed the favourite subjects of the Trouveres. They were Fabliaux translated into Italian; and this character they retained for five centuries from Boccaccio to Gozzi. (1313—1786.) The incidents are generally briefly given; there is little development of character or sentiment; or, where these are found, they exhibit rather separate scenes from life than any thing having the interest of a compact whole. But if the incidents and characters have little development, the Italian novelists have indemnified themselves for this confinement, by indulging in the utmost license of a pompous, circuitous, and unmeaning style. The facile beauty of the Italian language, "Che spande di *parlar* si *largo* fiume," has been the bane of their novelists. Boccaccio, the first and by far the greatest of the Italian novelists, indeed manages to impart to it a sort of garrulous grace; but in the hands of his imitators the contrast between the poverty of the idea and the rich garb of words with which it is invested, assumes a ludicrous effect.

Never, perhaps, among so many novelists, was there so little of novelty. Instead of imitating nature, their avowed principle was to imitate Boccaccio, who, imparting to every thing a soft and rose-coloured glow, was himself not remarkable for the closeness of his adherence to it. And hence regarding the novel merely as a theme upon which they were to display all the brilliant variations of which the music of Italian speech was susceptible, they were contented to repeat in a great measure the same themes, to borrow, with a sort of easy impudence, their incidents from Boccaccio or from each other; and more anxious for the purity of their Tuscan than of their tales, of which by far the greater number turn on scenes of licentiousness or low humour, they seemed to think all other merits in the novel subordinate to that of being "written in very choice Italian."

Beyond the limits of Italy, Bandello (1554) and Cintio (whose *Hecatommithi* appeared in 1565,) are almost the only novelists whose names are known to foreigners, if we except the *Belphegor* of the versatile Macchiavelli; and the chief interest connected with these novelists consists in the hints or materials furnished by them to Shakspeare, Massinger, Beaumont and Fletcher, and our dramatic writers of the time of Elizabeth and James, to whom indeed these works, particularly those of Bandello, afforded a perfect storehouse for plots. Among the nine volumes of Bandello's works contained in the Novelliero, some interesting and a few pathetic tales may be pointed out; but Cintio's can have no interest in themselves except for those who love to sup full of horrors; for he was one of those wholesale dealers in the terrible, who thought that poetical effect was to be produced by a vigorous operation on the nerves rather than the feelings, and therefore piqued himself, like the schoolmaster in Gil Blas, on massacring all the personages of his tragedies, even to the prompter.

Towards the close of the last century, a taste for novels in a style somewhat resembling our own, appears to have gained ground, and several tales of a melancholy kind made their appearance. With these we do not profess to be acquainted; nor has any one which appeared prior to the *Promessi Sposi* of Manzoni, attained the least reputation beyond Italy, with the exception of the *Ultime Lettere di Jacopo Ortis*, an early production of Ugo Foscolo, (1802); and the result partly of a melancholy event occurring in his own family, and partly of the study of Goethe's *Werther*, by which the enthusiastic mind of Foscolo appears to have been very powerfully affected. Like *Werther*, it is a story of love and suicide, full of fervour, violence, and, to speak the truth, of absurdity; yet delivered with a species of eloquence, and a certain appearance of conviction, which, so far at least as regarded the expression of mental discomfort, and the misery arising from a total want of all fixed opinion, was perhaps sufficiently real. To the Italians, who knew little or nothing of Goethe, this stormy effervescence of an impassioned temperament, and all this eloquent "questioning of fate," possessed even an air of originality; and being the first successful attempt to introduce the sentimental romance of the school of Rousseau and Goethe into Italy, it naturally awakened a degree of enthusiasm which now appears somewhat disproportioned to its real merit.

The *Promessi Sposi* of Manzoni certainly approaches much more nearly to the idea of a good romance than any thing which Italy has yet produced; but, after all, it too is essentially an imitation. If we had had no Scott, we should have had no Manzoni. The idea of illustrating a subject connected with the Italian history of the commencement of the seventeenth century; the introduction of historical characters, such as that of Cardinal Borromeo, who is the *deus ex machina* of the piece; the antiquarian lore displayed in the way in which the bread-riot in Milan (a close parallel to the insurrection of the Liegeois in *Quentin Durward*), is wrought up; the account of the plague in the Milanese, in which Manzoni has tried to imitate at once Boccacio and Scott,—all concur to satisfy us, that Manzoni, though an able lyric poet, has no great share of original invention, and that though he can make a good use of materials furnished by others, he is one of those literary commercialists who require to borrow the main portion of the capital with which they are to trade. We are far, however, from denying the real merits of this performance of Manzoni, in which the characters of Cardinal Borromeo, and the peasant hero and heroine, Renzo and Lucia, are naturally and pleasingly drawn, and in which some of the scenes, such as the opening scene at Don Abbondio's house, the riot in Milan, the interview between the unknown and the Cardinal, and some of the incidents and descriptions connected with the plague, are of vivid interest.

Since the appearance of the romance of Manzoni, who has lately abandoned both fiction and poetry for religion, many attempts have been made by Rosini, D'Azeglio, Guerazzi, Tommaseo, Belmonte, and others, to transfer the historical romance to an Italian soil, and to give a romantic interest to the delineation of the Italian feudal history of the middle ages, or of periods somewhat later. The first, and we believe the best, of these appears to be the *Monaca de Monza* of Rosini, who has founded his story on an episode in the *Promessi Sposi*. Were we to form a judgment from a few of these attempts which we have read, as to the merits of those of which we remain ignorant, we should be inclined to say generally, that nothing is more remarkable than the total want of interest which Italian subjects possess in Italian hands; a result which appears the more singular, since at one time it was only necessary in our English romances to transfer the scene to Italy, to enlist at once our warmest sympathies in favour of the story. Now-a-days, we think, when the subject is almost entirely in the hands of native novel-writers, the very idea of embarking on an Italian story of the middle ages, seems to act upon the fancy as the most powerful refrigerative. Strangely enough, too, it is to be observed, that the Italian novelists of modern times never appear to greater advantage than in the description of the most furious battles, carried on with all the determination and bloody-mindedness of an Esplandian or a Bobadil, as in *Ettore Fieramosca*, by Massimo D'Azeglio, a son-in-law of Manzoni, or *L'Assedio di Firenze*, by Gualandi; an expenditure of valour on paper which we fear is scarcely justified by the fact, since, if we are to give credit to the accounts of Guacciardini, many of their most doughty encounters were as harmless in their results as the protracted passage of arms between Gymnast and Tripet, in *Rabelais*, as to which uncle Toby, after listening to an endless detail of the various complicated manœuvres, declared, that one home-thrust of the bayonet would have been worth them all.

Spanish romance.

In Spain, which, though not the birth-place, had certainly become by adoption pre-eminently the country of the chivalrous romance, and where, perhaps, its extravagances had been less redeemed by talent than any where else, it is well known that a revolution in taste was effected by the inimitable satire of Cervantes, (1547–1616), which Montesquieu, with amusing extravagance, describes as the single admirable book in the Spanish language which shews the absurdity of all the rest. So effectually, indeed, did that work (published in 1605) attain its end, or rather one of its ends, that after its appearance no romance of chivalry appeared in Spain, and the old ones so entirely ceased to be printed, that it is with difficulty that copies of them are now to be obtained. The "ultimus Romanorum," the last adherent of the good old romance, was Don Juan de Silva y Toledo, who published his *Don Policisnè de Boecia* in 1602, three years before the appearance of the *Don Quixote*.

Cervan Don Q ote.

But, had that book been solely devoted to the object of exploding the old romances of chivalry, it would probably have shortly been forgotten with the extravagances it exposed. The charm which has given a perennial life and continued popularity to *Don Quixote*, is the deeper idea which it contains of illustrating, in comic colours, the contest between imagination and reality; the danger, both to its possessor and to others, of all misdirected enthusiasm, whether it take the direction of reviving an extinct age of chivalry, or any other course plainly running counter to the current of society all around it, by means of which a constant collision is produced, in which, whatever becomes of the world, the visionary himself is sure to be the sufferer. For the fuller development of this idea, he has placed beside the knight, who represents the imagination without the common sense, a squire who is the type of the vulgar common sense without the imagination. Between these children of his brain, he parcels out the treasures of his mind, bequeathing to the knight his own high spirit and courage, his learning, his generosity, and his love of truth;

and to the squire the solid riches of his good sense, and his peculiar humour; that humour, which, as it exists in Cervantes, is among the rarest of human qualities,—the very poetry of the comic, founded on tender sympathy with all forms of existence, though displaying itself in sportive reflection; and issuing not in superficial laughter, but in still smiles, the source of which lies far deeper.

The characters and fortunes of these contrasted companions he has linked together in such a way, as to impress on the mind the feeling, how indispensable each is to each, as the complement of the other,—the learning, highmindedness, and strong imagination of the knight being indispensable as the creative and moving power in human life; the practical good sense, and even selfishness, of the squire as the controlling force; from the judicious union of which opposites arises the harmony, and from their separation the discords of society. He paints also, with great knowledge of human life, the effect which these reciprocal influences, constantly exerted on each other through vicinity and a common pursuit, have in modifying even the original character itself, and gradually making the enthusiast more rational, and the common-place man of the world more imaginative. The sound philosophy, the impartial and kindly spirit with which Cervantes has wrought out this conception, in which justice is done at once to the higher and the more common elements of our nature; the flood of humour with which he surrounded it,—which has tempted many a one since the days of Philip IV. to imitate the pantomime of the student on the banks of the Manzanares,—are as obvious to the least refined of readers, as they are models of art worthy of the admiration and profound study of every writer of fiction. Like human life itself, the story unites and harmonizes the opposite extremes of the pathetic and the ludicrous, the vulgar and the elevated,—for from the midst of the comic ground-work, the striking scenes in the Sierra Morena, the episode of Cardenio and Dorothea, the story of the captive, the sweet pastoral of Marcelia, the marriage of Camacho, and many other passages, rise up, rich in pathos, grandeur, or imagination; so that, in fact, there is no work in which, while the aim at first might appear to be to destroy the romance of life, passages of more purely romantic beauty are to be found. The truth is, that Cervantes, though anxious to explode a vicious taste in literature, was far enough from wishing to direct his satire against the creations of high imagination, or against the spirit of chivalry. The admiration he expressed for Amadis and Palmerin shews, that he was not insensible to the beauties by which even this branch of literature was occasionally redeemed. His own adventurous career of glory and misfortune had, no doubt, deeply impressed upon his mind the contrast between the dreams of imagination and the realities of life; he saw the poetical capabilities which such a contrast afforded,—and he has painted them with an unshrinking, and some may think a merciless hand. But, even beneath the veil of ridicule with which he has invested his crazed and battered hero, we perceive his own unextinguishable love of the exalted principles by which he is actuated; and the abiding impression which remains with us after the comic effect of the romance has passed away, is, that truth and nobleness of character will continue to command our love and veneration, though displayed in actions with which the world cannot sympathize, and placing their possessor in situations which excite our ridicule, even while his motives attract our admiration.

N elas E mpla- re

Cervantes seems to have intended his moral novels, *(Novelas Exemplares)*, to be to Spain what the short tales of Boccaccio and his followers had been to Italy, only with the advantage of a purer morality. They are unequal; some being mere satirical trifles, such as the *Licentiado Vidriera;* others, like the *Jealous Estremaduran*, (which English readers will recognize in the common farce of the Padlock), the *Gipsy*, and the *Spanish English Lady*, highly interesting in themselves, and characteristic of Spanish manners, laying open to us, as Sismondi says, the hearts and houses of its inhabitants. One novel, the *Tia fingida*, (Pretended Aunt,) though undoubtedly written by Cervantes, was not included in the original collection, probably from the disagreeable nature of the subject.

Persiles and Sigismunda.

The remaining work of fiction by Cervantes, the *Persiles* and *Sigismunda*, is only remarkable as the last work which he wrote, and as being quite as absurd and extravagant as any of those romances of chivalry against which his powerful satire had been directed. No work has occasioned a greater division of opinion. While some of the Spanish critics speak of it in terms of extravagant praise, it is described by Viardot, a French critic, as "a tissue of episodes interlaced with each other, like those of one of Calderon's intrigues, consisting of extravagant adventures, silly rencontres, astounding prodigies, preposterous characters, and extravagant sentiments." It retains little or nothing, indeed, of Cervantes, but the charm of his style. Yet, like Corneille placing his *Nicomede* before the *Cid*, or Milton his *Paradise Regained* before his *Paradise Lost*, Cervantes seems to have given the preference to this child of his old age over the master-piece of his manhood.

Lope and the Spanish novelists.

The fashion of short novels in the Italian taste, which had been introduced by Cervantes, was followed by Lope, Canizares, Zayas, Montalvan, and by a host of imitators, whose very names the Spanish critic Lampillas declares that he is unable to enumerate. The loss of the catalogue is little to be regretted; for even among the names which are known, it would be difficult to point out one, even including the great Lope, which rises above mediocrity. Nature, indeed, seems to have given Cervantes his revenge, for the triumph of his rival in the drama, by the failure of Lope as a novelist,—for in this department, the talent and rich invention which he displayed on the stage appeared in a great measure to desert him. The best of his novels is the *Fortunas de Diana*, (Fortunes of Diana), first printed in the Filomena in 1621; next to which we should place his *El Zeloso hasta Morir*, (Jealousy till death); but truth to say, neither are remarkable. Indeed, if we except Cervantes, the same remark which we have ventured to make on Lope is generally applicable to the Spanish novelists. Nearly in proportion to the success of the nation in the creation of an original drama, is its signal deficiency in original contributions to the literature of romance. It is not often, indeed, as Tieck remarks in his preface to Bulow's *Novellenbuch*,[1] that the dramatic and novellistic power are found combined in a national literature to the same extent as in England.

Romances in the Gusto Picaresco.

In fact, the only species of prose fiction, with the exception of *Don Quixote*, in which the Spaniards have displayed any thing like original invention, is in the novels written in what is called the *Gusto Picaresco*, or the romances of roguery, of which the first example of any merit, and, with one exception, the best of the whole series, was furnished by the *Lazaro de Tormes* of the celebrated Don Diego de Mendoza, and is said to have been written by him while a student at Salamanca, and first printed in 1553. It is rather singular, no doubt, to find a man of rank devoting himself to these pictures of want and miserable knavery, or a nation affecting so much external pomp and ceremony relishing these exposures of the real filth, meanness, or starvation which often lurked under the cloak of the whiskered Knight of Calatrava. But the Spanish character is distin-

Mendoza.

---

[1] Das Novellenbuch, oder hundert Novellen nach alten Italienischen, Spanischen, Franzosichen, Lateinischen, Englischen, und Deutschen, bearbeitet von Eduard von Bulow. Leipzig, 1834. An excellent authology, from the shorter literature of romance in the above languages; and not a mere translation, but in many cases a dexterous rificciamento, true to the spirit, while avoiding the dullness or indecency of the original.

guished by a very peculiar vein of dry humour intermingled with a tinge of orientalism in their notions of birth and pride of ancestry and personal dignity, and hence the Spanish novelists seem to have been perfectly alive to the ridiculous features of their countrymen, while sharing very probably in the same exaggerated pretensions themselves. Accordingly, along with the adventures of rogues, and beggars, and gipsies, who, during the reigns of the Austrian Philips, appear to have literally swarmed in Madrid, are interspersed ample illustrations of this union of poverty and pride, and the stratagems with which many a pompous cavalier, walking the streets, as Lazaro says, like the Duke of Arcos, is occupied at home in order " to procure a crust of dry bread, and having eat it, to appear with due decorum in public, by the art of fitting on a ruffle so as to suggest the idea of a shirt, and adjusting a cloak in such a manner as to make it be believed there are clothes under it."[1] Mendoza's novel contains a sketch of one of these shirtless and famished hidalgos eagerly devouring some crusts which Lazaro had begged in the morning, on pretence of trying whether the bread was sufficiently wholesome, which gives an image of starvation, in which the painful is strangely blended with a sort of sombre gaiety.

Equal, if not superior to Mendoza's romance, is the *Gusman d'Alfarache* of Matteo Aleman (1599,) which, though dealing in the same gloomy pictures of want and misery, has more variety in its pictures, and a more severe and caustic character in its sarcasm. It has been erroneously supposed to have furnished many particulars to Gil Blas; in fact, it would be difficult to point out one, except the incident of the parasite who obtains a supper at the expense of the eighth wonder of the world. In the same taste is the *Gran Tacano of* Quevedo.

Espinel.

The merit of having supplied Le Sage with much of his materials, may be more plausibly claimed by Vicente Espinel, the author of the *Vida del Escudero Marcos de Obregon,* printed in 1618. Indeed, while the superior grace, spirit, and gay philosophy of Le Sage are apparent, it is impossible not to make a considerable deduction from his mere invention after reading the work of Espinel. The prologue, the adventure of the parasite, the dispersion of the company at Cacabelos by the muleteer, the adventure of the robber's cave, the surprise by the corsairs, the contributions levied by those pious hermits, Don Raphael and Ambrose de Lamela, the service with the Duke of Lerma, and many of the other incidents, have nearly an exact parallel in the ruder and drier work of Espinel. Even some of the witty points, which we might be disposed at first sight to believe were Le Sage's, turn out to be the property of the Spanish chaplain; such as Don Matthias de Silva's reply, when asked to fight a duel early in the morning, that he never rose before one, even for a party of pleasure, and could not be expected to rise at six to have his throat cut.

This much, however, must be said for Le Sage, that he shows no desire to conceal the source of his obligations, for one of his characters is termed Marcos Obrejon, and the Sangrado of his novel is, undisguisedly, the Sagredo of Espinel. Le Sage, however, knew that after every deduction was made on the score of invention, the merit of his novel would remain much the same. He threw lightness and sunshine into the mean and gloomy pictures of the Spaniards, taking care to efface the recollections of folly and knavery in his adventurers, by a cheerful and respectable termination of their career; and though the graduation of the fool into the knave, and the knave into the honest man, upon a mere principle of utility, be not perhaps in itself a very lofty moral, it is at all events far more agreeable than that of the Spanish novelists, where the rogue continues such to the last, and his only advancement is to a higher degree in the curriculum of knavery. A romance of a more pleasing and political cast than these tales of knavery, was the historical romance, the *Civil Wars of Granada*, by Gines Perez de la Heata, printed in 1604, turning on the dissensions of the Zagus and Abencerrages during the reign of Boabdil, and giving occasion, as might be expected, to many fine descriptions of tournaments, feasts of canes, Moorish palaces and gardens, and the contrast between the Christian and the Moorish chivalry. From this romance Florian has mainly borrowed the idea and materials of his *Gonsalvo of Cordova.*

One other work of fiction deserving notice, though partaking more of the nature of the satire than the novel, is the *Fray Gerundio* (Friar Gerund) of the Jesuit de l'Isla,—a severe, but rather tedious satire upon the absurdities and bad taste of the popular preachers of the time. In romantic literature the Spaniards at the present day seem to be entirely deficient. Translations of the popular French and English novels abound, but native talent or invention appear to be at an end.

French romances and novels.

In France the pastoral romances of D'Urfé and his imitators, and the heroic romances of Gomberville, Scudery, and Calprenede, whose object was "peindre Caton galant et Brutus dameret," were succeeded by an inundation of *contes des fees* and *voyages imaginaires*, appearing about the close of the seventeenth and the commencement of the eighteenth century. This species of nursery literature, which, like the character of the fair Arricidia in *Clelia*, was " furieusement extraordinaire et terriblement merveilleux," seemed peculiarly well suited to the frivolous tastes which then pervaded French society; and its temporary attraction was perhaps based in some degree upon the very want of reason and common sense, which rendered its permanent popularity impossible. When the sage Oglou in Voltaire asked the sultanas " comment preferez vous des contes que sont sans raison et que ne signifient rien," the answer of the sultanas was, " c'est precisement pour cela que nous les aimons."

Fairy tales.

Perrault.
D'Aulnoy.
Murat.
La Force.

The chief writers in this school of fiction, with whose compositions most of us have in our early days been rendered familiar, through the little gilded volumes of Mr. Newberry or his successors, were Perrault, the Countess D'Aulnoy, Madame Murat, and Mademoiselle de la Force, of whom Perrault is decidedly the best, his tales being distinguished by a simplicity and naivete of style indispensable in this style of writing, and in which the productions of the ladies are deficient. No great share of original invention is displayed by any of them. The chief storehouse from which they drew was the *Notti Piacevoli* of the Italian novelist Straparola, and the very remarkable Neapolitan collection by Giambattista Basile, entitled the *Pentamerone*, of which the first edition appeared in 1637.

A sightly different direction was given to this taste for marvels by the translation into French of the *Arabian Nights* by Galland, and of the *Persian Tales* by Petit de la Croix and Le Sage, which led to a host of oriental imitations. And the childishness and absurdity of the whole of this department of literature was exposed with great wit and liveliness by Count Antony Hamilton, in his *Fleur d'Epine*, and in his unfinished tale of the *Four Facardins.*

Marivaux.

But this same period was distinguished by the productions of some writers of a higher order: Marivaux, (1688—1763), Prevot, (1697—1763), and Le Sage, (1668—1746). Marivaux had a good deal of Richardson's power of delicate portrait painting, by an accumulation of miniature touches: nor is he deficient in the power of managing the interesting situations with which his *Mariamne* especially abounds. And certainly, if we except Mademoiselle La Fayette's pleasing romance of the *Princess of Cleves*, he may claim the merit of having been the first, in France, to reduce the novel from mere extravagance, both of incident and character, to the standard of natural feeling, and to present us with real beings, instead of fantastic creations of the imagination. His chief faults are his intolerable minuteness in trifles, and the affectation of the style, which is worthy of the society of the Hotel de Rambouillet. His best novel, too, the *Mariamne*, terminates abruptly and inartificially, with a conclusion like that of Zadig, "where nothing is concluded."

---

[1] Dunlop's *History of Fiction*, vol. iii. p. 119.

evot.

Prevot had a much higher and more romantic imagination than Marivaux. He threw into the novel something of the gloom and grandeur of tragedy; and hence he has been termed by some of his countrymen the Crebillon of romance. A visionary disposition and an ardent temperament had hurried him through a restless and passionate life, in which good and evil, suffering and enjoyment, had been scarcely blended; so that to the task of composition he brought the results of a mournful experience in aid of the resources of the imagination. To use the expression of Voltaire, "Il n'etait pas seulement un auteur mais un homme, ayant connu et senti les passions." Prevot is not a great inventor of character; for to all his heroes, Cleveland, Patrice, even the Chevalier des Grieux, he appears to have lent much of his own feelings and his own peculiarities of mind. Though an extremely voluminous novelist, none of his works appear now to be read or recollected, except his painful but powerful story of *Manon L'Escaut*, a tale of crime and profligacy, strangely blended with generous feeling, which has been translated into English by Charlotte Smith. *Manon L'Escaut*, though little more than an episode, thrown off apparently with an easy negligence, bears the impress of genius, which it would be difficult to recognise in an authentic form in any of the larger productions of Prevot. Opening in the most unpromising manner, with what appears to be the common-place history of a vicious and discreditable connexion between Des Grieux and Manon, in which weakness of principle on the one side is made the dupe of profligacy and vanity, united with personal charms, on the other, the stream of feeling, at first polluted and turbid, works itself purer as it runs; and the scenes rise into elevation just as the character of Manon herself, the "fair mischief" of the romance, around whom Prevot has thrown no common fascination, changes from the selfish mistress into the faithful companion, following the fortunes of her husband, whom her charms had ruined, into disgrace and banishment, and dying by his side among the wilds of America.

Madame de Tcin.

Love also forms the subject of the novels of Madame de Tencin, (died 1749), the *Siege of Calais* and the *Count de Comminges*, which are admired for their tenderness and delicacy, qualities we should hardly have anticipated from a lady who stood in so confidential a relation to the cardinal Dubois, and who left her illegitimate child, d'Alembert, to the tender mercies of the public.

L Sage.

The greatest of the French novelists, however, is Le Sage. Even in his first romance, the *Diable Boiteux*, the plan of which has been suggested by the *Diablo Cojuelo* of Luis Velez de la Guevara, and which appeared in 1707, the wit, the graceful lightness, and the good-humoured sagacity of observation, which distinguished the character of Le Sage, were evident. The conception, in particular, of his esprit follet, a "diable bon-homme," with so much more gaiety than malice, that at times we are tempted to think him rather amiable than otherwise, was a great improvement on Guevara's; and the effect of the work was heightened by the skill with which he contrived to interweave with the story, if such it can be called, a multitude of contemporary allusions. Such indeed was its popularity and immediate sale, that two young men are said to have fought a duel in a bookseller's shop about their right to the only remaining copy; a well attested anecdote, so much in the spirit of those satirical traits in which Asmodeus indulges, that as Sir Walter Scott remarks, it deserved to be recorded by the demon himself.

The reputation as a novelist which these most amusing revelations of Asmodeus had founded, was brought to its height by the production of the first three volumes of *Gil Blas*, bringing the history down to the retirement to Lirias; a work, with the exception of *Don Quixote*, perhaps the most universally popular in fictitious writing, pleasing equally, whether read in youth, in manhood, or in age, and containing, as has been justly said, more "useful knowledge," than twenty scientific and moral treatises. Le Sage's celebrated novel represents the level of life as it appears in a large capital, without either its brightest lights or its darkest shadows. He exhibits the average state of feeling among such communities,—loving virtue and good conduct within due bounds, but, at the same time, with that natural toleration for selfishness, servility, vanity, or occasional deviations from the path of strict integrity, which in such society is certain to be engendered and countenanced. As he saw nothing like an elevated morality in the world with which he was best acquainted,—the Parisian public,—so he has not attempted to introduce any such exalted tone of feeling into his romance. His hero is an adventurer, to whom a hundred parallels might probably have been pointed out any evening among the audiences at the Foire, with fair abilities, with a kindly heart, and naturally good inclinations, but little moral firmness; by no means so enamoured of the straight road of right as not to turn aside occasionally when the deviation suits his purposes; duped at first by his own vanity, and then availing himself of his dear-bought experience to take his revenge on others in the same coin, but still with a gradually increasing preference for good conduct and virtue, and a secret determination, when a favourable opportunity offers, and his fortune is made, of becoming in due course an honest man.

To this conception of an agreeable rogue, refined partly by good feeling, and partly by calculation, into a better being, Le Sage has imparted a wonderful air of particular, combined with general truth; for though *Gil Blas* is the representative of so wide a class, that almost all must acknowledge at times some common, and perhaps not very flattering features of resemblance between ourselves and him, he preserves throughout his whole career the most distinct individuality of character. Nor are the other subsidiary agents of the novel deficient in distinctness and clearness of portraiture. Sangrado, Scipio, the sleek Ambrose de Lamela, the eloquent but apoplectic archbishop, are made to stand before us. The historical personages have the same look of truth. Lerma and Olivarez, in particular, are admirably painted; so much so, that some Spanish critics, like De l'Isla and Llorente, have zealously maintained that Le Sage merely translated from some unknown Spanish manuscript which he had plundered. These critics reason, in fact, in such an ingenious way, as to make the accuracy or inaccuracy of Le Sage's Spanish pictures equally available for their argument. If he be perfectly correct in his portraits of manners, and his allusions to Spanish customs, that part of the work, they maintain, could not have been written by any but a Spaniard. If he falls into mistakes, it is equally clear that these apparent slips were introduced by him on purpose to hide the source of his depredations, and to confuse, like Cacus, the traces of his retreat. It is needless to say that the statement, at least as made in this unqualified form, is totally incorrect. Le Sage had no doubt thoroughly imbued himself with the spirit of the Spanish humour, as it appeared in Cervantes, and the writers of the Picaresco school; and, as already said, he borrowed liberally incidents from *various* Spanish romances; but he lent to the whole a point, gaiety, and philosophy, which presented the old materials with all the appearance of novelty, and the charm of an original invention. "All is easy and good-humoured, gay, light, and lively; even the cavern of the robbers is illuminated with a ray of that wit with which Le

Sage enlightens his whole narrative. It is a work which renders the reader pleased with himself and with mankind; where faults are placed before him in the light of follies rather than vices; and where misfortunes are so interwoven with the ludicrous, that we laugh in the very act of sympathizing with them. All is rendered diverting, both the crimes and the retribution which follows them."[1]

Though Le Sage rightly considered his characters as his chief object, he was well aware of the pleasing relief which might be given to his story by the judicious combination of the repose of landscape painting with the bustle of incident; and though he does not succeed in bringing before us, with the vividness of Cervantes, the sombre and parched plains or rugged mountain scenery of Spain, his work contains some country pictures, in a style of placid beauty, which are models of stillness, comfort, and serenity. To whom, for instance, does not that modest demesne at Lirias, watered by the Guadalaviar, with its mansion-house of four little pavilions, its garden bordered with orange trees, and ornamented with its basin of white marble, and the quaint, respectable, old Moorish furniture of the apartments, not to mention the olla podridas of Master Joachim, and the revenue of five hundred ducats a-year, rise up before the mind's eye, as the very ideal of that happy rural retreat which, to each of us, is to be the Euthanasia of a life of carefulness and toil; making us long for the time when we may be able to say with its fortunate possessor,

> "Inveni portum; spes et fortuna valete
> Sat me lusistis, ludite nunc alios."

Crebillon the younger.

It is unnecessary to dwell long on the romances of the younger Crebillon, (1707—1777), as to which the only circumstance which is remarkable is, that so much frivolity of manner, and real poverty of invention, could have obtained a temporary popularity even by the licence in which they indulged; yet that they were very popular for a time, we know; for Sterne represents his fille de chambre inquiring, at a circulating library, for the *Egarements du Cœur et de l'Esprit*, in 1768. French writers, however, appear to recognise in his pictures some resemblance to the society of the time; for D'Alembert says of him, "he draws with a delicate and just pencil the refinement, the shades, and the graces of our vices."

Diderot.

Much higher talent, though, like Crebillon's, stained by a shameful association with licentious and profligate pictures, appears in the romances of Diderot, (1713—1784). His talent as a narrator, in particular, was scarcely inferior to Voltaire's. He had the picturesque particularity of Richardson, with a more condensed expression. It is not, however, in his larger and more notorious romances, such as the *Religeuse*, that this talent is displayed. In these the tedium is as conspicuous as the indecency and impiety. It is in such short tales as *l'Histoire de Mademoiselle de la Chaux*, or *Les Deux Amis de la Bourgoyne*, short popular simple histories, contrasting strongly with that air of false simplicity, in reality tricked out with sentimental fard and tinsel, which Marmontel (1719—1798) has given to his amusing, but not very moral tales.

Marmontel.

Voltaire's romances.

The romances of Voltaire, (1694—1778), such as *Zadig*, the *Princess of Babylon*, *Babouk*, and *Candide*, have but slender pretensions to the title. They are chiefly satirical fictions, or illustrations, in the form of a tale, of irreligious or antisocial opinions. Their wit, their biting irony, their familiarity with the baser parts of human nature, their power of rendering trifles pleasing by the art of narration, are undeniable; but we must not look in them for probable incident, for Voltaire generally chooses, as if on purpose, some extravagant oriental groundwork as his canvass, and borrows from Ariosto, from Gulliver, from the Arabian Nights, or any source which suits his purpose;—nor for the delineation of natural characters, for both the incidents and personages are merely made the instruments for working out the preconceived theorem. They produce their effect, such as it is, not by their fidelity to nature, but by the ingenious malice with which its features are distorted.

From the time of Marivaux downwards, the tendency of the French novel had been to narrow the province of incident, and to extend proportionally that of sentiment. With Rousseau, (1712—1778), this tendency reaches its height. The description of feelings, and particularly of such as, though often experienced, are seldom expressed in words, was his peculiar field. Invention, either of character or incident, he has none. To paint one strong passion, to invest vice with an air of insane but reasoning morality,

> "To make madness beautiful, and cast
> O'er erring deeds and thoughts a heavenly hue
> Of words like sunbeams, dazzling as they past;"—

this is the main aim of his *Julie*, and the only one in which Rousseau has been at all successful. Even in this respect, too, the declamatory tone, the continued delirium of feeling, the total want of repose, which characterise the work, combined with the pedantry of its dissertations, become painful and oppressive. "Ce sont des amans," said Rousseau himself, speaking of his characters, "et non pas des academiciens." Never was an apology more misplaced. The real fault of *Julie* and *St. Preux* is, that they have both too much of the academician in their composition, and too little of the lover, so far as the expression of natural passion in simple words is concerned. We have never been able, in reading the romance, to persuade ourselves that its real eloquence was not as dubious as its morality. It is not easy, indeed, in perusing Rousseau's apostrophes to purity and virtue, to avoid thinking of the strange commentary which his practice furnished to his theory. It was said of Sterne with severity, but perhaps with some justice, that he could bestow upon a dead ass the pity which he denied to a living mother. And the man of nature and of truth, who expends his trembling sensibilities on paper, suffers a fellow-servant to be punished for the theft he had himself committed, and provides for his natural children in the foundling hospital.

The total corruption of an exhausted society, tottering to its fall, with the external varnish of gaiety and wit by which it tried to gild its decay, are aptly represented in the licentious romances of Louvet and La Clos; its still more vulgar profligacy in the coarse and incoherent, but occasionally striking and original novels of Restif de la Bretonne, (1734—1806). The works of the two former writers are unfortunately but too well known; the numerous and hasty productions of the eccentric printer, who was accustomed often to set up his strange compositions in type, without a manuscript, as the ideas occurred to him, are now almost completly forgotten. Yet Schiller and several eminent German critics, have spoken with high approbation of the vigour and talent which they evince in some parts, however defective or revolting in others. "I have scarcely *imagined* any thing," says Restif, in his *Drame de la Vie*; "I have simply related; my life has been so full of events, that I have made four-and-twenty volumes out of it." Any one, indeed, who writes, as Laharpe says of Restif in his *Correspondence Russe*, under the persuasion, that all that he had seen, and thought, or learnt, deserved to be printed, and who acted faithfully on that principle, could hardly fail to produce compositions with very nearly the merits and demerits of the novels of Restif; that is to say, with the coarseness of feeling which was natural to the man, with the disjointed air which a set of unconnected incidents from life must present, and yet with that degree of freshness and truthfulness of painting, which sketches from life almost invariably possess, however humble or disagreeable may be the department from which they are drawn. His best novel is usually considered to be the *Paysan Perverti*, which appeared in 1776.

---

[1] Sir Walter Scott's *Lives of the Novelists*—Le Sage.

Two writers may be pointed out, however, about this period, who were the representatives of a better taste and better feelings.

. Pierre. Bernardin de St. Pierre (1737—1814) may be regarded as the connecting link between the eighteenth and the nineteenth century: a graft of Fenelon upon Rousseau. His pathos no doubt often merges in a weakly sentimentalism; but the calm idyllic beauty of the *Paul and Virginia* and the *Indian Cottage* (1789—1792) was not without its use in restoring to French literature a feeling for nature and its simple enjoyments, and the acknowledgment of a Providence, a belief which both philosophy and fiction had for some time past been labouring to obliterate.

The defects of St. Pierre, with very little of his redeeming excellencies, appear in the *Atala*, *Rene*, and *Natchez* of Chateaubriand. He is, no doubt, in some departments an original thinker, and a man of a poetical imagination, though a degree of vagueness and mysticism mingles even with the best of his works; but as a novelist, his sickly sentiment and exaggeration of feeling are fatal to his success.

When the limbo of the Revolution, after its billowy heaving, began to settle again into something like a calm, under the despotism of the Consulate, the novel took the direction of broad and extravagant humour, derived from the gaieties and vulgarities of middle life, and, as might naturally be expected, liberally sprinkled with indecency, in the voluminous novels of Pigault Le Brun,—to whom it would be unfair to deny considerable powers of broad mirth, and a fertility in imaginary burlesque situations, which remind us of Smollett. But the questionable character of the novel-writing of this period is not universal. In the tales of Madame Cottin, the authoress of *Elizabeth* and *Mathilde*, a pure morality, and feminine tenderness, reappear; and though those of Madame de Staël, with all their eloquence, occasionally inculcate more doubtful lessons, her genuine admiration for pure and elevated feeling, prevents her from willingly lending her talents to the palliation of vice. The novels of Madame de Staël, however, are far more German in their character than French.

dier. The works of the literary veteran, Nodier, certainly owe their attractions more to the charms of a beautiful style than to their substance. Throughout his whole course he has been but an imitator, putting on successively the manner of other writers. The *Werther* of Goethe appears to have first given the tone to his novels, and the passionate energy and wild complaints of the German suicide were reproduced in his tale of *Therese Aubert*. To the influence of Goethe succeeded that of Byron, and the spirit of the *Corsair* and *Lara* were infused into the Bandit *Jean Sbogar*. From Byron he passed to Scott, whom he has imitated in his *Trilby, ou le lutin d'Argail*, a production, the effect of which, though meant to be serious and pathetic, is unintentionally of the most comic kind, for the "tricksy spirit" of Argyle in the hands of Nodier becomes one of the most absurd of supernatural conceptions. In his *Smarra* again, a Thessalian story in the manner of the sorceries and diableries in the Golden Ass of Apuleius, he seems to have been influenced by the German night pieces of the school of Hoffmann; and he certainly succeeds almost as well as his German master, in producing a strange ephialtic effect by a cloud of misty murky phantoms, which pass before us as if in a feverish and uneasy dream.

With the restoration of the Bourbons, some degree of external decency, at least, distinguished the productions of the French press, though still the license which its novelists permitted to themselves in their comic works, and the extravagant and terrible cast of their more tragic stories, indicated at once a looseness of morality, and a coarseness of taste, which might, in some measure, have prepared the world for that strange and revolting spectacle which the literature of fiction has presented in France, since the Revolution of 1830. The manner of Pigault le Brun, was imitated and improved upon by Paul de Koch; for, adopting his principle of drawing chiefly from middle life, and his love for the representation of comic mischances, he has thrown into the best of his novels, scenes of simple humour, of tenderness, and even of powerful passion, to which the novelist of the Revolution had made no pretensions. To sneer at him as a Parisian cockney, or as the romance writer of the Grisettes, is easy; but we are much mistaken if his tales, homely and even coarse as they may be, will not be read when the atrocities of Sue and Masson, and the delicate depravities of Balzac, are forgotten.

Victor Hugo. In the higher sphere of romance, we have, during the same period, the earlier productions of Victor Hugo, *Hans of Iceland*, and *Bug Jargal*. *Hans of Iceland*, wild and extravagant as it is, is evidently not the work of an ordinary writer. A stern, savage northern spirit is breathed into the romance. Spiagudry, Orugix, even the monster from whom the tale derives its name, strange and ghastly creations as they are, exercise a certain fascination over the mind; and the youthful poet has turned to great account the dreary wilds, gloomy lakes, stormy seas, and ruined fortresses of Scandinavia. *Bug Jargal* was decidedly inferior to *Hans of Iceland*. The essential improbability in the character of a negro passionately in love with a white woman, and yet tempering the wildest passion with the deepest respect, is obvious; nor is that improbability disguised by the art with which Hugo has framed his story. There was more of genius, we think, in his *Dernier Jour d'un Condamné*, in which Hugo, like Sterne, has taken a single captive, shut him up in his dungeon, and then "looked through the twilight of the grated door to take his picture." In this little work he has shown how a profound interest might be given to a mere register of sensations, and a dramatic movement imparted to a monologue, in which the scene shifts only from the Bicètre to the Conciergerie, the Hotel de Ville, and the Place de Grève. Hugo's great novel, *Notre Dame de Paris*, appeared in 1831. It is needless to speak of a work which has been more than once translated into English; and the characteristics of which, the mingled genius and extravagance, the poetical spirit in which it is conceived, and the want of nature in the characters which it pourtrays, resembling distorted and hideous masques rather than men, are now very generally and correctly appreciated.

The popularity of the romances of Scott led about the same time to a multitude of imitations, by Jacob and others, of which the *Cinq Mars* of Alfred de Vigny appears to be generally considered the most successful.

We have no idea of entering on that mass of revolting performances, equally offensive to good morals and good taste, with which the French press has teemed since 1830; and which we are but too happy to consider, with the French themselves, as a literature of transition. This school of blood and voluptuousness, funereal horrors and drunken orgies, the transitions in which remind one of the stage arrangement in the rehearsal,—"the coffin opens, and a banquet is discovered,"—we feel assured, can be of no long duration; and already we believe, that the French public begin to feel that they have had enough of the endless Balzac, and Janin, and Sue, and Soulie, and Masson, and the other labourers in this Montfaucon of fiction. As for Madame du Devant, or George Sand,—the Chevalier d'Eon of French literature,—a being whose sex it would be impossible to ascertain from her works, with the warm passions and headlong eloquence of the woman, and the audacious speculation of the man;—while the principles which she labours to inculcate, are of the most odious nature; and the cynical hardihood with which she paints scenes from which any woman would turn aside, is perhaps the very worst proof which French literature at present presents of a degraded standard of delicacy and right feeling among the female sex, we cannot deny that she appears to us to possess far greater talent, even genius, though misdirected, than any of the other ephemeral novelists to which we have alluded. In particular, she has an imagination singularly alive to natural beauty; her pictures of scenery are frequently captivating; and one evening landscape of Venice, in her *Dernier Aldini*, has the combined charm of deep sensibility and truth. By far the most pleasing of her novels, because it in a great measure keeps in the background her peculiar opinions, is *André*. And yet even the general purity and right feeling of the tale is marred and interrupted by some passages which English readers at least would wish to blot.

German novels and romances.

The field of the novel or romance is not that which has been cultivated in Germany with the most success. The labourers indeed have been many, the produce most abundant, but the quality of the harvest is at best equivocal. Down to the time of Goethe and Tieck, the German literature of fiction was almost entirely imitative, deriving both its form and spirit from other nations. Since their time, if it presents a greater air of originality, it has generally assumed a character so fantastic, so unreal, so unlike all that we have been accustomed to associate with the idea of a novel, that it is extremely difficult to comprehend what is really the conception of the word entertained in Germany.

As we have no very high idea of the German prose fictions, the space which we propose to devote to them will be extremely limited; for we shall confine ourselves to a mere indication of the successive phases which the German romance has presented. In doing so, it seems unnecessary to go back beyond the latter portion of the eighteenth century, or to revive the names of works and authors which even the Germans themselves have forgotten. The earlier part of the eighteenth century had been occupied with numerous imitations of the *Robinson Crusoe* of Defoe, or of the family pictures of Richardson, the merits of which are not of a nature to demand notice in the present sketch.

Wieland.

In the Greek romances of Wieland, (1763—1812), such as the *Agathon*, the *Aristippus*, *Peregrinus Proteus*, and *Agathadämon*, the same didactic tendency is observable which distinguishes those of Voltaire, but without their cynyical and mocking tone, and with a much greater power, if not of actually inventing character, at least of working up the scanty materials furnished by history into a consistent and plausible portrait of the historical personages of antiquity; as in his *Socrates*, and still more perhaps in his *Aristippus*. The main fault of his novels, besides this didactic tone, which pervades them all, is the frequent repetitions which they contain of the same views and personages. *Agathon* in one manner, and the *Abderites* in the other, contain the germ of almost all Wieland's other writings. The sceptical Hippias, for instance, only puts off the Athenian stole in Agathon, to assume the mantle of the Calendar; the Danæ of that novel revives again in Theoclea and Devidassi; the youth of Athagon, in Delphi, is the prototype of that of Peregrinus in Parium; and many such instances must occur to any one familiar with Wieland. He is a mannerist, in short, as to his matter, and the mannerism extends even to his style, which, though flowing and facile, has not a little of the solemn loquacity of Boccaccio. This diffuseness is less felt in his shorter tales, where his philosophy is not so obtrusively displayed; and for this reason we prefer his *Don Sylvio de Rosalva*,—the history of a quixotic believer in fairyism, gradually converted to common sense by the extravagant demands which are made upon his belief, assisted by the charms of a mortal beauty,—and his little romance of the *Salamander and the Statue*, to his more elaborate and aspiring compositions.

The influence of the novels of Richardson and of Fielding reappears about this time in a liberal effusion of family novels, some pourtraying the serious and sentimental, others the comic aspect of domestic life. Among the sentimental novelists, Augustus La Fontaine (1758—1831) may be considered as the most successful, and undoubtedly the most popular. He painted life as he had seen it in the little German towns, villages, and chateaux of respectable proprietors about him, or as he had witnessed it during his campaigns as army chaplain, without ornament or alteration, without any pretension to imagination; and though there is at times something vulgar and tawdry in his sentimentalism, there is also a great deal of quiet simple nature in such scenes of common life and domestic happiness as he has exhibited in his family of Haller; and a tone of frankness and good humour, which carries the reader pleasingly along through incidents and characters that in themselves are common-place enough.

La Fo taine.

The comedy of family life found numerous representatives, of whom Wetzel, Müller, Schulz, and Hippel, attracted some notice in their day and generation. Even yet the *Siegfried von Lindenberg* of Müller, which appeared about 1779, and of which many editions have appeared, may be admitted to be a natural and amusing performance.

Comic mances.

A union of the sentimental with the comic in these domestic pictures was attempted at a somewhat later date in the very singular novels of Richter, (1763—1825), a man of high powers, which he knew not how to use, and which were alloyed in no common degree by false taste, and an incurable affectation of singularity. His earliest novel, the *Grönländische Processe*, appeared in 1784. The tricks and claptraps to which Sterne occasionally descends, we find habitual with Richter. The very titles of some of his works, such as *Selections from the Papers of the Devil, or Recreations under the Cranium of a Giantess*, and the absurd devices by which he generally introduces his narration, as in the *Hesperus*, where a series of letters is represented as mysteriously conveyed to the author in letter-bags tied round the neck of a shock-dog, betray a mind anxious to astonish by fantastic conceits, and insensible to the beauty of simplicity. The constant recurrence of these instances of literary quackery, the want of connexion which his chaotic narrations exhibit, combined with the visionary cast of his views, justifying his own remark, that the empire of the Germans was peculiarly that of the air, has been fatal, and we think justly, to all attempts to naturalize Richter in this country. His pathos we think in the worst style of false, and often meaningless, effusions of sentimentality; but as a quiet humourist, blending good feeling with his satire, he is often very successful. In this respect we admit the truth of the observations of Mr. Carlyle, from whose estimate of Richter's genius we in other respects fundamentally differ: "It is on the strength of this, and its accompanying endowments, that his main success as an artist depends. His favourite characters have always a dash of the ridiculous in their circumstances, in their composition, perhaps in both. They are often men of no account, vain, poor, ignorant, feeble; and we scarcely know how it is that we love them; for the author all along has been laughing no less heartily than we at their ineptitudes. Yet so it is; his Fibel, his Fixlein, his Siebenkäs, even his Schmelzle, insinuate themselves into our affections; and their ultimate place is closer to our hearts than that of many more splendid heroes. This is the test of true humour; no wit, no sarcasm, no knowledge, will suffice; not talent, but genius, will accomplish the result."

Richter.

Feudal mances

A strong contrast to these pictures of ordinary life, whether serious or comic, was presented by the mass of romances connected with the feudal periods in Germany, which appeared from about 1780 to 1800, and formed the counterpart of the Ritter-stücken or chivalrous dramas, with which the stage had been inundated since the example had been set by Goethe's *Goetz of Berlichingen* and Babo's *Otho of Wittelsbach*. Cramer, Spiess, Schlenkert, and Veit Weber, (Leonhard Wächter), were the favourite writers of this turbulent school of fiction, which in all probability took its rise from the popularity of the romances of Mrs. Radcliffe. Their materials were the blood-stained period of Faustrecht and Vehm-Gerichte, feudal tyrants, suffering damsels, devoted knights, with abundance of single combats and splintering of lances, raising of trap-doors, escapes by sliding pannels, imprisonments in bottomless dungeons, murders, witchcraft, and apparitions; in short, all that apparatus of the terrible, which, even in such hands, has a certain fascination for the boy, but awakens only a feeling of the ridiculous in the man.

Another department of German fictions likewise dealing with the marvellous, but fortunately cultivated by writers of a very different order of talent, was the Mährchen, or legendary tale. Three different modes may be pointed out in which this class of subjects has been treated.

Musæus.

The first is exemplified in the *Volksmärchen*, or popular tales of Musæus, in which the groundwork of marvellous tradition which the writer has selected is treated, not in the spirit of belief, but of a laughing scepticism, and where the writer relies for effect, not so much upon the interest of his materials, as upon the wit, the satirical allusions, and the quaint description or broad drollery which he is able to infuse into the original legend. Whatever in such traditions bordered upon awe or terror, Musæus rejected; he viewed even these creations of the fancy in a prosaic light, and selected only such features as could be wrought into his ingenious mosaic of fanciful marvel, picturesque description, and sly and somewhat irreligious pleasantry, in the style of Voltaire. What he attempted, however, he accomplished with success. Some of his tales, such as *Stumme Liebe*, (Dumb Love), and *Melechsala*, might be cited as models of the art of combining the childish interest of a nursery tale with that shew of irony or philosophy which affords even to grave personages an apology for the perusal of popular tales.

Tieck.

In this semi-derisive style of treating the traditionary legends of his country, Musæus remains the solitary writer of talent. This natural tendency of the German mind towards earnestness and belief, even in the case of the marvellous, led to a very decided preference of the serious manner in the treatment of such themes. And undoubtedly at the head of this second mode of treating the legend stands Ludwick Tieck, (born 1773). Questionable as we think his claims are to the highest distinction, either as a poet or a novelist, in the proper sense of the term, his success in the management of traditional marvels in a poetical spirit is undeniable. He seems without an effort to throw himself back into the spirit of primitive and superstitious periods, when the agency of an invisible world formed an article of belief, and exercised the strongest influence over the conduct of life; a time of supposed prodigies, and omens, and secret charms, whose agency pervaded and controlled the course of nature. In reading the best of these legends of Tieck, such as *The Fair Eckbert*, *The Love Charm*, or *Peter of Abano*, we feel that he has the power of carrying us back in advanced age into the very realm of Fairyland, and subjecting us anew to the influences of childhood. "These legends have a freshness about them like that of the earliest morning, a sweetness as of wild flowers, and a calm beauty, caught as it were from a radiant sunset or a rising morn. The reader of the *Runenberg* is brought face to face with the presiding spirits of the animal and vegetable kingdoms; now he feels as if he were embosomed in luxurious vegetation, bathed in fertilizing dew, and fanned by balmy zephyrs, and now as if he were transported to cavern depths or darkest mines, where mountain spirits exercise an unholy influence. All the other legends, *The Fair Eckbert*, *The Fairies*, and *The Trusty Eckhart*, have the same beauty and significance; but it is impossible by mere description to give any idea of their peculiar nature. They must be studied and felt to be at all understood."[1]

We are here speaking of Tieck merely as the writer who has treated the traditional tale in the most poetical spirit. Within the domain of the novel, taking the term even in a very extensive sense, our estimate of his powers will be very different.

The mode of treating the legendary lore of Germany, of which the tales of Tieck had furnished the first example, as the most agreeable to the national character, soon found numerous, or, it might rather be said, numberless imitators. For the last thirty years, the example of Tieck has been implicitly followed, and all the legendary novelists of Germany have been melancholy and gentlemanlike, after the pattern of the Phantasus. Of these the writers best known to English readers, through translation, are the Baron de la Motte Fouque, the author of *Undine*, the *Magic Ring*, and *Sintram*; Chamisso, the author of *Peter Schlemihl*; and Apel, the author of the *Freyschütz*. It may be doubted whether better specimens of the German tale might not be selected from writers with which the English public is not familiar,—some of Henrich Steffens' short legendary stories in particular,—such as, the *Sleeping Bride*, (Die Schlafende Braut) and the *Nightly Betrothal in the Church of Rörwig*, (Die Nächtliche trauung im Kirche Rörwig), which have not yet found a translator, appear not undeserving of the attention of the lovers of the marvellous. In the wild productions of Achim von Arnim, such as the *Countess Dolores*, and *Isabella of Egypt*, traits of talent sparkle in the midst of absurdity. And from the works of Clemens Brentano, and of Zhokke, the author of *Abelino*, several interesting legends might be selected. In particular, we are surprised that the simple and beautiful legendary tale by the former, "The History of the Brave Kasperl and the Fair Annerl," is yet untranslated.

Hoffmann.

The third form in which the Mährchen was employed, but, at the same time, perverted from its proper purpose, and subjected to a more Mezentian union than it had submitted to even under the satirical despotism of Musæus, was in the fantastic or grotesquely terrible manner introduced by Hoffmann, and, since his death, so injudiciously and unsuccessfully imitated both in Germany and in France. Hoffmann's manner cannot be considered as entirely original, since an approach to it may be pointed out in the *Diable Amoureux* of Cazotte. It is singular, however, that his productions, such as the *Sandman*, the *Magnetizer*, the *Devil's Elixir*, and others of that class, deriving their whole interest and effect from their connexion with the peculiar nature and idiosyncrasy of the writer's mind, and so incapable of being imitated with the least success by any one not possessing the same anomalous mental conformation and physical irritability with the Prussian judge, should have exercised a very decided though temporary influence over the literature, not merely of Germany, but of Europe; and it proves that, notwithstanding the extravagances, there does reside in them some charm,—something which appeals successfully, not, indeed, to the mind in its calmer mood, but to the imagination when in a state of temporary excitement. Only in such a mind as Hoffmann's, moulded into its existing shape by an ill-omened union of influences, mental and bodily, habitually haunted with gorgons and presentiments, seeing traces, as it were, of the devil's hoof in the commonest paths of life, and starting and trembling at the chimæras with which his imagination peopled solitudes—could the phantoms bred in his eccentric brain, and nurtured amidst the fumes of a Berlin tavern, have ever assumed that appearance of reality and belief which could render their introduction into a work of fiction at all practicable. Only by a mind accustomed, from a painful experience, to brood over and dissect the origin and connexion of these strange phenomena, half mental half physical, which make "life a dream," but with a nightmare accompaniment, could the possible connexion of this phantasmagoria with real existence, in morbid minds, be rendered so far intelligible as to redeem them from the charge of the merest puerility. Hoffmann's tales, though they constantly suggest the idea that they have had their source in the inspiration of opium, seem really to be the only compositions in this style of grotesque horror, which can be said to possess the redeeming quality of genius. They remind us of the images of our dreams, calling up before us, as in sleep, long perspectives of gloomy vastness, broken here and there by the light of the strangest ignes fatui, along which are seen, flitting in antic movements, bands of the strangest creatures, such as those which, in the pictures of Teniers, disturb the solitude of St. Anthony, or which give a strange blending of the humorous and the horrible to the distempered sketches of Callot. Yet, as a proof that the talent of Hoffmann was by no means confined merely to the fantastic and the supernatural, we may notice his truthful and vigorous picture of the German burgher life of the middle ages, in his *Master Martin and his Apprentices*, and his *Mademoiselle de Scudery*, a tale of vivid and fascinating interest, founded on a historical groundwork, moving in the simplest and most direct manner towards its object, and exciting the feeling of curiosity and suspense even to the last.

---

[1] *Germany*, by Bisset Hawkins, p. 126.

Heinse.

Some notoriety of an evil kind was obtained by a class of novels, in which the attempt was made to invest sensuality with the graces of art, or to merge art in sensuality. Such were the *Ardinghello* of Heinse (1749—1803), in which painting was made the apology for the introduction of voluptuous pictures, and his *Hildegard von Hohenthal*, in which music was made to minister to a similar purpose,—no unfit sequel to a literary life which commenced with a translation of Petronius. In truth, in the whole range of the German novels, the tendency to an undue license of this kind is observable. In those of Goethe, though veiled by an appearance of decency, it is sufficiently perceptible; nor does Tieck appear free from the common taint. Many passages in *Wilhelm Meister* are highly objectionable; and such a novel as the *Wahlverwandschaften* we regard as untranslateable into English.

Goethe.

Of Goethe's novels we have already expressed our opinion in our biographical article on Goethe himself. If the merits of a novel consisted, not in exhibiting an epitome of human life, more or less poetically conceived, according to the prosaic or imaginative turn of the writer's mind, but in speculating ingeniously on painting, agriculture, landscape, gardening, the rules of good composition, or the state of the theatre, connecting these speculations by a thread of mystical narrative, and introducing us to a set of beings without the least trace of reality about them, who all appear to be playing some theatrical part in a dreamy representation of life, which seems to have no intelligible object,—Goethe may be a great novelist. With an English public, demanding some firm basis of reality, instead of that unsubstantial cloud-land which envelopes us in the *Wilhelm Meister's Lehrjahre* and *Wanderjahre*, and accustomed to insist on a plain meaning as a preliminary to poetical embellishment, he never can be a favourite. A novel which does not explain its purpose without a commentary, seems to violate the essential laws of such compositions; but a novel, in regard to the object of which no two commentators agree, is an anomaly in literature. Most of the German critics, indeed, though professing a great admiration of these singular performances of Goethe, are careful to confine their observations, in regard to the meaning or object of the novels, to the merest generalities. They describe *Wilhelm Meister*, to use the congenial language of an English admirer, as a picture "of warm, hearty, sunny, human endeavour, a free recognition of life in its depth, variety, and majesty, *but as yet no divinity recognised there*." The latter portion of the sentence is intelligible, and is unfortunately true, but the rest reminds us of Mr. Dangle's remark, that the interpreter appears the harder to be understood of the two.

Tieck.

These observations apply, with slight modification, to the novels of Tieck, when he abandons the province of the traditional tale, and attempts subjects connected with real life; the characters, the incidents, the whole cast of the tale, appear so extravagant, that, but for the grave and laudatory criticism with which these effusions seem invariably to be received by his countrymen, it would be difficult to believe the author serious. His first romance, *William Lovel*, was a gloomy and revolting extravagance, and his later caprices, such as *Das Alte Buch*, (the Old Book), the *Vogelscheuche*, (Scarecrow), *Eigensinn und Laune*, (Self-will and Humour), *Wunderlichkeiten*, (Marvels), are utterly unworthy of a man of genius. Even the merits of his *Dichterleben*, (a Poet's Life), have been greatly exaggerated. Any tale, in which Marlowe and Shakespeare figure as actors, has a certain interest for a Briton; but beyond some eloquent disputations on the drama, and the formation of a poet's mind, in which Shakespeare and his companions are made to utter modern German theories, the most opposite to English notions of the sixteenth century, we cannot perceive wherein the peculiar merit of this much-lauded performance lies. Tieck has said absurdly and presumptuously of Sir Walter Scott, that "it is surprising how little he wants to be a poet, but how much that little outweighs all that he is." Let any one who has read Tieck's *Aufruhr in den Cevennen*, in which he has come in competition with the Scotch novelist on an historical subject, judge whether he has himself made a nearer approximation to that character.

The talent displayed by Schiller in his *Verbrecher aus Ehre*, and his fine fragment of the *Armenian, or the Ghost Seer*, excites regret that he did not give us less of philosophy, and more of fiction. It is an unfinished tale of mystery, of deep interest, the idea of which, it is supposed, was suggested by the juggleries of Cagliostro, and in which Schiller, though he never witnessed the scenery which he describes, has caught the spirit of silence and secrecy which seems to pervade Venice, with the same success as, in his *William Tell*, he has transported us into the mountain recesses of the Oberland. And Lord Byron has recorded the strong impression made upon his mind by the recollection of the incomprehensible Armenian, one of those conceptions which he was accustomed by anticipation to associate with the image of the city of the sea.

Schiller.

Several female novelists, too, have respectably supported the pretensions of their sex; such as Fanny Tarnow, the Baroness de la Motte Fouque, Johanna Schopenhauer, Henrietta Hanke, and Caroline Pichler, the able authoress of *Agathocles*. Many of their productions exhibit talent, grace, and facility of style, but we should be at a loss to name any for which the praise of genius could justly be claimed.

The class of romances called *Kriminal Geschichten*, turning on stories of secret guilt discovered by circumstantial evidence, has been a numerous one in Germany. At the head of this class of novelists stands Kruse, who certainly possesses in a high degree a power, which at the present day appears to be rather a rare one,—that of constructing an ingenious and complicated plot, keeping the curiosity constantly on the stretch, and defying conjecture as to the result, till the author himself chooses to furnish the solution. The *Ring, Oath and Conscience, Diodatis' Birth,* the *Dance of Death,* and the *Red Dragon,* are masterpieces in this style of invention, which, though of a sufficiently prosaic character, yet possesses, at least, this cardinal merit, that it is rarely tedious.

Historical romances have always been numerous in Germany; and after the appearance of those of Sir Walter Scott, they became still more so. Some of the chivalrous pictures of Tromlitz, Van de Velde, and Blumenhagen in this style are spirited, but in general the historical romance of Germany does not rise above mediocrity. "Sunt bona, sunt quædam mediocria, *sunt mala plura.*" Let us except the very remarkable tale of *Michael Kohlhaas,* by the unfortunate dramatist Kleist, (1776—1811). In all of Kleist's tales there is too much of a spectral and fatalistic character; he delighted to contemplate and to delineate life as necessitated by a mysterious and iron destiny. *Kohlhaas* is not entirely free from a tinge of the supernatural, which harmonizes ill with the deep, humble, human interest of the tale itself; and no where does the idea of a grim and unrelenting fate appear in more saddening colours. There is truth, therefore, in Goethe's remark as to this romance, that "it brings prominently into view a dissonant principle in nature, with which poetry ought not to meddle, with which it cannot reconcile itself, let the handling of the matter be never so exquisite." And yet this vigorous and truthful picture from the Lutheran times, must be to English readers an object of interest, from the contrast it exhibits to the usual style of the German novel; for it is told with a directness, a simplicity, a dramatic liveliness, and an absence of unnecessary reflection, which are qualities of rare occurrence beyond the Rhine.

(W.W.W.W.)

ROMAGNA, a province of Italy, in the pope's territories, bounded on the north by the Ferrarese, on the south by Tuscany and the duchy of Urbino, on the east by the gulf of Venice, and on the west by the Bolognese and a part of Tuscany. It is fertile in corn, wine, oil, fine fruits, and pastures. It has also mines, mineral waters, and salt-works, which make its principal revenue. Ravenna is the capital town.

ROMANIA or RUMELIA, an extensive province of the Turkish empire in Europe, called by the Turks the Ejelat Rumili, or the land of the Romans. In the more extended sense it comprehends the whole countries to the west and the north of the Bosphorus, but in a more peculiar sense it included the ancient Thrace, Bulgaria, Servia, and Greece, except a strip on the coast and the islands which are in the Pashalic of the Capudan Pascha, and one distinguished as the Ejalet Dscheseir. It is divided into 24 districts or sandgiacets, extends over 105,182 square miles, and probably contains 6,000,000 inhabitants. The capital of it, as of the empire, is Constantinople or Istambol.

ROMANO, GIULIO, a famous painter of the Roman school, was born at Rome in 1492. He was the favourite pupil of Raphael, who had such an affection for him, that he appointed him, with John Francis Penni, his heir. He first signalised himself by his Battle of Constantine, which he painted from a design of Raphael's, and which was particularly admired by Poussin.

When he had completed the hall of Constantine in the Vatican, from Raphael's designs, he went to Mantua, where the patronage of the Gonzaghi family excited him to those great works, and those magnificent plans by which Mantua and the palace Del T. have been so highly decorated. In the decorations of this palace, Julio prepared the cartoons, and had the pictures executed by his pupils; but he afterwards corrected and finished them. Modern pencils are said to have covered the touches of Julio, especially in the Fable of Psyche, the Allegories of Human Life, and the Giants Storming Heaven, where his composition and design are alone seen. In the fresco paintings of the old palace or corte of Mantua, which refer principally to the histories of the Trojan war, his peculiar merits are better perceived. Helen Asleep, Vulcan forging arms for Achilles, are considered beautiful, and Minerva slaying Ajax is regarded as sublime.

The most remarkable of the altar pieces of our artist are the three frescoes of St. Marco; and in the church of St. Christofero, the athletic figure of that saint supporting the infant Jesus. His Martyrdom of St. Stephen on the head altar of the church of St. Stephen at Genoa, is preferred to them all.

His conceptions were more extraordinary and more elevated than even those of his master, but not so natural. He was wonderful in the choice of attitudes; but did not perfectly understand the lights and shades, and is frequently harsh and ungraceful. The folds of his draperies, says Du Fresnoy, are neither beautiful nor great, easy nor natural, but all extravagant, like the fantastical habits of comedians. He was, however, superior to most painters, by his profound knowledge of antiquity; and, by conversing with the works of the most excellent poets, particularly Homer, he made himself master of the qualifications necessarily required in a great designer. Julio Romano was also well skilled in architecture. He was employed by Cardinal de Medicis, who was afterwards pope under the name of Clement VII.; he ultimately settled in Mantua, whither he was invited by Frederick Gonzago, marquis of that city, in order to avoid his being justly punished for having drawn at Rome the designs of twenty obscene plates, engraved by Mark Anthony, to which Aretine added the same number of sonnets. Julio Romano embellished the city of Mantua with many of his performances, both in painting and architecture, and died in that city in 1546, at 54 years of age.

ROMANS, a city of France, in the department of the Drome, and the arrondisement of Valence, situated on the right bank of the Isere. It has considerable manufactories of stockings, caps, hats, and silk goods, and makes large quantities of oil from wallnuts. The fruit, especially melons, is chiefly sent to Grenoble. It contained in 1836, 9285 inhabitants. Lat. 45. 6. Long. 4. 57. E.

ROMBLON or ROMBLINO, one of the smaller Philippine islands, about 30 miles in circumference. Long. 121. 58. E. Lat. 12. 40. N.

ROMAN HISTORY.

Rome, a city of Italy, formerly the capital of the greatest empire in the world, and still remarkable as the chief seat of the papal power, is situated on the river Tiber, in east long. 13°, and north lat. 41° 45′.

To trace, even briefly, the rise and progress of this mighty city towards universal empire, would demand a voluminous history, especially were we to enter into disquisitions respecting the views which have been adopted in this article; but as our limits forbid such an attempt, we must content ourselves in a great measure with the statement of general results, with such occasional references as may enable our readers to investigate the subject at greater length; and we think it fortunate, that many of the views which were held as mere paradoxes when first proposed by Niebuhr, may now be regarded as firmly established, and without hesitation followed as essentially correct.

For the history of the various tribes, which, when united under the Roman name, formed one mighty nation, we must refer to the different heads under which, in other parts of this work, they are mentioned. The chief of these were the Oscan, probably the most ancient race that inhabited Italy; the Pelasgian, under which designation may also be comprised the Tyrrhenian,[1] with its numerous branches; and the Etrurian, which was marked by various features distinguishing it from both the other races, being also probably less ancient than either. From all that appears in history or tradition, the Oscan, Opican, Auruncan, and Ausonian, were the same race of people, and the earliest inhabitants of that part of Italy contained between Oenotria and Tyrrhenia, or the country of the Etruscans;[2] in a word, they were the original stock whence sprung several of the most powerful nations of Italy, as the Sabines or Sabellians, the Samnites, and others. The Pelasgi[3] appear to have been a branch of that once mighty race of whom traces may be discovered from the river Strymon, along the coast of Ionia, throughout Greece and its islands, and along the maritime shores of Italy. It was from their Pelasgic ancestors that the Romans derived the radical affinities which are found to connect the Italian language with that of Greece, both having had, at some remote period, a common origin. The Pelasgi seem to have driven the Oscan nations from the sea-coast, back to the mountains, and in their turn to have been overpowered in part of their acquired territory by the Etruscans. The origin of this latter people is involved in obscurity hitherto impenetrable.[4] They display many traces of an oriental, or, as some think, of an Egyptian origin. We incline, for many reasons, to believe them of Phœnician extraction; not merely the peculiarities of their alphabet, but those also of their religious rites, bearing a very close resemblance to the most ancient forms of the Phœnician language and religion. It is probable that a careful investigation into the customs, laws, and religion of the ancient Etrusci, or rather Raseni, to use their own name, will ultimately prove them to have belonged to a race more ancient still than even the Phœnicians, that is, to the ancient oriental race whence the Phœnicians themselves derived their origin, their language, and religion.

Respecting the institutions of these primitive races, very little is known; yet from that little, important conclusions may fairly be drawn. Both the Osci and the Pelasgi seem to have lived under the patriarchal form of government; the origin of which is to be traced to the paternal sway which a father naturally exercises over his household, and the head of a tribe, or number of households, over the whole collectively. The Etrusci, on the other hand, appear to have adopted the system of *castes*, and especially to have been very much under the influence of a sacerdotal caste, which was of course hereditary, and which possessed almost unbounded influence over the rest of the nation. The effect of the combination of these nations, and their peculiar institutions, in forming the character of the Roman people, will soon appear.

Founda
of Rom
B.C. 7

Rome itself is said to have been founded in the year 753 B.C. This date, therefore, we shall assume as the most probable, if not absolutely authentic, and shall make it the basis of all subsequent chronological statements.[5] According to the fabulous accounts preserved by Livy, the founders and earliest inhabitants of Rome were of Trojan descent. Æneas is said to have led a colony of Trojans, after the destruction of Troy, through a series of perilous voyages and adventures, to the shores of Italy, near the mouth of the Tiber. Here he formed an alliance with Latinus, king of the adjoining country, received his daughter Lavinia in marriage, and built a town, called, from her name, Lavinium. A war, which soon afterwards arose between the new settlers and the Rutulians, terminated in the death of their king, Turnus, who was slain in battle by Æneas. Another war ensued between the Trojans and Mezentius, king of the Etruscans of Caere. In this war Æneas himself perished, having been drowned in the Numicius, into which he was forced in a disastrous battle, and was succeeded by his son Ascanius, or Iulus. On the banks of the river where he disappeared, an altar was built in honour of him, and he was worshipped under the name of Jupiter Indiges. Mezentius soon afterwards fell by the hand of Ascanius, who thus obtained undisputed possession of the territory formerly held by Latinus. The Trojan settlers became completely incorporated with the people of the land, and from king Latinus they derived the common name of Latins. The thirty years had now elapsed during which it had been predicted that the Trojan race were to inhabit their first town, Lavinium. They removed to a more propitious situation, and built a new town on a lofty ridge farther inland, which overlooks all the land around it, and to their new abode they gave the name of Alba Longa. Of the Latian confederacy, this became the chief city; and hither the thirty confederate cities of Latium resorted to offer common sacrifices to the gods of the Pelasgic nation.

The traditionary legends proceed to state, that Lavinia, fearing some injustice from Ascanius, had sought shelter in the woods, where she gave birth to a son, named from that circumstance, and from his father, Æneas Sylvius. Ascanius, however, took no unfair advantage of his position, and was succeeded by Sylvius. For an uncertain period, the sceptre was swayed by successive monarchs of the Sylvian race and name, till the death of Procas. This king left two sons, Numitor and Amulius, but by birthright the throne belonged to Numitor. Amulius, however, seizing the government in defiance of his brother's right, caused Numitor's only son to be put to death, and made his daughter Silvia a vestal virgin, by which she became bound to perpetual celibacy. According to the legend, this scheme proved abortive; for Silvia became pregnant by the god Mars, and was delivered of twin sons. Amulius ordered the infants to be thrown into the river, and their mother to be buried alive; the doom of a vestal virgin who should violate her vow of chastity. The river happened at that time to have overflowed its banks, so that the two infants were not carried into the middle of the stream, but drifted along the margin, till the basket which contained them became entangled in the roots of a wild vine, at the foot of the Palatine hill. At this time a she-wolf coming down to the river to drink, suckled the infants, and carried them to her den among the thickets hard by. Here they were found by Faustulus, the king's herdsman, who took them home to his wife Laurentia, by whom they were carefully nursed, and named Romulus and Remus.

[1] See Niebuhr, vol. i. p. 38, *et seq.*

[2] Id. vol. i. p. 64, *et seq.*

[3] Id. vol. i. p. 29.

[4] Id. vol. i. p. 109, *et seq.*

[5] Id. vol. i. p. 262, *et seq.*

The two youths grew up, employed in the labours, the sports, and the perils of the pastoral occupation of their foster-father. But, like the two sons of Cymbeline, their royal blood could not be quite concealed. Their superior mein, courage, and abilities, soon acquired for them a decided superiority over their young compeers, and they became leaders of the youthful herdsman in their contests with robbers, or with rivals. Having quarrelled with the herdsmen of Numitor, whose flocks were accustomed to graze on the neighbouring hill Aventinus, Remus fell into an ambush, and was dragged before Numitor to be punished. While Numitor, struck with the noble bearing of the youth, and influenced by the secret stirrings of nature within him, was hesitating what punishment to inflict, Romulus, accompanied by Faustulus, hastened to the rescue of Remus. On their arrival at Alba, the secret of their origin was discovered, and a plan was speedily organized for the expulsion of Amulius, and the restoration of their grandfather Numitor to his throne. This was soon accomplished; but the twin brothers felt little disposition to remain in a subordinate position in Alba, after the enjoyment of the rude liberty and power to which they had been accustomed among their native hills. They therefore requested from their grandfather permission to build a city on the banks of the Tiber, where their lives had been so miraculously preserved. Scarcely had this permission been granted when a contest arose between the two brothers respecting the site, the name, and the sovereignty of the city which they were about to found. Romulus wished it to be built on the Palatine hill, and to be called by his name; Remus preferred the Aventine, and his own name. To terminate their dispute amicably, they agreed to refer it to the decision of the gods by augury. Romulus took his station on the Palatine hill, Remus on the Aventine. At sun-rise Remus saw six vultures, and immediately afterwards Romulus saw twelve. The superiority was adjudged to Romulus, because he had seen the greater number, against which decision Remus remonstrated indignantly, on the ground that he had first received an omen.[1]

Romulus then proceeded to mark out the boundaries for the wall of the intended city. This was done by a plough with a brazen plough-share, drawn by a bull and a heifer, and so directed that the furrow should fall inward. The plough was lifted and carried over the spaces intended to be left for the gates; and in this manner a square space was marked out, including the Palatine hill, and a small portion of the land at its base, termed *Roma quadrata.* This took place on the 21st of April, on the day of the festival of Pales, the goddess of shepherds. While the wall was beginning to rise above the surface, Remus, whose mind was still rankling with his discomfiture, leaped over it scornfully, saying, "Shall such a wall as that keep your city!" Immediately Romulus, or, as others say, Celer, who had charge of erecting that part of the wall, struck him dead to the ground with the implement in his hand, exclaiming, "So perish whosoever shall hereafter overleap these walls." By this event Romulus was left the sole sovereign of the city; yet he felt deep remorse at his brother's fate, buried him honourably, and when he sat to administer justice, placed an empty throne by his side, with a sceptre and crown, as if acknowledging the right of his brother to the possession of equal power.

Romulus, the first king.

To augment as speedily as possible the number of his subjects, Romulus set apart in his new city a place of refuge, to which any man might flee, and be protected from his pursuers. By this device the population increased rapidly in males; but there was a great deficiency of females; for the adjoining states, regarding the followers of Romulus as little better than a horde of brigands, refused to sanction intermarriages. But the schemes of Romulus were not to be so frustrated. In honour of the god Consus, he proclaimed games, to which he invited the neighbouring states. Great numbers came, accompanied by their families; and at an appointed signal, the Roman youth, rushing suddenly into the midst of the spectators, snatched up the unmarried women in their arms, and bore them off by force. This outrage was immediately resented, and Romulus found himself involved in a war with all the surrounding states. Fortunately for Rome, though these states had sustained a common injury, they did not unite their forces in the common cause. They fought singly, and were each in turn defeated; Cænina, Antemnæ, and Crustumerium, fell successively before the Roman arms. Romulus slew with his own hand, Acron, king of Cænina, and bore off his spoils, dedicating them as *spoila opima,* to Jupiter Feretrius. The third part of the lands of the conquered towns was seized by the conquerors; and such of the people of these towns as were willing to remove to Rome, were received as free citizens.

In the mean time, the Sabines, to avenge the insult which they had sustained, had collected together their forces under the command of Titus Tatius, king of the Quirites, or people of the Sabine town of Cures. The Romans were unable to meet so strong an army in the field, and withdrew within their walls. They had previously placed their flocks in what they thought a place of safety, on the Capitoline hill, which, strong as it was by nature, they had still further secured by additional fortifications. Tarpeia, the daughter of the commander of that fortress, having fallen into the hands of the Sabines, agreed to betray the access to the hill, for the ornaments they wore upon their arms. At their approach she opened the gate, and as they entered, they crushed her to death beneath their shields. From her the cliff of the Capitoline hill was called the Tarpeian rock. The attempt of the Romans to regain this place of strength brought on a general engagement. The combat was long and doubtful. At one time the Romans were almost driven into the city, which the Sabines were on the point of entering along with them, when fresh courage was infused into the fugitives, in consequence of Romulus vowing a temple to Jupiter Stator, and by a stream of water which rushed out of the temple of Janus, and swept away the Sabines from the gate. The bloody struggle was renewed during several successive days, with various fortune and great mutual slaughter. At length the Sabine women who had been carried away, and who were now reconciled to their fate, rushed with loud outcries, outspread hands, and dishevelled locks, between the combatants, imploring their husbands and their fathers to spare on each side those who were now to them equally dear. Both parties paused; a conference began, a peace was concluded, and a treaty framed, by which the two nations were united into one. The Sabines built a new city on the Quirinal and Capitoline hills, on the north and north-west of the Roman hill, the Palatine; and Romulus and Tatius became the joint sovereigns of the combined people. But though united, each nation continued to be governed by its own king and senate; and in all that respected their common interest they met in the valley between the Palatine and Capitoline hills, in a place from that circumstance called the Comitium.

---

[1] According to the interpretation of the Etruscan augurs, the twelve vultures seen by Romulus portended that the duration of the city would extend to twelve centuries; and it may strike even an incredulous reader as remarkable, that the actual duration of Rome as a free and imperial city coincided very nearly with the time assigned by this augury. It ended in the 1229th year of the city, by the dethronement of the last emperor Romulus Augustulus.

See Niebuhr, vol. i. p. 224. See also Gibbon, vol. vi. p. 136, Milman's edition.

During the double sway of Romulus and Tatius, a war was undertaken against the Latin town of Cameria, which was taken and made a Roman colony, and its people admitted into the Roman state, as had been done with those whom Romulus previously subdued. Tatius was soon afterwards slain by the people of Laurentum, because he had refused to do them justice against his kinsmen, who had violated the laws of nations by insulting their ambassadors. The death of Tatius left Romulus sole monarch of Rome. He was soon again engaged in a war with Fidenæ, a Tuscan settlement on the banks of the Tiber. This people he likewise overcame, and placed in the city a Roman colony. This war extending the Roman frontier, led to a hostile collision with Veii, in which he was also successful, and deprived Veii, at that time one of the most powerful cities in Etruria, of a large portion of its territories, though he found the city itself was too strong to be taken.

B.C. 721.

The reign of Romulus now drew near its close. One day, while holding a military muster or review of his army on a plain near the lake Capra, the sky was suddenly overcast with thick darkness, the light of the sun was quenched, and a dreadful tempest of thunder and lightning arose. The people fled in dismay; and when the storm abated, Romulus, over whose head it had raged most fiercely, was no where to be seen. A rumour was circulated that during the tempest he had been carried to heaven by his father, the god Mars. This opinion was speedily confirmed by the report of Proculus Julius, who declared, that as he was returning by night from Alba to Rome, Romulus appeared to him in a form of more than mortal majesty, and bade him go and tell the Romans, that Rome was destined by the gods to be the chief city of the earth, that human power should never be able to withstand them, and that he would himself be their guardian god Quirinus.

So terminates what may be termed the legend of Romulus, the founder and first king of Rome. That no person, bearing any resemblance in name and actions, to what is recorded of him, ever existed, it would be perhaps too hazardous to affirm; while it is perfectly evident that the greater part of the narrative is entirely fabulous. The story of Æneas and his Trojans rests upon no better foundation, and has no better claim to be believed. Indeed the various accounts respecting the Trojan leader and colony, are so contradictory as completely to destroy the pretensions of any of them to credibility. All the accounts of the reigns of Ascanius and his successors at Alba Longa, are equally fabulous. The divine paternity, miraculous preservation, and early exploits of Romulus and Remus, are evident fables, of a daringly poetic cast. But that a small strength, a ῥώμη, may have been constructed on the Palatine hill, by some bold and skilful leader of a band of freebooters, about the period assumed for the foundation of Rome, is by no means improbable. A city so founded, by a band so formed, not only might, but evidently must, have passed through a series of contests with the neighbouring cities, similar to those related of Romulus and his people. There may, therefore, be perfect poetical truth, so to speak, in the narrative, though it should be in a great measure devoid of real historical truth. Discarding its miraculous passages, it is sufficiently natural and self-consistent to be received as a traditional account of the adventures, perils, and fluctuating fortunes of the early founders of Rome, of whatsoever race descended, and by whomsoever led.

Numa Pompilius.

Upon the death of Romulus an interregnum took place; during which the senate is reported to have divided itself into ten Decuriæ, each of which governed the state by turns, during periods of five days. At length it was agreed that a king should be chosen out of the Sabine part of the united people, but that the choice should be left to the Romans. Their choice fell upon Numa Pompilius, who is said to have been a citizen of Cures, of noble birth, and greatly distinguished for his wisdom and piety. Upon his election to the sovereignty, he refused to accept it till he had inquired by augury whether it were the will of the gods that he should be king. The omens being favourable, he next laid before the *comitia curiata* the proposal of an enactment by which he should be acknowledged as king, and intrusted especially with full military command. Having received this public and formal recognition of his sovereign power, he then applied himself to the consolidation of the new kingdom and people, by the enactment of laws, and the appointment of whatever pertained to religious worship. To him is ascribed the apportioning of the public territory which had been gained by conquest, to the new people who had become freemen of the Roman state. He determined the extent of the lands to be held by private citizens, marked their boundaries, and fixed them by landmarks consecrated to the god Terminus. Instead of endeavouring to extend the territory of the state, he assigned it also a fixed boundary, restrained the aggressive spirit of the warlike Romans, and strove to mollify them by the cultivation of the arts of peace, and especially by the exact and constant observance of religious rites. He instituted the orders of the priesthood, and determined their respective offices. To the Pontifex Maximus he gave the supreme authority in matters of religion. He appointed the flamens, or priests of the three great gods of the nation, Jupiter, Mars, and Quirinus. To the service of the goddess Vesta he consecrated four virgin priestesses, whose duty it was to tend the ever-burning fire in her temple. By him was formed the institution of the Salii, who honoured Mars Gradivus by solemn songs and dances on appointed festal days, and who were intrusted with the custody of the sacred shield *Ancile*, which fell down from heaven. To him is also ascribed the institution of the college of augurs, whom he himself instructed in the observation of the greater auspices, which were drawn from lightning, and other signs in the heavens.

But in the formation of these sacred institutions, Numa did not solely trust to his own wisdom. He was instructed, says the legend, by the nymph Egeria, who met him in a sacred grotto, and taught him the will of the gods. So highly did she honour, and so dearly did she love him, that she took him to be her husband. To confirm the authority of Numa, and to ratify the laws which he made, and the sacred rites which he taught, Egeria gave to the Romans a token and proof of their divine origin. While Numa was entertaining a party of distinguished citizens, with a meal of homely fare, and served on earthen vessels, Egeria, at his word, changed it into a feast of the most delicious viands in vessels of gold. But though a favourite of the gods, Numa was still mortal. He died full of age and honours, beloved and lamented by all his people, and mourned with ever-flowing sorrow by the nymph Egeria.

B.C. 67

Such is the peaceful and lovely legend of Numa Pompilius, said to have been the second king of Rome, and to have reigned forty years. It is, however, so manifestly poeti-

B.C. 679.

cal, or perhaps mythical, that it is utterly in vain to attempt to extract from it any thing like real history. It may have been merely meant to represent the period of the establishment of forms of laws and religion, which naturally follows that of founding a city and collecting a people. And as all ancient lawgivers assumed divine authority for the sanction of their institutions, so the Roman lawgiver is said to have obtained the instructions of Egeria. The legend is too beautiful to be lost, though too imaginative to be believed; and we turn reluctantly from its evanescent loveliness, to the consideration of matter of a harsher mould.

Tullus Hostilius

An interregnum again followed the death of Numa. At length Tullus Hostilius, a man of Latin or Romish extraction, was chosen by the *curiæ;* and his election having been sanctioned by the auspices, he, like his predecessor, submitted to the *comitia curiata* the laws which conferred upon him full regal power. The new king was more desirous of military renown, than of the less dazzling fame which may be gained by cultivating the arts of peace. An opportunity was soon offered for indulging his warlike disposition. Plundering incursions had been made into each others' territories by the borderers of the two states of Rome and Alba. Both nations sent ambassadors at the same time to demand redress. The Roman ambassadors had private orders from Tullus to be peremptory in their demands, and to limit their stay within the stated period of thirty days. They did so, and receiving no immediate satisfaction, returned to Rome. In the mean time, Tullus amused the Alban embassy by shews and banquets, till, when they opened their commission, he had it in his power to answer, that he had already in vain sought redress from Alba, and that now they must prepare for the events of a war, the blame of originating which was chargeable upon them. By this device Tullus thought to avoid the guilt of being the aggressor, and to secure the favour of the gods by the justice of his cause.

Under the command of Cluilius, the Albans sent a powerful army against Rome, and encamped about five miles from the city. There Cluilius died; and the Albans elected Mettius Fufetius in his stead. Tullus Hostilius, at the head of the Roman army, now drew near the Albans. But when the two armies were ready for a general engagement, Mettius, the Alban general, proposed to save the effusion of blood, by committing the fortune of the war to the valour of certain champions selected from either side. To this proposal Tullus agreed. It so happened that there were in each army three brothers, each three the children of one birth, whose mothers also were sisters, though their fathers belonged to different nations. The three Romans were named Horatii, the three Albans Curiatii. These youthful warriors were chosen to be the champions of their respective nations, and immediately prepared for the combat. It was agreed, that by the issue of this contest should be determined the dominion or subjection of each people. The two armies were drawn up in battle array, each on their own side of the boundary line that divided their territories. The young combatants advanced, and met on the very line. The combat began, and was sustained for some time with equal skill, courage, and ardour, while the two armies gazed on the eventful struggle with the suspended breath of intense anxiety. At length two of the Horatii fell at the feet of their antagonists; a sight which called forth loud shouts of joy from the Albans, while the Romans remained quivering with suspense for the fate of their remaining champion, and the freedom of their country. Horatius was still unhurt, whilst the three Curiatii were all severely wounded. Believing himself more than a match for each singly, he feigned a flight to divide them. They pursued with unequal strength and speed, and were separated to considerable distances from each other. On a sudden he turned, rushed on the enemy nearest him, and slew him at a blow. With equal impetuosity he assailed and killed the second, while the third was hastening to render his brother aid. There was now but one combatant on either side, yet it could no longer be called a battle. Faint, exhausted, and dispirited, the third of the Curiatii sunk beneath the vigorous arm of the victorious Roman, who thus at once avenged his brothers, and won for his country the sovereign sway.

As the Romans were returning in triumph to the city, Horatius bearing the triple spoils, they were met at the Capenian gate by his sister, who had been betrothed to one of the Curiatii. When she beheld the bloody mantle of her lover, which she had wrought with her own hands, borne aloft by her brother, she burst into loud lamentations, flinging loose her scattered locks. Horatius, enraged at her untimely grief and outcry, drew his sword and pierced her to the heart, exclaiming, "So perish the Roman woman that shall bewail a foe." For this fierce deed, Horatius was by the judges condemned to death. But he appealed to the people, and his father defended him, saying, that if his daughter had not deserved to die, he would himself have punished his son, in virtue of his own authority as a father. The people refused to stain the victory which Horatius had achieved for his country by shedding the blood of the conqueror, and therefore spared his life, but caused him to undergo the semblance of capital punishment, and perform certain expiating sacrifices and rites, which thenceforth became hereditary in the Horatian family.

Notwithstanding the agreement which had been entered into between the Romans and the Albans, the latter were unwilling to forfeit their national independence without an additional struggle. This, however, they were desirous to avoid provoking single-handed. They accordingly encouraged the people of Fidenæ to revolt, by giving them secret promises of assistance. Tullus Hostilius immediately levied a Roman army, and summoned the Albans to his aid. The two armies met, the Veientes being drawn up opposite to the Romans, and the Fidenates confronting the Albans. When the battle began, Mettius Fufetius, the Alban leader, wanted courage and decision to fulfil his own treacherous pledge; he neither joined the Romans nor the Fidenates, but drawing his men off from the conflict, stood aloof, to watch the event and act accordingly. His defection struck a temporary panic into the Romans, which was speedily allayed by the bravery and skill of Tullus; and his remaining aloof caused distrust in the Fidenates, who finally fled before the vigorous onset of their antagonists. Tullus gained a complete victory; and concealing his knowledge of the treachery of Mettius, next day called an assembly of his whole army. The Albans came unarmed, and arrived first. The Romans came next, wearing, as they had been directed, their swords hid beneath their mantles, and at a signal surrounded the Albans. Tullus then denounced the treachery of Mettius, and commanded him to be torn asunder by two chariots of four horses, as his mind had been divided between the Romans and the Fidenates in the battle. It was then decreed that Alba should be razed to the ground, and the whole Alban people removed to Rome, to prevent the possibility of future strife. Not only the walls of Alba, but every human habitation, was totally demolished, and the temples of the gods alone left standing in solitary majesty amid the ruins.

But though Tullus had thus put an end to the separate existence of Alba, he did not reduce its inhabitants to slavery. He assigned them habitations on the Caelian hill, which had formerly been possessed by the followers of the Etruscan Lucumo, Caeles Vibenna. Those who had been of patrician rank at Alba were allowed to retain the same rank at Rome, and a new tribe was formed, called the Luceres. The construction and numbers of this tribe were the same as those of the other two; so that the entire senate, composed of the heads of houses of the three tribes amounted now to 300, which continued to be its stated number.

Soon after these events, Tullus made war upon the Sabines, and in a bloody, and for some time doubtful encounter, again obtained the victory. Another war arose with the confederate towns of Latium, who began to dread the growing power of Rome after the destruction of Alba. The Latian war terminated without any decided reverses sustained by either party; and an alliance was formed between the Romans and the Latins. Tullus had now leisure to direct his attention to the arts of peace, in which, however, he did not equally excel. The only public works ascribed to him were the enclosing of a space for the Comitium, or assembly of the people; and the building of a Curia, or senate-house. Towards the end of his reign his mind was disturbed by prodigies, indicating the wrath of the gods, for religion neglected, and temples left desolate. A shower of stones fell from heaven on the Alban mount; and the awful accents of a supernatural voice were heard to issue from the consecrated summit of the hill. A plague swept away numbers of the Roman people. The king himself sickened; and from having been neglectful of religion, became the slave of superstitious terrors. In vain did he supplicate the gods. He had disregarded them in his days of prosperity, and in his adversity no deity regarded his prayers, or sent relief. In his despair he presumed to use the divinations of Numa, by the rites of Jupiter Elicius; but the only answer returned was the lightning of the offended gods, by which Tullus himself and his whole household were smitten and consumed. Such is the legend of Tullus Hostilius, said to have been the third king of Rome. B.C. 640.

After the death of Tullus Hostilius there followed another interregnum, during which the senate, as usual, exercised the functions of sovereignty. An assembly was then held, in which Ancus Marcius, a son of the daughter of Numa, and a Sabine by race, was chosen king. He assumed the sovereignty with the usual formalities, receiving the sanction of the comitia curiata. Ancus seems to have taken the conduct and character of Numa for his model rather than those of his more warlike predecessors. His first object was to restore those religious rites which had been neglected by Tullus; and for this purpose he caused the institutions of Numa to be inscribed on tables, and suspended in public places, that all might read, know, and observe them.

Ancus Marcius.

While he was thus busied in restoring religious worship, the Latins imagined they might recover that power which had been wrested from them by Tullus. They soon found that Ancus, though peacefully inclined, was by no means incapable of resenting injuries. He raised an army, encountered the insurgent Latins, and after a severe struggle, not only defeated them in the field wherever he met them, but also took from them several cities, whose inhabitants he removed to Rome, and settled on the Aventine hill, on the south of the Palatine. On the left bank of the Tiber he prosecuted his conquests till he reached the sea, where he built Ostia, and settled a colony in it to secure it as a permanent conquest, and that it might be a sea-port for Rome. He obtained also some advantages over the Sabines and Veientines; and to render his intercourse with the right bank of the river both more easy and more secure, he formed a wooden bridge across the Tiber, and fortified the hill Janiculum. The oldest remaining monument of Rome, the prison, formed out of a stone quarry on the Capitoline hill, is also said to have been the work of Ancus. He died in peace, respected and beloved, and was known in tradition by the designation of "the good Ancus." B.C. 618.

That part of Roman history at which we have now arrived, is at once characterized by great interest and by great obscurity. It has the appearance of a great poem, containing just enough of fact to give it credibility in the ears of willing listeners, and enough of fiction and embellishment to destroy all its pretensions to the severely simple character of history. In our opinion this is its real character; and we are by no means disposed to discard more of it than seems of itself to assume no claim upon our belief. No reader can possibly mistake poetic ornament for fact; but there is one aspect of the narrative in which the common reader may be mistaken. It is not enough that an event be strange, or even almost marvellous, in order to be discredited. Many things are abundantly strange in our eyes which nevertheless did actually occur. The wild, strange, and daring exploits recorded of the early founders of nations are liable to be disbelieved by posterity, in the exercise of its cool philosophic criticism. But the founders of a nation are generally men of daring and enthusiastic character, whose actual deeds are constantly hovering on the brink of the incredible. Nations, like individuals, have a period of youth, in which their history is naturally full of deeds of lofty daring, strange adventure, and all but miraculous exploit. The most truthful narrative of a nation's youth must contain accounts of those deeds of scarcely imaginable hardihood; and such a narrative will seem utterly unworthy of belief to the cool philosopher of a calmer and more thoughtful age. Hitherto we have been attempting to obtain a glimpse of the very infancy of Rome; now we are to view the exploits of its fiery and impetuous youth. We are not lightly to credit every miraculous statement that claims our attention; but neither are we to demand a succession of events regulated by a cool deliberate prudence, such as our own habits of thought and action could alone approve.

In the days of Ancus Marcius a noble and wealthy Tuscan sought a residence in Rome. He was the son of a citizen of Corinth of some distinction, who had left his native country to avoid the tyranny of an usurper. Having settled at Tarquinii, a city on the coast of Etruria, he married an Etruscan lady of the highest rank. His son, in virtue of his mother's rank, belonged to the ruling caste of Etruria, the Lucumones; but the pride of that caste would not permit them to suffer a person of mixed descent to participate in their hereditary honours. He married an Etruscan lady of the noblest birth, Tanaquil by name, who could not brook that her husband should be disparaged by her haughty kindred. They left Tarquinii, and journeyed to Rome, in the hope of being received by Ancus in a manner more suited to their dignity. They had reached the brow of the Janiculum, and were in sight of Rome, when an eagle hovering over them, stooped, snatched his cap, and after soaring aloft with it to a great height, again descended and placed it on his head. Tanaquil, versed in the lore of Tuscan augury, understood the omen, and embracing her husband, bade him proceed joyfully, for the loftiest fortunes awaited him. He was received as a Roman citizen, and assumed the name of Lucius Tarquinius. His courage, his wisdom, and his wealth, soon recommended him to the favourable notice of the king, and made him greatly esteemed also by the people generally. On the death of Ancus he was chosen king, and received from the assembly the customary sanction to his assumption of sovereignty.

Tarquinius Priscus.

Scarcely was Tarquin seated on the throne when the Latin states broke the treaty which they had made with Ancus, and began to make inroads upon the Roman territory. Tarquinius marched against them, defeated them in battle, and took and plundered Apiolae, where he obtained an immense booty. Prosecuting his victorious career, he made himself master of Cameria, Crustumerium, Medullia, Ameriola, Ficulnea, Corniculum, and Nomentum. The Æqui also felt the power of his arms, and were obliged to humble themselves before him. While he was engaged with the Latins, the Sabines availed themselves of his absence, mustered their forces, crossed the Anio, and ravaged the country up to the very walls of Rome. Tarquinius returning from his Latin wars, encountered the Sabines, and after a desperate conflict, drove them from the Roman territories. Next year they again passed the Anio by a bridge of boats, and advanced towards Rome. Tarquinius met them in battle, and by the superiority of his cavalry gained a complete victory. During the battle a party of Romans, sent for that purpose, burned the bridge of boats, so that the routed Sabines were cut off from their retreat, and driven into the river, where great numbers of them perished. Their bodies and arms, floating down the Tiber, brought the first intelligence of the victory to Rome. He then crossed the river, inflicted upon them a second defeat, and compelled them to surrender the town and lands of Collatia, which they had previously taken from the Latins. Tarquinius placed a strong garrison in the town, and assigned the capture to his brother's son, who thence took the name of Collatinus. In this war the king's son, a youth of fourteen, slew a foe with his own hand, and received as a reward of honour a robe bordered with purple, and a hollow ball of gold to be suspended round his neck; and these continued to be the distinctive dress and ornament of the Roman youth of patrician rank, till they assumed the *toga virilis*, or manly gown.

Tarquinius is likewise said to have engaged in war with the Etruscan nations, to have taken several of their cities, and to have overthrown them, notwithstanding a confederacy of all their twelve states against him. In token of their submission to his power, the Etruscans at length sent him a golden crown, an ivory throne and sceptre, a purple tunic and robe figured with gold, and twelve axes bound up in bundles of rods to be borne before him, such as they used when their twelve cities chose a common leader in war. These, by the permission of the people, Tarquinius adopted as the insignia of kingly power; and, with the exception of the crown, and of the embroidered robe, they remained as such both to his successors on the throne, and to the consuls, unless on the days when they went in public triumph to the Capitol.

Such were the military exploits ascribed to Tarquinius; and there is nothing so improbable in them as to startle our belief. It is indeed manifest from other indications, that about the period assumed as the reign of Tarquinius Priscus, as he is called for the sake of distinction, the dominions of Rome must have comprised nearly all the territory which he is said to have conquered, and also that the city must have risen to great wealth and power. The latter point is proved by the great public works, which all accounts agree in ascribing to him. He built the cloaca maxima, or great sewers, to drain off the water from between the Capitoline and Palatine, and the Palatine and Aventine hills. This vast drain was constructed of huge blocks of hewn stone, triply arched, and of such dimensions, that a barge could float along in it beneath the very streets of the city. Earthquakes have shaken the city and the adjacent hills; but the cloaca maxima remains to this day unimpaired, an enduring monument of the power and skill of the king and the people by whom it was constructed. The Circus Maximus, or great race-course, was also a work of this monarch, intended for the display of what were called the great, or Roman games, "ludi magni Romani." The forum, with its rows of shops, was also the work of Tarquinius; and he began to surround the city with a wall of massy hewn stones. He likewise made preparation to fulfil a vow to build a great temple on the Capitoline hill to the chief deities of Rome.[1]

To conclude the legendary history of Tarquinius, he is said to have been murdered by the treachery of the sons of his predecessor Ancus Marcius. They, perceiving the favour with which the king regarded Servius Tullius, and fearing an attempt to make him king, to the exclusion of their own pretensions and hopes, hired two countrymen to pretend a quarrel, and to appear before the king seeking redress. While he was listening to the complaint of one, the other struck him on the head with an axe, and then they both made their escape. The conspirators did not, however, obtain the fruit of their treachery. Tanaquil gave out that the king was not dead, but only stunned by the blow, and had appointed Servius Tullius to rule in his name till he should recover. Servius immediately assumed the ensigns and exercised the power of royalty. The murderers were seized and punished, and the Marcii fled disappointed from the city. When the death of Tarquinius could no longer be concealed, the power of Servius was so well established, that the people were perfectly ready to grant him the usual confirmation in the powers of the sovereignty.

B.C. 578.

Servius Tullius.

The accounts respecting the origin of Servius Tullius are as obscure as those of any of his predecessors. The most ancient and poetical legend represents him as the son of Ocrisia, a captive and slave of Tanaquil the queen, by the Lar, or household god. Later legends made him a son of one of the king's clients, and for sometime a slave; or the son of a man of rank and power in one of the conquered Latin cities, who being slain in the war, his widow was carried to Rome in her pregnancy, and she and her infant son were protected by Tanaquil.[2] All accounts represent him as enjoying the favour of Tarquinius and his queen, and obtaining the throne in a great measure by the judicious management of the latter. It would seem as if Servius had in the very beginning of his reign encountered the opposition of the patricians. He is said not to have allowed any interregnum, or to have permitted the senate to take the lead in his election to the sovereignty; but as he had already acted as king before the death of Tarquinius was publicly known, so to have made a direct application, without any other preliminary process, to the comitia curiata, and to have been by them invested with the powers of former kings. The only historical conclusion which can be deduced from these incidental notices is, that a contest had begun between the kings and the patrician body, in which the kings deemed it their soundest policy to diminish the power of the patricians, in order to maintain their own. But as no direct diminution of their power could have been attempted without exciting an immediate insurrection, it was deemed expedient by these kings to raise a counterbalancing power in the state, which, having received its existence from them, might be expected to lend them aid in repressing the exorbitant power of the patrician body, combined with their hereditary privileges.

This view, it will be observed, both coincides completely with the tradition that Tarquinius first elevated the tribe of the Luceres to the possession of full senatorial power; and with the tradition that his very coming to Rome was caused by the pride of the privileged and hereditary order of Lucumones, who had excluded him from participating in the honours to which he thought himself entitled both by birth and merit. Finding at Rome also a patrician class, in the possession of hereditary powers and privileges, he not unnaturally regarded them with jealousy, and endeavoured to call into being a counterbalancing power, by which his influence might not only be maintained, but rendered predominant. The policy pursued by all the kings of the Etruscan line entirely accords with this view, so as to give it at least an air of great probability.

---

[1] This mention of the building of temples on the Capitoline hill to the chief deities of Rome by Tarquinius Priscus, refers in all probability to the introduction to Rome of the refined and poetical idolatry of Greece, and receives some colouring of credibility from the account of his descent from a native of Corinth. Beaufort proves, that for the first 170 years of its existence at least, there were no images at Rome, unless the rude block of stone called the god Terminus might be considered an image. See *La Republique Romaine*, par M. de Beaufort.

[2] Another account of the origin of Servius has been preserved by a speech of the emperor Claudius, as given in the Etruscan Annals. Claudius begins to recount how often the form of government had been changed, and even the royal dignity bestowed on foreigners. Then, he says of Servius Tullius, "According to our Annals, he was the son of the captive Ocrisia; but if we follow the Tuscans, he was the faithful follower of Caeles Vibenna, and shared all his fortunes. At last, driven by various fortunes, he quitted Etruria with the remains of the army which had served under Caeles, went to Rome, and occupied the Caelian hill, giving it that name after his former commander. He exchanged his Tuscan name, Mastarna, for a Roman one, obtained the kingly power, and employed it to the great advantage of the state." See Niebuhr, vol. i. p. 381.

The twelve Etruscan cities which had acknowledged the dominion of Tarquinius, revolted on hearing of his death. They were speedily reduced to subjection by Servius, for which military success he was decreed a triumph by the people. But his triumphs in war were not to be compared with his triumphs in peace. Finding the population of Rome increasing rapidly, he enlarged the pomœrium, or sacred boundary of the city. When first formed by Romulus, the pomœrium included merely the Palatine hill and a portion of the plain at its base. It was extended by Numa so as to include the Capitoline and Quirinal hills, in consequence of which the Sabine town became completely incorporated with the Roman. Servius again enlarged it, so as to bring within its compass the Viminal and Esquiline hills, in addition to those which were the appropriate seats of the great tribes. He finished the work begun by Tarquinius, by building the walls of the city of hewn stone; and where the hills which he had included in the new addition to the city sloped gently down towards the plain, he fenced them by a large mound of earth, and a moat from which the earth of the mound was dug. For the purpose of consolidating more firmly the union of the races of which the nation was composed, he built the temple of Diana on the Aventine hill, which was to be the chief abode of the Latin population recently brought to Rome. This temple constituted a monument of the league between the Roman people and the thirty confederate Latin towns; and, although Romans, Sabines, and Latins sacrificed there in common, yet, as Rome was now recognised as the head of the confederation, the Romans were allowed to have the precedency.

But the most important achievements of Servius Tullius, were his alterations of, and additions to, the constitutional principles of the state. Incidental notices have already been given respecting the origin and development of the Roman constitution, so far as the obscurity of the traditional narratives and poetic legends have furnished scope for the treatment of such topics. To these we shall subsequently advert; but we must now prosecute the historical narrative, so far as it can be called historical; for there is no part of ancient Rome that more evidently abounds with poetic legends than the conclusion of the kings, and the first years of the commonwealth. Fortunately there is no absolute necessity to discard the poetic legends; for however destitute they may be of what is termed historical truth, there can be no question but that they present a very accurate and lively picture of the times and events in which they are said to have taken place.

Servius Tullius had given his two daughters in marriage to the two sons of Tarquinius Priscus. These daughters were of tempers very unlike, as were also their husbands. The elder, Tullia, was of a gentle disposition, her younger sister fierce, imperious, and ambitious. Aruns Tarquinius was of a mild and quiet character, his brother Lucius proud, restless, and domineering. To counteract these tempers, Servius had given the gentle princess to the ambitious prince, and made the haughty damsel wife to the mild husband. But this dissimilarity of temper did not produce the effect which he had expected. The fiery tempered of each couple became dissatisfied with the one of gentler nature; the milder wife and husband perished by the crimes of their aspiring mates, who were speedily united in a second shameless marriage. Then did the aspiring temper of the one urge on the haughty and ambitious heart of the other, till they resolved to make way to the throne by the murder of the good old man, their king and father. To this attempt Lucius was encouraged by the unconcealed dissatisfaction of the patricians with the influence obtained by the plebeians in the new constitution. Their dissatisfaction was increased by a rumour that Servius intended to abolish the monarchical form altogether, and divide the sway between two consuls, one to be chosen from the patrician, and one from the plebeian body. Having formed a strong faction among the patricians, Tarquinius went to the senate-house, seated himself in the royal chair, and summoned the senators to meet king Tarquinius. Servius having heard the rumour, hastened to the senate-house, accused Tarquinius of treason, and laid hold of him to remove him from the royal chair. The usurper instantly seized the old man, dragged him to the door, and threw him with great force down the steps. There he lay for a few moments stunned and bleeding with the fall; then rising slowly staggered away towards his palace. Some ruffians employed by Tarquinius, pursued, overtook, and killed him, leaving the body lying bleeding in the street. Meantime, tidings of what was going on had reached Tullia, who immediately mounted her chariot, drove to the senate-house, and saluted Tarquinius as king. He bade her withdraw from such a tumult; and she, on her return, passed along the same street where lay the bleeding body of her newly murdered father. The mules shrunk, the charioteer stopped short, and pointed out the appalling spectacle. In a loud and imperious tone of voice she commanded him to drive on; the chariot wheels rolled over the yet warm form, crushing and mangling it as they proceeded, till the spurting blood stained the robes of the more than parricide. From that hour, in remembrance of that hideous scene, the street was called the Vicus Sceleratus, or Wicked Street.

B.C.

Tarqui
Superb

Tarquinius having thus obtained forcible possession of the throne, declined to submit to the form of an election, or to make the customary appeals to the comitia curiata for the ratification of his kingly power. He seized the crown as if it were hereditary; and seemed resolved to rule without the concurrence of any of the great assemblies. But as he had been raised to the throne by the aid of the patricians, his first act was to gratify them by repealing the privileges which Servius had granted to the plebeians. He suppressed the institution of the comitia centuriata, and even prohibited the meetings of the country tribes at the paganalia. But this was only the beginning of his tyranny. He depressed the commons or plebeians; but he had no intention to permit the power of the patricians to become too strong, especially as he was himself but too well aware of their treachery to the former king. He therefore surrounded himself with a bodyguard, the ready instruments of his oppression; and, under colour of justice, banished or put to death, on false accusations, all who were either too powerful or too wealthy to be trusted, or whom he suspected of disaffection to himself. In this manner he reduced the patricians into a state of subjection almost as deep as that into which they had assisted him to reduce the plebeians.

Being now possessed of nearly despotic power, he turned his attention to the enlargement of his kingdom. He gave his daughter in marriage to Octavius Mamilius of Tusculum, the most powerful of the Latin chiefs; and partly by intrigues, partly by force, he procured Rome to be acknowledged the head of the Latin confederacy. Herdonius, the only man who dared to oppose his proud demeanour, he caused to be put to death by false accusations, and completely incorporated the Latin troops with those of Rome. The Hernici were also included in this confederacy. One

Latin city, Gabii, refused to join this league, and was assailed by Tarquinius. The struggle was long and severe; but at length Tarquinius is said to have obtained possession of it by means of a stratagem, conducted by his son Sextus, similar to that by which Zopyrus gained possession of Babylon for Darius Hystaspis. He turned his arms next against the Volsci, and took Suessa Pometia, where he obtained a very great booty, and retained the tithe of it for his own share.

Thus powerful and enriched, he next proceeded to finish the great works left incomplete by his predecessors. He finished the cloaca maxima, and prepared to build the temple which his father, during the Sabine war, had vowed to the three great deities, Jupiter, Juno, and Minerva. For this purpose he levelled the brow of the hill, originally called by the Sabines Saturnius, but better known by its subsequent name, the Capitoline hill. In clearing away the ground for the foundation of this temple, a fresh human skull was found; whence the augurs predicted that Rome should be the capital, or chief city of the world; whence also the name by which that hill was always subsequently known. The hill had formerly been almost covered with altars and shrines consecrated by the Sabines. Tarquinius inquired by augury whether the deities, to whom these were sacred, would yield their places to Jupiter, Juno, and Minerva. The auguries allowed the removal of all except the shrines of Terminus and Youth. This was interpreted as itself an omen, that the boundaries of the Roman empire should never recede, and that the state should be for ever young.

The chief builders of the capitol were Etruscan workmen, whose skill was superior to that of the Romans; but Tarquinius compelled the Roman commons to work also as labourers, giving them merely a certain supply of provisions daily, as if they were mere slaves. They groaned wearily underneath his heavy yoke, but he ruled them with a high hand, and sent colonies of the most refractory of them to the frontiers of his conquests in the Volscian lands. Under the strong and imperious sway of this haughty, yet able tyrant, Rome reached an extent of territory and a pitch of power greatly beyond what it had ever before attained. There may, however, be the aspect of external greatness, and the reality of internal wretchedness; but such a state of affairs cannot be permanent.

Hitherto, the narrative diverges little from the plain course of what was, or might have been, historical truth; and it is not undeserving of remark, that the conduct of Tarquinius Superbus is very natural for a prince who retained much of the Etruscan notions respecting hereditary rights, and scorn of the lower classes. The plan of employing the plebs in task-work, without any other support than a scanty allowance of food, might have been brought from the Nile, as easily as from Etruria; and is some corroboration of the theory which would bring the hereditary half priest half noble caste of Lucumones from Egypt.

About this time the strange story of the Sibyl is told. An unknown woman, of foreign aspect and manners, came to the king and offered him nine books of prophecies, for which she demanded a large sum. The king refused. The woman departed, burnt three of the books, and then returned and demanded the same sum for the remaining six. The king still refused; and again the woman went away, burnt three, and returning, demanded the same price as at the first. Struck by this strange conduct, Tarquinius consulted the augurs, who told him that it was essential to the safety of Rome to procure the books. Accordingly he purchased them, and the woman departed, and was seen no more. These Sibylline books were then deposited in a chest of stone, and entrusted to the charge of two men of the highest rank, who kept them under ground in the Capitol. Their contents were never divulged; nor were they ever consulted, except by a decree of the senate, and in times of the greatest public danger and distress.

But the tyranny of Tarquinius had now nearly reached its limits. Various portents foreshewed its approaching overthrow. According to the legend, the first indications of the coming doom were seen in an unnatural violation of the sacred rites. A huge snake crawled out from an altar in the court of the palace, in the time of sacrifice; the fire suddenly died out, and the snake devoured the victim. To ascertain what this prodigy portended, the king sent two of his sons to consult the oracle of Apollo at Delphi. They took with them their cousin, Lucius Junius Brutus, who had been brought up along with them in the palace, disregarded on account of his apparent apathy of manner, and laughed at as almost half an idiot. He was the younger son of a sister of Tarquinius by Marcus Junius; and his elder brother had been put to death by his uncle for his wealth. To escape a similar fate he had feigned idiocy, and was consequently spared and despised. So runs the legend, to account for the name Brutus; which, however, in old Latin is nearly synonymous with Severus, and may have been given him merely on account of his reserved gravity of manner. The answer of the Delphic oracle was, that the king should fall when a dog should speak with a human voice. This response was of course intended secretly to apply to Brutus, and his unexpected display of mental ability. The young princes also asked which of the king's sons should succeed him; and were answered in general terms, that the regal power should be enjoyed by the person who should first salute his mother. Brutus, as they were departing, stumbled, fell, and kissed the earth, thus fulfilling the meaning of the oracle.

Soon after this event, Tarquinius waged war against Ardea of the Rutuli, a people on the coast of Latium. The city was very strong both by nature and art, and made a protracted resistance. The army lay encamped around the walls, in order to reduce it by hunger, since they could not by direct force. While lying half idle at Ardea, the princes and their kinsmen, Brutus and Collatinus, happening to feast together, began in their gaiety to boast each of the beauty and virtue of his wife. Collatinus extolled his wife Lucretia as beyond all rivalry. On a sudden they resolved to ride to Rome and decide the dispute by ascertaining which of the respective ladies was spending her time in the most becoming and laudable manner. They found the wives of the king's sons entertaining other noble ladies with a costly banquet. They then rode on to Collatia; and though it was near midnight, they found Lucretia with her handmaids around her working at the loom. It was admitted that Lucretia was the most worthy lady; and they returned again to the camp at Ardea.

But the beauty and virtue of Lucretia had excited in the base heart of Sextus Tarquinius the fire of lawless passion. After a few days he returned to Collatia, where he was hospitably entertained by Lucretia as a kinsman of her husband. At midnight he secretly entered her chamber; and when persuasions were ineffectual, he threatened to kill her and one of her male slaves, and laying the body by her side, to declare to Collatinus that he had slain her in the act of adultery. The dread of a disgrace to her memory, from which there should be no possible mode of wiping away the stain, produced an effect which the fear of death could not have done; an effect not unnatural in a heathen, who might dread the disgrace of a crime more than its commission, but which shews the conventional morality and virtue of the time, how ill-founded, and almost weakly sentimental, in even that boasted instance of female virtue. Having accomplished his wicked purpose, Sextus again returned to the camp.

Immediately after his departure, Lucretia sent for her husband and father. Collatinus came from the camp accompanied by Brutus; and her father, Lucretius, from the city, along with Publius Valerius. They found Lucretia sitting on her bed, weeping and inconsolable. In brief terms she told what had befallen her, required of them the pledge of their right hands that they would avenge her injuries, then drawing a knife from under her robe, stabbed herself to the heart and died. Her husband and father burst into a loud cry of agony; but Brutus snatching the weapon from the wound, held it up, and swore by the chaste and noble blood which stained it, that he would pursue to the uttermost Tarquinius and all his accursed race, and thenceforward suffer no man to be king in Rome. He then gave the bloody knife to her husband, her father, and Valerius, and called on them to take the same oath. Brutus thus became at once the leader of the enterprise. They bore the body of Lucretia to the market place. There Brutus addressed the people, and moved them to vengeance. The youth immediately enrolled themselves into an army. Part remained to guard the city, and part proceeded with Brutus to Rome. Their coming raised a tumult, and drew together great numbers of the citizens. Brutus, availing himself of his rank and authority, as tribune of the celeres, or captain of the knights, summoned the people to the forum, and proceeded to relate the bloody deed which the villany of Sextus Tarquinius had caused. Nor did he content himself with that, but set before them in the most animated manner the cruelty, tyranny, and oppression of Tarquinius himself; the guilty manner in which he obtained the kingdom, the violent means he had used to retain it, and the unjust repeal of all the laws of Servius Tullius, by which he had robbed them of their liberties. By this means he so effectually roused the people, that they passed a decree abolishing the kingly power itself, and banishing for ever Lucius Tarquinius Superbus, and his wife and children. In the midst of the tumult the wicked Tullia fled from her house and the city, pursued by the curses of the whole population wherever she passed, imprecating upon her head the vengeance of the furies, for the murder of her sister, husband, and father.

Intelligence of the tumult had in the mean time reached the camp at Ardea. Tarquinius hastened to the city, if possible to suppress it; and Brutus, assigning the command of the city to Lucretius, set out himself for the camp, taking a different road, so as to avoid meeting the dethroned usurper. When he reached the camp he soon roused in the army the same indignation against the tyrant, which had blazed so strongly at Rome. The commanders of the troops joined him; the army adhering to the observances of the comitia centuriata, confirmed in legal form the decree of the citizens, banishing the Tarquin family, and abolishing the regal name and power for ever. They then made a
B.C. 509. truce with the Ardeans for fifteen years, and marched towards Rome. Tarquinius, finding the gates shut against him, and learning the defection of the army, fled with his sons to Caere in Etruria. Thus ended the reign of Tarquinius Superbus; and with it the existence of the monarchical form of government at Rome.

The first consuls.

The monarchical form of government being thus abolished, the next step was to constitute another in its stead. Lucretius was appointed *inter-rex*, and the comitia centuriata were held by his authority in the Campus Martius, when Brutus and Collatinus were chosen to be supreme magistrates, at first with the name of prætors, which was afterwards changed to that of consuls, by which title, as the better known, we shall continue to designate these colleagues in the chief power. They retained all the power of the kings, and all the insignia of royalty, except the diadem; but the rods and axes, the emblems of the power of life and death, were carried before each alternately for a month. In order that the sacred rites might be duly performed, they appointed a priest with the title of *king of the sacrifices*, but without political power. They then proceeded to fill up the due number of three hundred in the senate, which had been diminished partly by the tyranny of the last king, and partly by the flight of his adherents, who were implicated in his crimes. They restored those laws of Servius Tullius which were favourable to the commonalty; and re-appointed the meetings and common sacrifices of the tribes.

Rome seemed now to have regained its liberties, but it had not obtained the sense of security. It was thought necessary to banish Collatinus, who was the nephew of Tarquinius, that there might remain none of that hated race in the city. Collatinus yielding without a struggle, withdrew to Lavinium, and there died in old age. Publius Valerius was elected consul in his stead, by the comitia centuriata.

It was not to be expected that the banished king would submit without a contest. He first attempted to induce the Latin states to espouse his quarrel; and finding them unwilling, he applied to the Etruscans. Ambassadors were sent from Etruria to demand the restitution of his private property. This demand gave rise to warm discussions, whether they should obey justice by giving up the private property of Tarquinius, or prudence, by refusing to put money into the hands of an enemy, which they foresaw would soon be used against themselves. The plea of justice prevailed, and the property was ordered to be restored. But during the discussion, and the period required for collecting the property, the Etruscan ambassadors were intriguing with the younger patricians in the formation of a plot to restore the king. Considerable numbers of the more haughty of them, offended with the favour shewn to the commons, joined in the conspiracy, among whom were the two sons of Brutus himself. The conspiracy was discovered by the information of a slave, who had overheard them while concocting this plot in secret. The two consuls called the people to the comitium, and commanded the conspirators to be brought bound before them. The whole plot was detected; the Etruscan ambassadors permitted to depart uninjured, out of respect to the laws of nations; and the convicted traitors thrown into prison to await their trial. Next day the trial was conducted in public, and sentence of condemnation passed. Brutus commanded the sentence to be put in execution upon his own sons. They were stripped, beaten with rods, and then beheaded. Nor till this fearful example of stern retributive justice had been completed did Brutus leave the assembly; and when he departed, the people could do no less than inflict an equal doom on the remaining conspirators.

The private danger was thus turned aside, but a public tempest was at hand. The Etruscan cities of Tarquinii and Veii took up arms in the cause of the banished king, and advanced against Rome. The Romans crossed the Tiber to encounter the foe; and the two armies met near the grove of Arsia. Before the battle began, Brutus, who was riding at the head of the Roman cavalry, was descried by Aruns Tarquinius, who led those of Etruria. The banished prince, burning with personal hatred, spurred his steed furiously against the consul. Brutus, with equal animosity, met him in mid career; and in the shock each pierced the body of his antagonist with his spear, and they fell wounded and dying together to the ground. The cavalry on each side hastened to avenge their leaders; the battle became general; each right wing was victorious over its opponent; and after a long and bloody struggle, night put an end to the undecided contest. Both parties kept the field; but in the dead of night a voice was heard from the adjacent grove, declaring that the Etruscans had lost one man more than the Romans, who were, and would be victorious. A panic seized the enemy, they deserted their camp and fled; and at dawn the Romans found nothing to do but to carry off the booty. Valerius returned to the city in triumph, and in the forum pronounced a funeral oration over the body of Brutus. The matrons mourned for him a whole year, and his statue was placed in the Capitol, among the kings, with a sword in his hand.

After the death of Brutus, Valerius for a time retained the consular power alone; not from ambition, but probably that he might, unobstructed, pass those laws which he deemed necessary for the public welfare. He enacted a law, by which every person who should seek kingly power was pronounced accursed, so that any man might kill him without fear of punishment. In the presence of the assembly of the people, (the populus, *i. e.* the comitia curiata,) he caused the ensigns of consular power to be lowered; thus acknowledging the supreme authority of that assembly. But his best act was the passing of that law, *(lex de provocatione,)* which gave to all Roman citizens the right of appeal to the assembly of the people from the sentence of any magistrate. This was the first law enacted by the comitia centuriata; and as soon as it was passed Valerius took away the axes from the bundles of rods which were borne before the consuls. This right of appeal existed only in the city itself, and within a mile of it. Beyond that distance the military power of the consuls remained unlimited, and the axes were borne and used as formerly. The enactment of these laws obtained for Valerius the surname of Poplicola.

B. C. 508.

As soon as they were passed, he held the comitia for the election of a consul in the room of Brutus. Spurius Lucretius was chosen; and he dying within a few days, Marcus Horatius Pulvillus was elected to complete his year. About this time occurred that famous treaty between Rome and Carthage, mentioned by Polybius, and which is perhaps the best proof of the power of Rome under her latter kings. Ardea, Antium, Aricia, Circeii, and Terracina, are mentioned in such terms as to cause them to be regarded as subject cities, and Rome stipulates for them as well as for herself. The treaty was signed by Brutus and Horatius; whence a difficulty has arisen, as these two were not at any time colleagues in the consular office. But Gibbon[1] has shewn that such treaties were signed by the *feciales* more properly than by the consuls; and there is no reason for doubting that Brutus and Horatius may have been conjoined in that office.

War with Porsenna.

In the mean while Tarquinius, finding the inability of the Veientians and Tarquinians to replace him on the throne, applied to Lars Porsenna, king of Clusium, at that time the most powerful of all the Etruscan monarchs. Porsenna raised a great army, and marched towards Rome. He was met by the Romans near the fortress on the Janiculum; but almost at the first encounter they took to flight, and the Etrurians pursued them impetuously as they sought safety by crossing the bridge. Horatius Cocles, seeing the danger that the city might be taken at once if the enemy should enter it along with the flying Romans, posted himself on the bridge, made head against the pursuers, and called on his countrymen to cut down the bridge between him and the city. Spurius Larcius, and Titus Herminius lent their aid in the heroic deed. When the bridge was nearly cut through, Cocles sent back his two companions, and singly maintained his post. At length the crash of the falling beams, and the shouts of his countrymen gave him to know that the deed was done; when calling on the god of the Tiber to receive him, he plunged into the stream, and, accoutered as he was, swam in safety to the shore, through the missile weapons of the enemy, which showered fast and thick around him.

Thus was the city saved from that sudden danger; but all its peril was not over. Porsenna not only retained possession of the Janiculum, but sending his army across the river in boats, pillaged the country, cut off all supplies, and reduced Rome to the utmost distress by famine. In this emergency, a noble youth, Caius Mucius, undertook to rid his country of this dangerous enemy. He made his way into the camp of Porsenna, and entered into the very praetorium, where he saw a person royally attired, and seated on a chair of state. Supposing this to be the king, Mucius sprung upon him, and stabbed him to the heart. He was immediately siezed, and led before Porsenna, whose secretary he had thus killed. There he acknowledged his deed, and told the king that his danger was by no means over. Porsenna threatened him with death by torture, unless he would divulge the plots by which his life was threatened. Mucius immediately stretched forth his right hand and thrust it into the fire of an altar which was burning before the king, saying, "Behold how much I regard your threats of torture." He held it in the flames till it was consumed, without a feature of his stern countenance indicating that he felt the pain. Porsenna, struck with his noble daring and contempt of suffering, commanded him to be set at liberty. Mucius then told him, in requital of his generosity, that he was only one of three hundred patrician youths who had vowed to kill Porsenna; and that he must prepare for their attempts, which would be not less daring than his own. From that time Mucius was called Scaevola, or the left-handed, because he had thus lost the use of his right hand.

B. C. 508.

Alarmed by the dangers which threatened him from foes so determined, Porsenna offered terms of peace to the Romans. A treaty was at length concluded, according to which Porsenna ceased to maintain the cause of the Tarquinian family; but demanded the restitution of all the lands which the Romans had at any time taken from the states of Etruria, and that twenty hostages, ten youths and ten maidens of the first houses, should be given up to him for security that the treaty would be faithfully observed. The legend relates that Clœlia, one of the hostages, escaping from the Etrurian camp, swam across the Tiber on horseback, amidst showers of darts from her baffled pursuers; but that the Romans, jealous of their reputation for good faith, sent her back to the camp of Porsenna. Not to be outdone in generosity, he gave to her and her female companions their freedom, and permitted her to take with her half of the youths; while she, with the delicacy of a Roman maiden, selected those only who were of tender years. The Romans then, at the final settlement of the treaty, sent as a present to Porsenna, an ivory throne and sceptre, a golden crown, and a triumphal robe, the offerings by which the Etruscan cities had once acknowledged the sovereignty of Tarquinius.

When Porsenna quitted Rome, he entered the Latian territories, and attacked Aricia, the chief town of Latium. The Aricians being aided by the other Latian cities, and also by the Cumans, under the command of Aristodemus, defeated the Etruscans in a great battle, and put a stop to their aggressions. The Romans received the fugitives from Porsenna's army, and treated them with great kindness; in requital for which Porsenna restored to them the lands which he had conquered beyond the Tiber.

Such is an outline of the poetical legends respecting the great war against Porsenna. It is, however, clear from other accounts and indications,[1] that Porsenna took the city, deprived it of one-third of its land, as was customary, imposed a tribute upon it, received the usual recognitions of sovereign authority, and even deprived the Romans of the use of metal in any other form than those employed in the purposes of agriculture, that they might not have it in their power to revolt. In this latter statement, we have again an incidental hint of the eastern origin and customs of the Etruscans; in proof of which, reference may be made to the way in which the Philistines tyrannized over the Israelites during one of their periods of conquest. (See Arnold's History of Rome.)

Tarquinius, as his last resource, now applied to the Latins, through the influence of his son-in-law Mamilius Octavius. He was the more encouraged to hope for success in consequence of a fierce war in which the Romans had been engaged with the Sabines, and by which they had been considerably weakened. For a time the Latins hesitated to provoke an encounter with Rome; and in the mean while the Sabine war continued to harass the republic. Valerius gained repeated victories over them, and some of the Sabines, wearied with fruitless hostilities, were anxious for peace. Attus Clausus, a Sabine chief of great power, came over to the Romans, became a Roman citizen, and took the name of Appius Claudius, on being admitted into the Patrician order. At length Valerius, after gaining another triumph, died, was buried at the public cost, and mourned by the matrons for a year.

War with the Latins.

The entreaties of Tarquinius, and the influence of Mamilius, had by this time prevailed among the Latins, and they prepared for a contest with Rome. Nor were the Romans unaware of the approaching struggle; and that it might be full and final, an opportunity was given on both sides for the dissolution of intermarriages, and such other ties as had been mutually contracted by the two nations. The Romans were determined to meet the decisive struggle as it ought to be met. They created a new magistrate, called a Dictator, to whom was entrusted for a period uncontrolled dominion. He was Master of the people; and he chose to be his second in command another officer, whom he named Master of the knights. The dictator was Aulus Postumius; the master of the horse Titus Æbutius. With these were joined in command the most distinguished Romans who had already signalized themselves in war. On the side of the Latins were Mamilius, and the whole of the exiled Tarquinian family, resolved to regain their sway, or perish in the attempt. The two armies met at the lake Regillus. The dictator and the banished king encountered hand to hand, but were parted by their followers. Mamilius and Æbutius were likewise separated, after the infliction of mutual wounds. Marcus Valerius fell while rushing into the throng of the fight against Sextus Tarquinius. The exiled princes bore down or put to flight all opposed to them, till the dictator himself, assailing indiscriminately the pursuers and the pursued, turned the tide of battle, and forced his way even into the enemy's camp. In this battle fell the two sons of Tarquinius, Mamilius, and the chief of the Roman warriors who had been the means of gaining their country's liberty; but the victory was complete. Tarquinius retired to Cumae, where he died, and the Romans were left to enjoy the victory, so gloriously yet dearly purchased.

Thus terminate the poetic legends respecting the wars waged between the Romans and the banished Tarquinii; and while it must be evident that a great deal of imaginative embellishments have been added to and intermingled with the course of the actual events, still there is enough of verisimilitude in them to give them currency, as at least a very spirit-stirring representation of what might have occurred. Besides, the effect produced on the Roman character by these poetic lays can scarcely be over-estimated, in stirring them up to that stern, unyielding courage, that unswerving energy of will, and that boundless ambition and confidence in the fortunes of Rome, which gained for them the empire of the world. While, therefore, we admit that it is impossible to state how much of fiction has been introduced into the narrative of these events, we see no reason to discredit the general truth of the history. The pride of the Roman historians concurred with the imagination of the poets, in maintaining to the utmost the glory of Rome; yet even from what they have agreed to record, we may arrive at conclusions somewhat different from those which they were anxious to establish. Rome was undoubtedly taken by Porsenna; and within twelve years after the expulsion of the last king, the Romans had lost all their territory on the Etruscan side of the Tiber, and all their dominion over Latium.

The principles of political liberty had also been severely shaken. It is plain that the Tarquinian family attempted to render the crown hereditary; and availed themselves of the jealousy between the patrician populus and the plebeian commonalty, to deprive each of their rights, and tyrannize over both. A junction enabled the nation to expel its tyrant; but the contest cost Rome her independence for a few years, and the loss of all her previous acquisitions. The defeat of the Etruscan army at Aricia enabled the Romans to recover their independence, but left them reduced almost within their original limits immediately around the city. The liberties of the commonalty were in danger in another manner, and from a different foe. Instead of a period of peace in the enjoyment of their recovered freedom after the decisive battle of Regillus, we find dissensions of the most serious kind arising almost immediately between the patricians and the plebeians. As these contests form a very important part of Roman history, especially in a constitutional point of view, and have been much misunderstood, it is necessary to offer a few remarks on their origin and nature.

It was the policy of Tarquinius to depress the growing power of the commons *(plebs)* as much as possible, that he might the better succeed in his ambitious designs. In this the patricians *(populus)* injudiciously joined him; and all the wise laws of Servius were repealed, or allowed to fall into desuetude. Additional enactments against debtors were framed, and every step was taken to reduce the plebeians to a condition little better than slavery. The wars arising out of the expulsion of the Tarquinian family blended for a time the interests of both classes, by the pressure of a common danger; but no sooner was this pressure removed, than the patricians resumed the oppression to which they had been too much accustomed, and were too prone. Again were the comitia centuriata allowed to fall into neglect, while in the senate, and in the comitia curiata, where they possessed exclusive power, the patricians enacted new laws against debtors, by which the plebeians were grievously oppressed.

The plebeians being composed generally of the population sprung from conquered cities, and admitted to settle at Rome in the enjoyment of personal freedom, were chiefly occupied in the culture of the public lands, or the lands held by patrician families. The loss of territory sustained by Rome in the Etruscan wars, deprived great numbers of the plebeians of their property and employment. Being reduced to poverty, they were compelled to borrow money from the patricians, whose lands lay chiefly within the Ager Romanus, and were not lost, and who also were alone permitted to enjoy the profits of commerce.[1] By the Roman law of debtor and creditor, when a man borrowed money, and his poverty continued, so that he became insolvent, there were but two resources to which he could betake himself. He might sell himself to his creditor, on the condition, that at the expiration of a stated term, if he did not discharge the debt, he should become the slave of his creditor. This was called the entering into a *nexum*, and the person entering into this conditional sale of himself was called a *nexus*. When the day came, the creditor claimed possession, the magistrates awarded it; and the debtor, his family, and all that belonged to him, passed into the power of the creditor as slaves, and were termed *addicti*. If, on the other hand, a man were unwilling thus to sell himself and family, and resolved to meet in his own person the consequences of his debt, the danger thus incurred was much greater. If he failed to pay, and could neither himself give security, nor obtain any person to give it for him, he might be thrown into a dungeon, loaded with chains, and half starved for sixty days. If during that time he refused to come to any terms with his creditor, he might be again brought to the market place, and the amount of his debt stated, to see whether any person would yet become security for him. On the third day, if no friend appeared, he might be put to death, or sold for a slave beyond the Tiber; nay, if there were more creditors than one, they might actually hew his body in pieces, and divide it among them; and whether a creditor cut off a greater or smaller piece than in due proportion to the debt, he incurred no penalty.

---

[1] See Niebuhr, vol. i. pp. 571, *et seq.*

B. C. 493.

In this manner vast numbers of the commonalty were reduced to the utmost wretchedness; and instead of the influence which they had been promised by the Servian constitution, they were in a worse condition than the veriest slaves. The old Roman populus, the patricians and their clients, had engrossed all the wealth and power of the community, and formed the government into an exclusive aristocracy. Great numbers of the plebeians were *nexi*, though not yet *addicti;* and in this condition felt themselves trembling on the brink of utter ruin. Driven to despair by their distress, the commons resolved that they would no longer endure their misery and degradation. Such of them as were in the city seized upon and began to fortify the Aventine hill, their own quarter; those who were at the time in the field, deserted their generals, marched to a hill on the north bank of the Anio, beyond the limits of the Ager Romanus, and within that of the Crustuminian tribe. There they established themselves, and proposed to found a new city. The patricians, perceiving the ruin that must fall upon Rome if thus deserted by the great body of the commons, entered into negociations with them for a return. Their demands were not extravagant. They required a general cancelling of the obligations of insolvent debtors, *(nexi)*, and the release of those who in default of payment had been assigned to the power of their creditors, *(addicti)*. They further stipulated, that two of their own body should be acknowledged as their public protectors, and that the persons of these two should be held sacred and inviolable. To these terms the patricians agreed; a solemn treaty was concluded; the two protectors of the commons were chosen, and called Tribunes, and the commons returned to Rome. The spot where this treaty had been concluded was enclosed, and consecrated to Jupiter, and received the name of the Sacred Hill.

This event was almost of equal importance with the expulsion of the kings and the abolition of the monarchical power. It laid the foundation of the liberties which the body of Roman citizens subsequently enjoyed; and by giving them legal rights and legal protectors, converted into legal contests what might otherwise have rent the state asunder. But at the same time it gave to the tribunate, in the inviolability of the persons of those who held it, the means of acquiring an unlimited power in the state, such as might and did lead to ultimate despotism.

The termination in an amicable manner of these feuds was greatly promoted by the fact, that the state was then at war with the Æqui and Volsci, two nations of Oscan race, whose lands lay south from Rome. It was no time for protracted civil broils when the country was ravaged, and the city itself threatened by such dangerous neighbours. To the same necessity may be traced the alliance with the Latin states, formed in the consulship of Spurius Cassius, on terms of perfect equality; and seven years afterwards by the same Spurius Cassius, with the Hernicians, on similar terms. These leagues were of the utmost importance to Rome, both as restoring to her the power which she had lost after the expulsion of the kings, and that too on a more equitable and therefore more permanent basis, and in commencing that thoroughly incorporating and blending system which afterwards converted all the inhabitants of Italy into Roman citizens, and thus consolidating her growth, confirmed her power.

Agrarian law.
B. C. 486.

A measure of equal justice, and not less importance, was also attempted by Spurius Cassius, the passing of which would have established the frame of Roman liberties on a secure foundation. This was an Agrarian law. The nature of the Agrarian laws, proposed from time to time at Rome, and always the cause of bitter contests between the patricians and plebeians, was never accurately known till it was explained by Niebuhr.[1] From him we learn, that when a new territory was gained in war, by the third being taken from the conquered people, part of it was left unenclosed for pasture, and the cultivated parts were either divided among the new citizens who had not previously received any allotment, or left to be occupied by certain individuals, who were required to pay a tithe of the produce to the state. The persons thus allowed to occupy these new acquisitions were generally members of powerful patrician families; and, although tenants at will of the state, they were actual proprietors with respect to the other citizens. When a number of new citizens had been added to the state, it was consistent with the whole polity of Rome to allot them lands: but in order to do so it would be necessary for the state to resume its property from its tenants at will, and divide it among the new citizens; for it was equally a matter of strict justice and sound policy to unite by permanent ties to the state those men by whose blood its victories were gained, and could alone be preserved. To this the occupiers would by no means consent; and thus the public land was wholly unprofitable to the commons, though they had been largely instrumental in conquering it for Rome.

The Agrarian law proposed by Spurius Cassius had for its object the division of a certain proportion of the public land; while from the occupiers of the remainder he intended to demand the regular payment of the tithe, which had been greatly neglected. His colleague, Proculus Virginius, headed the more aristocratical party of the patrician body in opposing the passing of this law, kept it in abeyance, if not uncarried, till the termination of his consulship, and then accused him before the comitia curiata of having treasonably conspired to make himself king, and for that purpose seeking to ingratiate himself with the commons. He was sentenced to die as a traitor, and was scourged and beheaded, and his house razed to the ground. Such was the fate of the first proposer of an Agrarian law; a topic equally detested by the Roman aristocracy, misinterpreted by the historians, and misunderstood by the moderns, yet a measure of strict justice and sound policy, and sufficiently intelligible when fairly stated.

B. C. 481

The contests between the patricians and the plebeians still continued; but the plebeians had now obtained the means of insuring ultimate success, though for a time defeated and overborne. They refused to serve as soldiers in the wars with which the state was still harassed, and their tribunes protected them in this refusal, till the consuls held their enrolment without the city, where their power was unlimited. At length the patricians consented that one of the consuls should be chosen by the plebeians in their centuries, the other by themselves, as usual, in their curiæ. This was a considerable advantage obtained by the plebeians; and they requited it by gaining a victory over the enemy.

For seven successive consulships the family of the Fabii had been elected, and had headed the patrician party. At length they resolved to conciliate the commons, and thereby incurred the hatred of their own order. Feeling them-

Roman History.

selves thus distrusted, and incapable of serving their country in council, they resolved to emigrate in a body, and establish themselves on one of the outposts of the Roman territory, to be a defence against aggression from that quarter. They settled on the Cremera, in Etruria; but about two years afterwards the Veientians surprised them, put them all to the sword, and destroyed their settlement. Three hundred of the Fabian house are said to have perished by this disastrous event.

B.C. 470.

In a short time afterwards new contests arose; the plebeians seized the Capitol; and the patricians were obliged to yield to the passing of the Publilian law, by which it was enacted, that the tribunes should thenceforth be chosen by the votes of the commons in their tribes, and not by those of the whole people in their centuries. They could now elect their tribunes freely; and they had formerly obtained the right of discussing all national questions in their own assembly. Had it been possible, when this great step was gained, for the two parties to have laid aside their contention, and regarded each other as truly brethren and fellow-citizens, instead of rivals, those rankling animosities might have been altogether allayed, which terminated only in the destruction of the republic, and the establishment of an imperial dominion, which was in fact a military despotism, so frequently the consummation of civil dissensions and revolutionary contests.

The wars between the Romans and the Æquians and Volscians still continued without any marked success on either side, internal feuds preventing Rome from exerting her whole strength; nay, at times inducing the army to suffer itself to be beaten, out of dislike to its patrician general. During these wars, some events of a striking character are said to have occurred, which seem to have formed the subject of popular poems, and have in that form been admitted into regular history. The story of Caius Marcius Coriolanus is the most brilliant of these warlike legends. He is said to have contributed mainly by his great personal valour to the capture of Corioli, and the defeat of a Volscian army assembled for its aid, on the same day. For this gallant exploit he received the name of Coriolanus. Soon afterwards, during a scarcity at Rome, he opposed the distribution of a supply of provisions sent by the king of Sicily, unless the plebeians would consent to forego the privileges they had so hardly won. For this he was tried in the comitia tributa and banished. He immediately joined the Volscians, and by his military skill and renown, at once defeated and appalled the Romans, till having taken almost all their subject cities, he advanced at the head of the Volscian army against Rome itself. In vain did embassies of his former friends entreat him to spare his country; he remained inexorable. At length a band of Roman ladies, headed by the mother and wife of Coriolanus, proceeded to his tent, where the lofty remonstrances of his mother were more powerful than all the arms of Rome. Coriolanus granted her request, at the same time exclaiming, "O mother, thou hast saved Rome, but lost thy son." Some accounts state, that he was soon afterwards killed by the Volscians in a tumult; others, that he lived to an advanced age among that people, often towards the close of his life exclaiming, "How miserable is the state of an old man in banishment!"

Another well-known and spirit-stirring legend of the Volscians is that of the dictator Cincinnatus. His son, Cæso Quinctius, had been banished on account of his violent abuse of the tribunes during some of the numerous contests between the patricians and the plebeians; and he had retired to his own patrimony, aloof from popular tumults. The successes of the Æqui and Volsci at length rendered the appointment of a dictator necessary, especially for the rescue of the consul and his army, who were surrounded by the enemy and blockaded in their camp. The dictator laid aside his rural habiliments, assumed the ensigns of absolute power, levied a new army, marched all night to bring to the consul Minucius the necessary succour, and before morning had surrounded the enemy's army, and reduced it to a condition exactly similar to that in which the Romans had been. The baffled Æqui were glad to submit to the victor's terms; and returning in triumph to Rome, he laid down his dictatorial power, after having held it only fourteen days.

Roman History.

About the same time, Rome was engaged in a war which ultimately led to consequences of the utmost importance. This was the war with Veii, at that time the most powerful city of Etruria, and distant only about ten miles from Rome. There had been peace between Rome and Etruria from the days of Porsenna; and the Etruscans had even supplied Rome with grain in a time of great scarcity, and when no other neighbouring state would grant any relief. A contest at length arose, which led to a war of nine years' duration, and a peace of forty years. This peace was concluded in the year of Rome 280.

B.C. 47

The intestine feuds between the patricians and the plebeians still continued with unabated animosity. Occasionally one of the consuls favoured the plebeians, and proposed some mitigation of their suffering, or increase of their privileges, but generally with little success. The Agrarian law, proposed by Spurius Cassius, continued to be the main demand of the commons and their supporters; but its passing was constantly either directly prevented or evaded. But at last the commons became convinced that they need hope for no complete redress of their grievances, until they should have previously secured the establishment of some constitutional principle, from which equal justice would of necessity, and from its very nature, flow. Accordingly Caius Terentilius Harsa, one of the tribunes, proposed a law for a complete reform of the existing state of things. Its purport was, that ten commissioners should be chosen, five by the patricians, and five by the commons, to draw up a constitution, which should define all points of constitutional, civil, and criminal law; and should thus determine, on just and fixed principles, all the political, social, and civil relations of all orders of the Roman people. The question of passing the Terentilian law, was now the subject of contention in Rome; and the patricians seem to have endeavoured to prevent it chiefly by interruptions to the proceedings of the popular assemblies, caused by the violence of the young patricians. In consequence of these interruptions, the commons carried the Icilian law, by which a tribune was empowered to impeach before the commons in their own assembly (the *comitia tributa*), any patrician who should interrupt him when discussing public measures, and might require him to give security for his appearance, on the penalty of death and confiscation of his goods, if he should refuse to give such security. This law gave to the plebeian assembly jurisdiction over a patrician, and thus placed in their hands, not only the means of defence, but of retribution or revenge. The banishment of Caeso Quinctius, and perhaps also of Coriolanus, were the consequences of the Terentilian law; but no dependence can be placed upon the dates given to these perhaps legendary lays.

B.C. 461

Three commissioners were at length sent to Greece, to collect from the Greek states, such notices of their laws and constitutions as might be serviceable to the Romans. After the absence of a year they returned; and the commons finding it in vain to insist upon five of their own body forming part of the revisers of the law, yielded the point, and ten of the most distinguished of the patrician and senatorial body were chosen to form an entirely new and complete code of laws, by which the state should be governed. They were named decemviri, and during their office they were to supersede every other magistrate; and each in his turn was to administer the government for a day, till they should complete their legislative labours.

B.C. 451

After the careful deliberations of a few months, the result was laid before the people, in the form of ten tables, fully

B.C. 450.

written out, and exhibited in a conspicuous place where all might read them. Various amendments were proposed, and the ten tables again laid before the senate, the curiæ, and the centuries, and having received the sanction of both orders of the state, were received and recognized as the very fountain of all laws, public and private, to use the expression of Livy. Nothing but fragments of these laws, afterwards known by the name of the Laws of the Twelve Tables, have been preserved to us; and even of these fragments, we cannot refer to more than those which relate to constitutional law, the origin and course of which we have been attempting to state and trace.[1]

Of these the most important which remain are the following. 1. That there should be an appeal to the people from the sentence of every magistrate. 2. That all capital trials should be conducted before the comitia centuriata. 3. That *privilegia*, or acts of pains and penalties against an individual, should be unlawful. 4. That the last decision of the people should supersede all former decisions on the same subject. 5. That the debtor whose person and property were pledged to his creditor, *nexus*, and he who remained the free master of both, *solutus*, should be equal in the sight of the law. 6. A sixth enactment, which unfortunately left matter for a grievance, and for future contentions, ordained, that there should be no legal marriages between the patricians and the plebeians; and that, if a patrician married the daughter of a plebeian, his children should follow the condition of their mother, should not be subject to the paternal law like his legitimate children, and should not inherit his property if he died intestate.

By these laws the privileges and rights of the commons had, in certain points, been greatly promoted, and in many others secured on the firm basis of national laws. But not only were subjects of great importance left unsettled on any equal foundation; these very laws, and the liberties of the entire community, were destined to encounter another peril of a formidable nature. The decemvirs had conducted matters so much to the satisfaction of the community, that when, at the expiration of their year, they requested a renewal of their office, on the ground that they had still two more tables to form, in order to complete their task, they were permitted to resume their powers without opposition. Appius Claudius, an old enemy of the commons, was one of the decemvirs, and was retained among them on their re-appointment. The possession of uncontrolled, irresponsible power, now began to display its usual consequences. The decemviri seemed resolved to change the government of Rome into a complete oligarchy, consisting of a council of ten, whose power should be absolutely supreme in every thing. They arrogated the right of superseding all other magistracies; and at the conclusion of their second year they shewed no intention of resigning their offices, or of appointing their successors. Popular liberty seemed on the point of being finally overthrown, just when its establishment on a secure basis had been fondly anticipated.

Matters had nearly arrived at a crisis when a war arose, the Sabines and Æqui having united their forces, and being desirous to avail themselves of the contentions by which Rome was weakened. The combined forces ravaged the left bank of the Tiber, and the Æqui encamped on Algidus and pillaged the country around Tusculum. The decemvirs assembled the senate, obtained their authority to raise an army, at the head of which they placed three of their number, and sent it against the Sabines. Another was raised and sent against the Æqui, while Appius Claudius remained at Rome to provide for the safety of the city, and for the maintenance of the power of the decemvirs. Both armies suffered themselves to be defeated, and retired nearer to the city, dissatisfied rather than discomfited.

Meanwhile Appius chanced to see a beautiful maiden named Virginia, daughter of Lucius Virginius, a centurion in the army sent against the Æqui. The maiden had been betrothed to L. Icilius, one of the tribunes, and the author of the law known by his name. Her beauty inflamed the passions of the licentious Appius, and he caused one of his clients, M. Claudius, to seize her as his slave, intending, in this manner, to get the person of the damsel within his power. Intelligence was immediately sent to the camp to Virginius, who, obtaining leave of absence, hastened to Rome to protect his daughter. But in vain did he claim his daughter, in vain appeal to the sympathy of the people, in vain address himself to the better mind of Appius. The decemvir, blind to every thing but the beauty of Virginia, and deaf to all but the impulse of his own passion, passed sentence assigning the maiden to Claudius. Upon this Virginius, snatching up a butcher's knife, exclaimed, "This is the only way left, my child, to keep thee free and unstained!" and plunged it to her heart; then turning to Appius, he cried, "On thee, and on thy head, be the curse of this innocent blood!" Appius ordered him to be seized, but in vain. Waving aloft the bloody knife, he burst through the multitude, flew to the gates, mounted a horse, and spurred headlong to the camp near Tusculum.

The wild and frantic aspect of Virginius, his attire stained with blood, and the bloody knife still held convulsively in his grasp, instantly drew a crowd of the soldiery around him. In brief but burning terms he told his tale, and called aloud for vengeance. One thrilling sentiment of sympathetic indignation filled every bosom; they called to arms, plucked up their standards, and marching to Rome, seized on the Aventine. The army near Fidenæ caught a similar spirit, having received information of the bloody tragedy from Icilius. They likewise threw off the authority of their commanders, chose military tribunes to lead them, and hastening to Rome, joined their brethren on the Aventine Hill.

In the city all was tumult and terror. The decemvirs were unable to make head against the excited multitude, and the senate itself felt its power ineffectual to allay the tempest. They began to treat with the people and the army, yet with dilatoriness, hoping the ferment would abate, and they might still retain their power. But the people were in earnest. Leaving a strong body to defend the Aventine for the present, they marched in military array through the city, and once more posted themselves on the sacred mount *(Mons Sacer,)* followed by vast numbers of the plebeian party, men, women, and children. Then were the patricians compelled to yield, and the decemvirs resigned. The plebeians obtained also the restoration of the tribuneship and of the right of appeal, with a full indemnity for the authors of the secession. The commons then returned to Rome, and re-occupied the Aventine; but along with it the Capitol also, as security that the terms of peace would be duly kept. The decemvirate was finally abolished, and the consulship restored; with this additional provision, that whereas formerly one had been appointed by the patrician curiæ, both were now chosen in the centuries. B.C. 447.

The new consuls were L. Valerius and M. Horatius, men who had shewn themselves to be favourable to the people. They wisely endeavoured to unite the two orders of the state on terms of perfect equality. A law proposed and passed by Valerius, formally acknowledged the commons of Rome to be the Roman people; a plebiscitum, or decree of the commons, was to be binding on the whole people; *quod tributim plebes jussisset, populum teneret.*[2] Such a popular decree, however, would not have passed into effect without the sanction of the senate, and of the curiæ; but it was a mighty stride in advance towards the obtaining of a recognized and legal equality between the two great orders of the state. B.C. 446.

---

[1] For an admirable view of these laws, see Arnold, vol. i. p. 253, *et seq.*

[2] Livy, iii. 55.

Laws were also passed, rendering every magistracy open to individuals of either order, the patricians to the tribunate as well as the commons to the consulship; and there seemed to be now a complete union of all parties in the state, with the exception of one point, the law prohibiting intermarriages between the patricians and the commons.

A re-action, however, took place, and the patricians had sufficient influence to prevent the new constitution from coming into operation. No plebeian consul was elected; and all the military tribunes, six in number, were chosen B. C. 445. from patrician houses. Another struggle took place; the tribune Canuleius proposed a law to repeal the prohibition of intermarriages between the two orders; and after a temporary secession to the Janiculum, this law was carried. Still the plebeians were not content without the consulship being rendered accessible to them; but this they were not yet able to obtain.

A new patrician magistracy was next appointed, which acquired powers not probably expected, or at first intended. B. C. 441. This was the Censorship, the main duty of which had at first been limited to taking the census of the people; but which, from the office of superintending the public morals with which it was entrusted, derived the power of reducing any dangerous citizen to insignificance, by degrading him from his rank and order. The commons had now acquired full security for their persons and their property; and while ambitious individuals would continue to be desirous of additional powers and privileges, the great body of the community felt little interest in their personal intrigues, and the state began to enjoy a period of comparative internal repose. The people had now learned the secret of their own strength, and how to make it available. For not long afterwards we find them aiding the senate when the consuls appeared inclined to disobey its authority, thus asserting their supreme power, and also refusing to permit the enrolment of soldiers for the Veientine war, unless the question of war were first submitted to the comitia centuriata.

The war with the Æqui and Volsci was again renewed, but was now waged by the united force of the republic, and with corresponding success. Several victories were gained and towns taken. Treaties were formed on favourable terms with the Latins and the Hernici, and Rome again began to extend her boundaries as she had done in the days of her kings. Her attention was now turned to the right bank of the Tiber, the peace with Veii being near its termination.

Between Rome and Veii a keen rivalship had long existed; and as the truce approached its close, both nations prepared for a strife which both intended to be final. The taking of Anxur from the Volsci, enabled the Romans to B. C. 404. send the greater part of their army against Veii. Several battles were fought, in which the Romans were generally successful, and Veii itself was invested. For some time it was rather a blockade than a siege; and when the Romans attempted a complete circumvallation, the Veientians, aided by some of the neighbouring states, stormed one of the Roman camps, and broke up the siege. Again was the city invested by the Roman armies, and again were those armies so severely worsted by the assistance of the Faliscans and Capenatians, that it was deemed necessary to appoint the celebrated Marcus Furius Camillus to the dictatorship.

Immediately upon his taking the command, the war began to assume a different aspect. A close siege was formed, and pressed with vigour; all attempts from without to raise it were defeated; all sallies from within repelled with great loss. The poetical legends connected with the fall of Veii, mention several prodigies that portended the approaching doom of the one or the other of the belligerent nations. The supernatural swell of the Alban lake, and the formation of a tunnel, by which its waters were drained off, and directed into the fields of the circumjacent country, was one romantic episode of this poetic lay. The stratagem by which the city was taken, a mine carried underneath the walls, and opening into the precincts of the temple of Juno, by which the Roman soldiers were enabled to burst from the earth in the very heart of the city, rush to the gates, and open them for the admission of their countrymen, while the general himself, issuing from the same subterranean passage, finished a sacrifice to Juno, which the priest had declared to be the omen of victory, certainly bears more the appearance of poetic fiction than of historic reality. Veii, the rival of Rome, was taken, and the greater part of the districts, formerly subject to the Veientians, added to the Roman dominions. Capena and Falerii followed its fate, and the whole valley of the Tiber, on both banks, formed now the natural extent of the territories acknowledging the sway of the seven-hilled city.

More important to the future glory of Rome, than the territory gained by the conquest of Veii, was the new principle in the organization of her armies to which the siege of that city gave rise. In order to insure the destruction of Veii, it was determined to surround it completely, and prevent it from receiving any supplies of men or provisions, either by summer or winter. This rendered it necessary that the beseiging army should continue its operations during winter, which was a measure never previously adopted. But as the soldiers were, in general, cultivators of land, and supported themselves by the produce of their own industry, without pay from the state, it was necessary to give them pay if their services were to be required permanently in the field.[1] This could be done only by the patrician holders of public land paying fairly their tithe into the public funds, besides bearing their due share of the public taxes. To this they consented, in order to secure the overthrow of their rival. Still the heaviest burden, and the greatest share of the danger fell on the commons; and in order to procure their consent, the election of military tribunes out of their order was at length sanctioned by law. Rome had now nearly acquired that formidable character in which she soon afterwards appeared to terrify and subdue the world; a military republic, where every citizen was, or might be, a soldier, and with a standing army inured to war and conquest.

Camillus, the conqueror of Veii, and the most distinguished man of his time, was accused of having secretly appropriated to his own use a portion of the plunder of that city. Whether he had been really guilty of so mean an action, or whether the accusation was prompted by envy of his glory, dislike of his haughtiness, or dread of his power, cannot be determined; but seeing the probability that he would not be acquitted, he went into voluntary exile to Ardea; and as he passed through the gates he is said to have turned, and invoked the gods, that if he were driven unjustly into exile, some grievous calamity might fall upon his ungrateful countrymen, and force them to feel his want, and to be glad to recall him to their rescue. Such a calamity was at hand, and ready to burst on the devoted city.

The Gauls had some time previously crossed the Alps, gained possession of the plains of the Po, penetrated the passes of the Apennines, and were advancing into central Italy. It is probable that the report of their approach was what prevented a union of the Etruscan cities when Veii was besieged by Rome. The Romans having accomplished their object, became also alarmed at the rumour of the advance of this terrible foe, and sent some of their citizens into Etruria to observe their movements, or at least obtain accurate intelligence. They arrived at Clusium just as it was beset by the Gauls. The Roman deputies joined the citizens in a sally, and one of them slew a Gaulish chief, and was recognized as a Roman while he was stripping off the spoil. The Gauls sent to Rome to demand the aggressors to be given up to them, as there had been no war declared between the Romans and the Gauls. The Romans refused to yield up their brave countrymen to torture and death; and the Gauls, finding their demands rejected, broke up in haste from Clusium, and marched away, shouting "to Rome, to Rome."

---

[1] Livy, iv. 59, 60.

The Roman army had marched towards the Etrurian frontier, expecting to meet the enemy at some distance from the city; but the Gauls had crossed the Tiber considerably higher up, and were proceeding along its left bank towards Rome. Upon receiving this intelligence, the consuls hastened back to the city, crossed the river, and marched rapidly against the enemy. The Romans had scarcely time to assume a hasty position on the banks of the Alia, where, through a deep bed, that slight stream joins the Tiber. The Gauls at the very beginning of the battle, turned the right flank of the enemy, drove it back in confusion on the main
B C. 388. body, and rushing impetuously in their victorious career, hurled the broken mass headlong into the river. The rout was total, the slaughter great. Many were drowned, and many more slain by the Gaulish javelins, while attempting to swim across the river; those who succeeded fled to Veii, and there sought an ignoble safety. Others fled to Rome, carrying the tidings of their utter discomfiture; and thence continued their flight to Veii, despairing of being able to save Rome. The Capitol alone was garrisoned by a devoted few, who were resolved to defend this last bulwark of their country, or perish in its ruins.

The city was left open and undefended, but it was on the third day after the battle that the Gauls entered it. In the interval, the great body of the Roman citizens had abandoned their homes, and fled for refuge to the neighbouring cities, carrying the most sacred of their images and relics to Caere, and leaving those which they could not remove deeply buried in a secret retreat. But some of the priests, and the aged patricians of the highest rank and dignity, could not endure the thought of quitting their native city, and dragging out the remainder of their feeble days in a foreign land. They solemnly devoted themselves and the Gauls to the infernal deities, and then seated themselves in the forum to wait their death, by which they hoped to draw down on the Gauls the vengeance of the gods. When the Gauls entered, all was silence in the forsaken city, nor did they see a human being till they reached the forum. There they beheld the majestic fathers of Rome, seated each on his ivory chair of office, and clad in his senatorial robes, unmoving, silent, awful impersonations of sublime despair. The Gauls gazed on them with reverential respect, regarding them as more than mortal. At length one of the Gauls drew near to M. Papirius, and began to stroke gently his long white beard. Papirius, a priest of the highest rank and sanctity, indignant at the profane touch of the barbarian, struck him on the head with his ivory sceptre. The Gaul cut down the venerable man with his sword. The spell was broken; barbarian fury kindling at the sight of blood, rushed on its defenceless prey, and in an instant the vows of the aged senators were ratified in their blood.

After pillaging the forsaken city, the Gauls turned their attention to the Capitol; but being unable to scale the rock, were repulsed from the only access with considerable loss. They now changed their plan, made the city their head-quarters, continued the blockade of the Capitol, and spread devastation into the surrounding country. Meanwhile the Romans who had taken shelter at Veii, began to recover courage, and to seek to open a communication with the brave garrison in the Capitol. This was accomplished by a daring youth named Pontius Cominius, who swam across the Tiber and scaled the cliff during the night, and having explained to the garrison the state of affairs at Veii, returned as he came, undiscovered by the Gauls. But in the morning some traces of his exploit were seen by the besiegers, who concluded that if the cliff had been scaled by one, it might by more. They made the attempt, and the spot being thought inaccessible, and therefore left unguarded by the garrison, they had nearly reached the summit, when the sacred geese kept in the temple of Juno, hearing the unwonted sound at such an hour, made so much noise as to awaken M. Manlius, a young patrician, whose house was hard by the temple. He sprang up, seized his arms, called on his sleeping comrades, and ran to the edge of the cliff just as the head of a Gaul was appearing above it. Manlius rushed upon him, dashed the boss of his shield into his face, and tumbled him down the precipice. The falling Gaul bore down many of his countrymen along with him, and the rest, perceiving themselves discovered, and struck with terror, leapt, fell, or scrambled down the crags, and abandoned the attempt.

But though the Capitol was thus secured against direct force or surprise, it might be reduced by famine, and therefore the Gauls continued the siege. The brave garrison were reduced to the utmost extremities, but still continued the defence of their impregnable citadel, till the Gauls began to suffer scarcely inferior calamities, arising likewise from the want of food, aggravated by the unhealthiness of a Roman autumn. Great numbers daily perished; and the place where their bodies were burned was long afterwards known by the name of *Gallica busta*, or Gallic funeral piles. These calamities induced the Gauls to offer more reasonable terms, which the exhausted garrison was willing to accept. The demand was one thousand pounds of gold, on payment of which the Gauls agreed to depart from the Roman city and territories. It is also related that the Gauls had received intelligence of their own country being invaded by the Venetians, which increased their willingness to come to terms with Rome.

A truce was concluded; both parties met in the forum; and the military tribune, Q. Sulpicius, proceeded to weigh the stipulated sum. The Gauls fraudulently attempted to falsify the weights; and when Sulpicius complained, Brennus, the king of the Gauls, cast his heavy broadsword into the scale which contained the weights. The tribune asked what was meant by this action; and the haughty barbarian insultingly replied, "It means, woe to the vanquished." Having received this large ransom, the Gauls appear to have departed from central Italy, and returned to their own settlements on the regions in the valley of the Po, leaving the Romans to set about repairing, as they might, their sacked and desolated city.

The accounts which represent Camillus to have entered the forum at the moment when Brennus had uttered his insulting *Vae victis*, and to have ordered the gold to be taken away, saying, it was the custom of Romans to ransom their country with steel, not gold; to have driven the Gauls out of the city, and next day to have defeated them so totally that not a man was left alive to carry the tidings of their defeat to their countrymen; these accounts are manifestly parts of some poetical lays in honour of Camillus, the hero of his age and country. But they are too inconsistent with the more plain statements of other historians, and with the well known facts of the case in other respects, to receive any other than a poetic credence best suited to their poetic character.[1]

But when the first feelings of exulting triumph abated, and the Romans began to gaze around them on the scene of ruin and desolation, their hearts sunk within them, and they were on the point of yielding to the wretched dictates of cowardly despair. It had been previously proposed by the popular party, that a large body of the Roman citizens should at once migrate to Veii, and raise it to an equality with Rome in power and privileges. This destructive proposal was at the time successfully resisted by the more clear-sighted patricians; but now, when Rome was in ruins, the people few and dispirited, and Veii in a flourishing condition, its buildings better than even those of Rome had been, the proposal to quit the scene of devastation, and remove to one of comfort, was renewed and listened to with eagerness. It required all the authority of Camillus, enforced by that of the senate, and strengthened by every kind of assistance and encouragement that could be devised, to induce the Romans to remain, and undertake the heavy and almost hopeless task of rebuilding the ruined city of their fathers.

---

[1] See Niebuhr, vol. ii. p. 547, *et seq.*

Livy informs us, that while the senate were sitting in grave and final deliberation respecting the removal to Veii, or the rebuilding of Rome, the people at the same time standing in clusters about the forum eagerly debating the same subject, some cohorts, returning from relieving guards, chanced to pass through the forum, when a centurion in the comitium called aloud, " standard-bearer, plant your standard; here we shall best remain." The well-omened expression was seized upon by the senate, they rushed out, exclaiming with one voice, that " they accepted the omen;" the surrounding commons applauded and re-echoed the cry; and all, with one voice and one mind, agreed to abide by the will of the gods thus indicated, to raise from prostrate ruin, and maintain the destinies of their everlasting city. There is little doubt that Camillus planned this fortunate omen, and by his well-directed efforts in this point, not less than in war, gained the glorious designation of A NEW ROMULUS, FATHER OF HIS COUNTRY, AND SECOND FOUNDER OF ROME.

Progress of Constitutional Law.

Hitherto we have been led to trace the growth of Rome from the building of the thousand Romulean huts on the Palatine, till under the Etruscan dynasty of its kings it had extended its power in all directions, entered into treaties with transmarine nations, and raised at home structures of great magnitude and imperishable durability. We have seen it sink into comparative feebleness during the intestine wars by which it was torn immediately after the expulsion of its tyrant monarch; yet even then have we also seen noble proofs of that love of liberty, that strength of stern indomitable will, that irrepressible perseverance, and that lofty confidence in their own destinies, which conspired to render the proud citizens of Rome the conquerors of the world. Of even more importance is it to trace the growth of constitutional law, as it arose out of the struggles of one party which wished to engross and retain all civic rights and privileges, and the growing wealth, intelligence, and power of another, which gradually became more and more sensible of its rights, and more and more determined to obtain them. Even the most careless observer of these contests, and their fluctuations of success and disappointment, must have marked, that whatever either party gained by unconstitutional violence, was never to either a permanent gain; that any premature advance of popular liberty was almost instantly followed by a recoil, proving, that not the soundness of a principle, nor the truth and accuracy of a theory, but the substantial, the felt, the practical necessity of the measure, is the only sure foundation of any addition to, or change in, the institutions of a country; and that the natural and spontaneous adjustment of existing rights and institutions, which takes place wherever they are pervaded by the genial influence of a healthful vitality, is productive of a far greater and more lasting amount of true liberty, public and private, and of all that can promote real national welfare, than could ever be obtained or secured by those impetuously philanthropic legislators, who dream of creating a commonwealth in a day, as a magician would produce a palace by the utterance of some all-powerful spell.

To trace the growth of constitutional law as accurately as possible, we must revert to the earliest period of Rome, and endeavour to extricate from their fabulous envelopements the historical truths contained in what are now admitted to be poetic legends. By this process we may hope to obtain as rational and intelligible a view of the city, the people, and the constitution of Rome, as the preceding narrative is capable of affording. It has already been stated, that the various inhabitants of that district of Italy, in which Rome was built, were the Oscan, Pelasgian, and Etruscan. The Pelasgi appear to have settled chiefly along the coast of Italy, from which they drove back the original inhabitants, who were probably Oscans. In process of time the Oscans descended again in great force from the mountains, overpowered the Pelasgians, and reduced them to a species of servitude, allowing them however to remain as tillers of the land, and artificers. From this intermixture arose the people subsequently known by the name of Latins; combining the hardy and warlike habits of the Oscan mountaineers with the superior skill and civilization of the Pelasgi. This view may be regarded as confirmed by the fact, first pointed out by Niebuhr, that the words which relate to agriculture and the comparatively refined arts of life, in the Latin language, are closely allied to the same words in Greek, indicating the Pelasgian origin of both; while the Latin words pertaining to war and the chase are entirely alien from the Greek, and are in short of Oscan origin.[1] From this it may be inferred, that during the formation of the Latin language, the nation was composed of two races, the Oscan and the Pelasgian, of whom the Oscan held the chief sway. The two races being both accustomed to the simple patriarchal, or family form of rule, would have a natural tendency to blend together so as speedily to become one people. This seems to have been the condition in which they were, during the period when Rome is said to have been built.

Whether the traditionary founder of Rome was of Oscan or Pelasgian race, cannot be ascertained. The greater part of his followers appear to have been Pelasgian; and from them the settlement may have obtained its name, which was afterwards given to the legendary hero himself. One of the traditionary accounts of Romulus, represents him as having been sent in his youth to an Etruscan city, for the purpose of receiving instruction superior to what could be obtained in Latium. Were we receiving the narrative as that respecting a real person, we should ascribe to his Etrurian education the attention paid by Romulus to augury, and the other arts of divination, in which the Etruscans are known to have excelled. The tradition may however refer to some influential Etruscan leader, who may have joined the early founders of Rome, and contributed greatly to mould their religious institutions. This view is supported by the statement of some authors, that an Etruscan chief, named Lucumo, was an early ally of Romulus, and aided him in the Sabine war, in which he was killed. The term Lucumo, we know, was not a personal name, but one of rank and office common to the Etruscan chiefs, who were all Lucumones. This Lucumo may have been the Tuscan chief Caeles Vibenna, who is said to have settled on the Caelian hill, to which he gave his name.[2] If this be admitted, and we suppose the followers of this Etruscan Lucumo removed to Rome by the Roman founder, after the fall of their own chief, we have a very probable account of the origin of the third tribe of the Roman people, the Luceres, who, though admitted as an original tribe, were in some respects subordinate to the other two, the Ramnenses and Titienses, or Romans and Sabines. The Luceres may have been of a more mixed race than the other two tribes, and on that account somewhat less esteemed. It is indeed by no means improbable that the first inhabitants of Rome were composed of some of all the adjoining states, although the Oscans and Pelasgians were the most numerous.

---

[1] Niebuhr, vol. i. p. 83.

[2] Ibid. pp. 382, 383.

With regard to the Etruscans, we are of opinion that for a very peculiar reason, they could not have formed any considerable proportion of the inhabitants of Rome. We are inclined to hazard the conjecture, that the name Etruscan, as commonly used, is extremely deceptive, and leads almost invariably to error. The true name of the peculiar people generally called Etrusci, was, according to themselves, Rasena. It is constantly asserted that their language is totally unknown; and yet they are said to have occupied a very large portion of Italy, and to have been in constant and intimate intercourse with the nations inhabiting its other divisions. It is scarcely credible that not one word of confessedly a highly civilized people should have entered into the language of those nations with whom they held intercourse. But, if the body of the people called Etrusci were of Oscan, Umbrian, or even of Celtic origin, while the Rasena were merely a race of skilful and intelligent foreigners, who had, by force or policy, acquired the station of a ruling and a sacerdotal caste, their peculiar language might never be communicated to the body of the people whom they ruled, and so might perish when their power was broken and their caste destroyed.[1] The possibility that the Rasena were indeed a sacerdotal caste, similar to those of Egypt, India, and other oriental nations, perhaps also of the Celtic race, will scarcely be questioned by those who are acquainted with the history of the Brahmins and the Druids.[2]

atriarchal nciple.

Reverting to what has already been stated respecting the patriarchal form of rule common to the Oscan and Pelasgian races, we are furnished with an explanation of the central principle of all the Roman institutions. The form of government resulting from such a principle was necessarily monarchical, but could not be despotic. For, while the king ruled supremely over the nation at large, every head of a family ruled over his own household with uncontrolled sway, at once as its king and its priest.[3] But, in order to obtain the advantages of union, the families, houses, or gentes, formed themselves into bodies of *ten* each, called *curiæ*. Over each curia, one head of a House, or *gens*, held a sort of presidency, and received the name of *curio*. The union of ten curiæ formed a tribe. The union of the three tribes, the Ramnenses, or Romans strictly speaking and with reference to the inhabitants of the Palatine hill, the Titienses, or subjects of Titius, who were Sabines, and inhabited the Quirinal and Capitoline hills, and the Luceres, who were probably the original followers of the Etruscan Lucumo who aided Romulus, and settled at first on the Caelian hill, augmented by adventurers from neighbouring states, formed the Populus Romanus in the strict sense of that term. Thus the patriarchal principle pervaded the entire body politic, and gave to it all that was peculiar in its aspect and institutions.

P rons a Clients.

We must not, however, omit to mention, that within this external and public form of the body politic there was included another of a more private and personal character. As a state, tribes, curiæ, and houses were alone visible; but in each house there were necessarily members and dependents. The *members* connected by blood with the head of the house, or gens, were *Gentiles*, or as we might term them, *kinsmen*, and formed the free citizens of Rome: the *dependants*, who were not all, nor necessarily, blood relations, were called *clientes*, and might, with some modifications, be designated *clansmen*, belonging to the clan, but beneath the rank of the *duinne-wassal*, or gentlemen directly related to the chief. From this arose that more private or domestic division of the people into *patroni* and *clientes*. The patrons alone were recognised as citizens by the state, in their various aspects, as heads of houses, members of the curiæ, and of the tribes; and by them, and for them, were all laws made, with all which the clients had no connexion. The relationship in which the clients could alone be viewed was entirely of a private nature, subsisting exclusively between them and their patrons. The power of the patrons over the clients, on the other hand, would have been altogether despotic, but for the patriarchal element from which it sprung, and by which it was tempered. The client was regarded by the patron as to a certain extent a member of his family, owing to him indeed the most implicit obedience, but having the strongest claims upon him for protection, and even for some measure of paternal regard. The patron was bound to relieve the distress of his clients, to appear for them in court, to expound to them the law, civil and pontifical, and to allot them portions of land to cultivate and build upon, which, however, they held only as tenants at will. The clients on their part were bound to be obedient to their patron, to promote his honour, to pay whatsoever public fines might be imposed on him, to aid him jointly with the real members of his house, in bearing the public burdens of taxes, to contribute to the portioning of his daughters, and to ransom him or any member of his family who might fall into the hands of an enemy. If the client died without heirs, the patron succeeded to his property; and if the patron failed in discharging his duty to his clients, he was accounted infamous and accursed.

Tribes.

But the union of the three Tribes belongs to a subsequent period of the history. Although it seems sufficiently probable that the rudiments of the tribe called the Luceres, existed in the time of the founder of Rome, yet that tribe was not raised to a full equality with the other two till a later period. During the reigns of the first two kings of Rome, the nation presents a strictly twofold aspect, consisting of the two chief tribes, the Ramnenses and the Titienses. In each tribe the arrangements were precisely similar, ten houses constituting a curia, and ten curiæ a tribe, of which the heads of houses formed the senate, and the heads of the curiæ formed the chief senators. The great national council consisted thus of 200 senators, half Romans and half Sabines, or, laying aside the national designations, and retaining those of the tribes alone, half Ramnenses and half Titienses. The senate thus being wholly composed of heads of houses, its members were rightly named patres, and their order the patrician; but this patrician order comprehended at first the entire people, in consequence of the family-relationship, which, in fact or semblance, pervaded the whole community. Every head of a house was the judge and ruler of his house, both members and clients; the curia of ten houses governed the affairs of their collective body; and the senate of ten curiæ deliberated upon the affairs of the nation. In those early days, the assemblies of the people were merely assemblies of the patrician houses, who alone possessed the rights of full citizenship; and these assemblies were held in the valley between the Palatine and Capitoline hills, termed the Forum

---

[1] Niebuhr, vol. i. p. 122.

[2] If this view could be substantiated, it would explain many of the most difficult questions that arise respecting the Etruscans. It would at once account for the want of a community of interest between the Etruscan chiefs and the body of the people, which prevented the growth of any regularly consolidated power among them, caused those sudden transitions from strength to weakness, and led ultimately to the disappearing of the ruling caste, and the complete blending of the real people with the other Italian nations. For when the Rasena ceased to rule, having little, if any thing, in common with the body of their subjects, not even their language, they speedily ceased to have a separate existence; and the people, who were correctly designated Tyrrheni, or Tursceni, and were of Pelasgic origin, very soon blended with their more kindred races, as, indeed, the Luceres had done with the primitive Romans at an earlier period.

[3] See Niebuhr, vol. i. p. 306, *et seq.*; and Arnold's History of Rome, vol. i. p. 25, *et seq.*

Romanum, and said to have been the place where the comitia curiata were held from the time of Romulus.

At this time the body, afterwards known by the name of the plebs, or plebeians, had no existence, the entire population being composed of patrician houses, with their members and dependents, in other words, of patrons and clients, the patrons alone being full citizens, and known as the people. In a very short time a population of a different character began to appear, composed of strangers who came to settle in the country, and the inhabitants of conquered states brought forcibly to Rome, and obliged to unite to a certain extent with their conquerors. This population had, of course, no connexion with the houses, but only with the state politically. They could not become *members* of the houses; they were not *dependents* on them; and thus they came to form a body of an entirely new character, springing up in the midst of the privileged citizens. They were not permitted to intermarry with the houses, who were very tenacious of purity of blood; and thus they belonged to no house, no curia, and no tribe, consequently they had no share in the public government nor in the public property. Their own property in their native country might have been diminished, or altogether lost in that war by which they had been subdued, in consequence of the law by which a third part of a conquered nation's lands was seized by the conquerors; yet what the state might subsequently seize in war, even by their aid, did not become theirs, because they formed no integral part of the state as such, being *in* the state, but not *of* it. Such an inferior population, of a character, and occupying a position so anomalous, not slaves, yet not citizens, was the element from which arose the original plebs or commons of Rome.[1]

Luceres.

The only events recorded in the legend of Tullus Hostilius, to which any degree of credit can be attached, are those which refer to the Alban war and its consequences. It seems to be a fact, that at some indefinitely early period in the history of Rome, the honour of being head of the great confederacy of the thirty towns of Latium, which had belonged to Alba, was transferred to the former city. This has been ascribed to the reign of Tullus; and as no period to which it may with greater certainty be referred, can be pointed out, it may be regarded as an historical truth, accounted for in no unnatural manner by a national legend. The combat of the Horatii and the Curiatii appears to be chiefly a poetical episode, and one of a very high and spirit-stirring character, but may have had some foundation in fact. The death of Tullus is also legendary and imaginative. It seems to have been partly at least an Alban lay, from its indications of divine wrath falling upon Tullus on account of the desolate temples and deserted gods of the Alban mount. But the most important part of the narrative is that which records the reception into the state of the third tribe, the Luceres. In the legend, this is said to have taken place in consequence of the union of the Albans with the Roman people. There may be a considerable portion of truth in this statement, and it is perfectly consistent with the known facts of the case, as far as they bear upon the subject. The Luceres were held to be to a certain degree inferior to the other tribes, as was not unlikely to be the case with the descendants of a conquered people. All the patrician houses that traced their genealogy to the Albans belonged to the Luceres, such as the Julii, Quinctii, Servilii, Cælii, and several others of the most distinguished Roman houses. The explanation of the name Luceres cannot be clearly given. Some derive it from the Lucumo who is said to have settled on the Cælian hill, and to have given it his name. If he founded a small city for his followers, and give it his official name, as he gave the hill his personal, the name of the town might be Lucerum; and when the Albans were located on that hill, and in that town, and raised to the condition of a tribe, they might be called Luceres from their new abode, and in order to sink the remembrance of Alba.

Plebs.
Plebei

The most important event recorded in the period assigned to the reign of Ancus was the removal of the conquered Latins to Rome, and the apportioning to them of a settled residence on the Aventine hill.[2] This may be regarded as the origin of the Roman plebs, or commons, as distinguished from the patrician body, who were the true and original Populus Romanus. It cannot be too distinctly stated, nor too clearly and strongly remembered, that among the early Romans, the populus and the plebs were wholly and in every respect different. The populus was originally the whole body of the early inhabitants of Rome, both those of Romulian and those of Sabine origin. This body, consisting of senators or patres, curiæ, and houses, with their members and dependants, was completely aristocratic in its aspect, and tolerated no degrading intermixtures. The plebs were originally the conquered Latins, who were in a measure incorporated into the mass of the nation, by being removed to the Roman territories, placed on the Aventine hill, and permitted to farm the land of the state, which latter arrangement is said to have been made by Ancus. They retained their personal freedom, but could neither become members of houses, nor in general would submit to be dependants. They grew up, therefore, along with the populus, a free, but unprivileged, and too often an oppressed population; and though both despised, feared, and hated by the exclusive patrician populus, rapidly growing what they ultimately became, the real strength of Rome. Had it not been for the patriarchal principle pervading Rome, which caused the ties of kindred to be the only legitimate method of obtaining the full privileges of a citizen, these near residents might have been admitted at once, and all the subsequent fierce domestic broils might not have taken place; but without these contests the nation might never have been knit into such compact strength, nor have been led to the formation of such a body of wise and well-digested laws.

New
tors.

In the constitution of the Roman state, Tarquinius made at least one alteration concerning the true nature of which, authors are by no means agreed. Some say that he added an hundred members to the ancient senate, which till then had amounted to no more than two hundred. These new senators were called fathers of the lesser houses, *(patres minorum gentium;)* and the old senators fathers of the greater houses, *(patres majorum gentium.)* If this account were entitled to implicit credit, we should regard it as referring to the admission of the Luceres into the full enjoyment of the rights and honours of citizenship. Yet this seems to have taken place during the reign of Hostilius, when he brought the conquered Albans to Rome. Perhaps a portion of each statement may be true. The Albans and Latins may have been settled on the Cælian hill, and formed into a tribe by Tullus; but not raised to the senate till the accession of Tarquinius, who may have thought such a step necessary in order to secure the support of a large body of the state, his claims to the throne being so very questionable. It is true Niebuhr[1] hazards another very ingenious conjecture. He thinks that Tarquinius may have been himself one of the tribe of the Luceres, that Priscus may have been a name belonging to him, as one of a Priscan gens, or house, and that the legend of his Etruscan conquests and acknowledged sovereignity may have some connexion with the much more ancient tradition of the fabulous Tuscan hero, Tarchon, to which the name Tarquinius itself may allude. It is sufficiently evident, that there did exist at some remote period, an intimate intercourse between Rome and the Etrusci; and there appears to have been some connexion between this Etruscan influence and the tribe of the Luceres. What the exact nature and extent of this Etruscan intercourse and influence were, it seems a hopeless task to inquire, and it would be fruitless to indulge in framing conjectures.

---

[1] It may be added, though here we are anticipating the regular course of events, that the great proportion of the Roman commons were conquered Latins. Besides receiving grants of a portion of their former lands, to be held by them as tenants at the will of the state, they had also the Aventine hill assigned to such of them as removed to Rome. The Aventine was not included within the walls of the original city, so that these half-citizens became the suburban neighbours of Rome rather than its inhabitants, enjoying its protection, sharing heavily in its burdens, exposed to a full proportion of all its dangers, but excluded from all its political rights and privileges. From such a condition no wonder that future contentions arose.

[2] See Niebuhr, vol. i p. 355.

It is stated, that Tarquinius wished to add to the centuries of the Equites, established by Romulus, three new centuries, and to call them by his own name, and the names of his friends. In this intention he was opposed by the augur Attus Navius, who affirmed that what had been instituted with augury, could not be changed without it, and that the omens forbade any change. The king, in order to cast discredit on the art of the augur, asked him to divine whether what he was then thinking of could be done. The augur observed the omens, and answered that it could. "I was thinking," said the king, "whether you could cut this whetstone in two with a knife." Navius instantly took the whetstone, and cut it sheer asunder, to the amazement of the king. This proof of the augur's skill caused Tarquinius to desist from his intention to its full extent; and he merely added to each of the former centuries a second or latter century under the same name. In this legend may be contained an account of the opposition which Tarquinius experienced from the patrician body, when he purposed to raise a number of the most distinguished of the free citizens to the equestrian rank,—an opposition to which he was so far obliged to yield.[2]

It has been already stated, that the constitution of Rome[3] was founded on the patriarchal principle, as to its essential characteristic, while the numerical divisions of the government by tens were arbitrary, so far as can be traced. Every head of a house was an integral member of the state, as a free citizen; but there is no very manifest reason why houses should have been aggregated into *tens*, or curiæ, these into other *tens* forming the senate, or patres, of one hundred. But this division or rather aggregation having been adopted, it influenced all the arrangements of the body politic, both in peace and war. While there was but one people, the followers of Romulus, there was but one tribe, the Ramnenses, or, as some term it, the Ramnes, and the senate amounted to one hundred. Upon the junction of the Sabines, there were two tribes, the Titienses or Tities being added, and consequently the senate then numbered two hundred. The elevation of the third tribe, the Luceres, completed the number of curiæ, decuriæ, tribes, and senators, till thirty and three hundred became the ruling numbers in this division.

It is worth remarking, that, according to the statement of ancient authors, when Romulus formed the Pomœrium, including all that composed ancient Rome, his city merely contained one thousand wretched huts, clustered together on the Palatine hill. Now, if it could be shewn that the union of ten families formed a house, ten houses a curia, and ten curiæ the entire tribe, we should have the exact number of the first huts erected on the Palatine, and of the primitive mansions of the Roman fathers.

The army followed in its construction the numerical arrangement of the people. The earliest Roman legion could contain no more than the male inhabitants of Rome, which would be at that time only a thousand capable of bearing arms. As the senate was formed from the hundred chief men of the curiæ, so there were an hundred of the bravest selected from the curiæ to fight on horseback. Thus the equites, or knights, were at first equal in number with the senate, and equal in rank, as members of the curiæ, though not senators, because not the heads of the curiæ. When the senate was increased to three hundred, by the addition of the other two tribes, there were also three centuries or hundreds of knights, retaining the proportion. The legion would then consist of 3000 infantry, and 300 cavalry; and though in later periods the numbers of the infantry were increased, 300 continued to be the legitimate number of cavalry in a legion. Although the name remained, the numbers fluctuated according to the dictates of policy or necessity, so that when we read of a century, we are not to assume that an hundred is meant, and neither more nor less.

Servian Constitution.

Adopting recognised terms and divisions, Servius, in his endeavours to improve the constitution of Rome, divided the large body of unprivileged yet free citizens, the plebs, or true commons, into thirty tribes, according to the thirty curiæ of the senatorial patricians. Of these thirty tribes four were contained in the city itself, and the remaining twenty-six in the lands that had been added to the dominions of Rome by conquest. Each tribe was under the dominion of a magistrate of their own body, called a Tribunus. There were also judges appointed, three for each tribe, to determine private causes among the plebeian citizens. For the appointment of these official persons, and other matters connected with their own interests, the plebeians were empowered to hold their own meetings, called the comitia tributa. These were held on the *nundinæ*, or market days, when the country people came to Rome, and in the forum or market-place adjacent to the comitium, or meeting place of the patricians, but quite distinct from it. These comitia tributa were entirely plebeian, and at first referred only to the decision of disputes respecting private rights among the plebeians themselves. They were not convoked by the patricians, nor held under patrician auspices. They had nothing to do with national affairs as such, but were confined entirely to the private business of the plebeian order. Neither had the patricians at first any thing to do with this plebeian assembly: they formed no part of it, and had no authority over it. Yet, though thus distinct from the state in its original formation, it gave an organized form to the plebeian body, which soon proved its importance, as the very thews and sinews of the body politic, and therefore essential to its growth and strength.

Comitia Centuriata.

The institution of the comitia tributa, though at first of an entirely private character with reference to the state, tended to the formation of a new assembly, in which all the orders of the people were included, and arranged for the discussion of public affairs. It was not possible that the plebeian body could be so far organized as to have its own, magistracy, elected by itself in an assembly of its own, without producing an early necessity for its admission into the state; for organization both gives power, and the consciousness of power, in the body politic. The most natural occasion and mode of its admission, had a military origin and character, like most of the other Roman institutions. Though the patricians and plebeians remained completely distinct in their civic character, and in the time of peace, yet in the time of war they acted together in one great body, the army. The arrangements of the army were therefore those which led to their junction in another aspect, and were in that new aspect retained as much as possible. As the earliest principle of the structure of the Roman army was its division into centuries, so the same principle gave rise to an assembly of a new character, called the comitia centuriata, where the military principle predominated, and in which the whole population met. So much of a military character did this assembly at its origin bear, that it was not permitted to meet within the city, but in the Campus Martius, and it even bore the name of *exercitus urbanus*.

---

[1] Niebuhr, vol. i. pp. 376, 377.

[2] See Niebuhr, vol. i. pp. 360, 361.

[3] For a full view of the Servian constitution of Rome, see Niebuhr, vol. i. pp. 405–487. Arnold, vol. I. pp. 64–82.

Tarquinius is stated to have added, not three new centuries bearing new names, to the equestrians, for that was prevented by the augur Navius, but three new centuries, forming a second series, and retaining the designation of the first three. These three double centuries of the Ramnenses, Titienses, and Luceres, were now recognised as distinctly six privileged bodies of voters, *sex suffragia*, of the new assembly. To these, which contained all the members of the houses, there were added by Servius twelve new centuries of knights,formed from the richest members of the plebeian community, and continuing, like the centuries below them, to belong to the thirty tribes of the commons. There were thus eighteen centuries of the most noble and wealthy persons in the state, who enjoyed the privilege of serving in the army on horseback; known in their military character as the equites, and in their civil character as the equestrians, or, as we term them, the knights. Their distinction as an order was however posterior to their formation as the eighteen equestrian centuries in the comitia centuriata.

Classes.

Proceeding on the military principle, the next point was to organise the foot soldiers of the state. This was done chiefly with reference to the value of the armour which individuals could afford to procure and wear in battle, because in the earliest ages of all nations, men armed themselves as they best could, at their own expense, not that of the state, and consequently the richest were the best armed. As brass was the metal of which weapons of war, either offensive or defensive, were first formed, brass or copper, so many pounds weight, according to an estimate of the weight and value of the armour, formed the principle by which the successive classes were divided and arranged. Of these the first class contained all whose property amounted to, or exceeded, one hundred thousand pounds weight of copper. The soldiers of this class were required to be completely armed with greaves, coat of mail, helmet and shield of brass, besides the sword and the long pike. And as these were necessarily to advance in the front, and bear the shock of battle, and formed the flower of the troops, so their influence in the great military assembly was proportionate. They formed eighty centuries; forty between the ages of fifteen and forty-five, to serve in the field; and forty between forty-five and sixty, for the defence of the city. To this, the first class, the eighteen centuries of knights were added, so that it amounted in all to ninety-eight centuries. The second class contained those whose property fell beneath 100,000 asses, or pounds of copper, and above 75,000. These formed twenty centuries, and were less completely and expensively armed. The third class contained also twenty centuries, and its qualification was properly between 75,000 and 50,000 asses, or pounds of copper. Its armour was inferior to that of the preceding class. The fourth class contained those whose property was not beneath 25,000 asses; it amounted to twenty centuries, and its soldiers were not required to provide more than a pike and a javelin. These four classes composed the main body or phalanx of the army, when it was drawn up in that order of battle previous to the formation of the legion. The fifth class consisted of those whose property was between 25,000 asses, and 12,500; it formed the slingers and archers, or light infantry of the army, and was divided into thirty centuries.

The poorest citizens, whose property fell short of 12,500 asses, were regarded as supernumeraries in this division. Those who had above 1500 asses were still regarded as taxpayers, *assidui*, and were formed into two centuries, called the *accensi* and *velati*. They merely followed the army, and were only required to supply the places of those who fell. Below these came one century of the *proletarii*, whose property was between 1500 and 375 asses. These paid no taxes, had no military duty, and were only liable to be called on in great emergencies, as extraordinary levies, when arms were furnished to them at the public expense. One century more included all whose property, being less than 375 asses, was not worthy of being estimated, and who were called *capite censi*, and not liable to military service.

Three centuries of a different character completed the division, but these were not rated by their property, but by their occupation. These were,—one century of carpenters and smiths attached to the first class, and two of hornblowers, *(cornicines)*, and trumpeters, *(tubicines)*, attached to the fourth class.

From this brief outline of the comitia centuriata, the new national constitution given to Rome by Servius Tullius, it will be seen that it was a proof of very remarkable political wisdom in that legislator. The new citizens of Rome had been rapidly increasing in numbers and importance. A new tribe, the Luceres, had recently been raised to the possession of full political power. Three new equestrian centuries had been called into existence, though still in a subordinate position; and the body of the commons, the plebeian body, augmented by the arrival of free citizens from recently conquered Latin states, was gradually rising in importance, so as to point to the necessity of its obtaining a recognised position in the state; and at the same time to give to the hereditary patrician body no slight cause of alarm, lest it should soon become the most powerful body at Rome. By the Servian constitution, if we may so term it, the danger of any such revolution was averted by the admission of the plebs into a national council, without disturbing the proportions of influence due to the different bodies of which such a council was to be formed. The wealthiest men of the plebs would naturally be desirous of obtaining some share of that patrician dignity which they had enjoyed as Latins, before the annexation of their native states to Rome; and this desire was met by the creation of twelve centuries of knights, added to the equestrian order from amongst the plebeian tribes. These twelve centuries constituted a *nobility*, but yet were so connected with the eighty centuries which formed the great body of the first class, that they could not degenerate into an oligarchy. The first class, again, being formed of the wealthiest persons in the state, though far the least numerous, prevented the government from becoming a democracy of that ultra kind, in which numbers form the *ruling element*. In truth, property formed the *ruling element* in the Servian constitution; for the first class, containing ninety-eight centuries, even, without the addition of the *fabri*, formed the majority of the comitia centuriata, so that if all the centuries of that class were agreed on any point, it was carried without the votes of the other classes. The mere numbers of the lower classes very greatly exceeded those of the first class; but as property was assumed as the principle by which a century was to be formed, it required a great number of individuals to form a century of the requisite wealth. The proportion seems to have been regulated thus: the votes allotted to each class bore the same proportion to the collective sum of votes, as the taxable property of its members bore to the total taxable property of all the five classes; while the number of the citizens contained in each, stood in an inverse ratio to the numbers which designated their property. Although, therefore, the plebeians were now admitted into the full rights of citizenship, and to a voice in the government, still the power of deciding was vested in those who possessed the chief rank, wealth, and that natural influence which those who occupy a superior station always enjoy.

Perhaps the only fault of this new constitution was its premature establishment. It was in advance of the period to which it is always referred. The necessity of conferring the franchise upon the plebeians had not been sufficiently felt, consequently the patrician order, the ancient Roman populus, could not endure the admission of a new and recently conquered people to any thing even approaching an equality. Hence their enmity against Servius, and their concurrence in the ambition of Tarquinius, afterwards surnamed Superbus. On their part, it was a plot to overturn the new constitution, and deprive the plebeians of the rights and privileges conferred upon them by that wise and patriotic monarch. The introduction of the plebeians may perhaps have been too early even for their own good, as they had been too recently united to Rome to have thoroughly acquired the true Roman spirit; and they needed to purchase their privileges more dearly, by a lengthened and fluctuating struggle, in order that they might sufficiently prize them. For men always value most what they have with the greatest difficulty acquired. And, besides, the arrangement was too completely military to be perfectly adapted to the more peaceful spirit and structure of a purely civil economy. It was also of too sudden formation, not only that the people were not ripe for it, but that it did not, by its deliberate growth, tend to ripen them. In its gradual formation afterwards, every sucessive stage was sharply contested, and hardly won. The principles of law and justice, municipal and natural, on which they rested, were all made manifest in the course of the contest; so that not only a sound civil polity was at length established, but, at the same time, there was formed a code of laws based on principles so profound and true, as to entitle them to be retained as the foundation of all laws, to all civilized nations, from that period to the present, and probably to the end of time.

SECTION II.

C. 388.

Scarcely had the Romans succeeded in raising a portion of the city out of its ashes, when they were again involved in war. The various states and nations who had been reduced to subjection in previous wars, seemed to regard the humbled state of Rome as affording a propitious opportunity, not only of recovering their freedom, but of crushing a dangerous neighbour. The next year after the burning of Rome by the Gauls, the Latins and Hernicans revolted; while the Volscians declared open war, and invaded the lands of their weakened antagonist. But Camillus was at the head of the state, and his military genius enabled him to lead the feeble remains of the Roman armies to victory over their ungenerous foes. The Æquians had themselves suffered from the march of a part of the Gauls through their country into Apulia; yet they also took up arms against Rome, and were defeated. Meanwhile the Etrurians assailed the Romans in another quarter; and Camillus was compelled to march against them, when again victory crowned his exertions.

In a short time afterwards, the Latins and Hernicans having united their forces, struck such apprehension into the Romans, that as Camillus could not be spared from Rome, on account of the dissensions by which the state was agitated, Cossus was appointed dictator, and sent against them. He not only gained a complete victory over them, but also established a colony at Satricum. The Prænestines sustained a severe defeat; and on all sides the Romans repelled their assailants, and even began to extend the boundaries of the republic.

But while victory attended the Roman arms in these contests, the dangers arising from intestine broils became more and more urgent. The state of confusion in public matters, caused by the destruction of all public records, rendered it possible for the ruling orders to levy taxes and contributions from the plebeian order beyond their due proportion. That they did so may be fairly conjectured from the fact, that no accurate census was taken during fifteen years after the burning of the city, while taxes were levied by rates merely conjectural, and, we need scarcely add, with partiality and oppression. The building of the houses being, in a great measure, a public work, was done at the public expense, and the commons were, in many instances, enjoined to bear their proportion of the pecuniary burden, even after their whole property had been assigned to the patricians to whom they had been indebted. This necessarily plunged them deeper and deeper into debt; until the dungeons in the houses of the patricians became filled with their ruined countrymen in the sad condition of *nexi*, or persons assigned to slavery for life, for the payment of their debts. Censors had indeed been appointed, but no census was taken, so that the oppressive effects of continuing to exact a heavy tax from people whose property had already been alienated by debt, as if that property were still their own, continued unabated.

Manlius.

Manlius, the brave defender of the Capitol, took upon himself the dangerous task of defending the oppressed people. His seeming patriotism was, in all probability, increased by disappointed ambition, the influence of Camillus being too powerful for him. He publicly sold an estate, and with the produce paid the debts of a number of the oppressed plebeians. He next proposed the sale of public lands for the same object; and also accused the government of having concealed the money said to have been recovered from the Gauls, for the purpose of appropriating it to themselves. For this and similar conduct, he was accused of sedition and cast into prison; but so formidable was the appearance of his friends, that the senate restored him to liberty. This only encouraged Manlius to persevere in his violent course; and at last availing himself of his house in the Capitol he seized on that citadel, and was immediately accused of aiming at kingly power. On this accusation he was condemned to be thrown from the Tarpeian rock; his house in the Capitol was razed to the ground, and it was decreed that no member of the Manlian house should ever afterwards bear the name of Marcus. Such is the most common account given of this transaction; though there are others which differ considerably, both representing the conduct of Manlius in a much more favourable light, and relating his death differently. His death, however, unquestionably occasioned an accession of strength to the patricians, and in a corresponding degree weakened and dispirited the plebeians. Additional taxes were levied for the rebuilding of the walls; and by a sad consequence, additional debts were incurred by the oppressed commons, and greater numbers thrown into prison, or reduced to a state of servile dependence. All the privileges and rights for which the commons had so long and perseveringly striven, were wrested from them one by one, and the city seemed to be on the point of sinking into the wretched and powerless condition of being the abode of tyrannous patrician citizens, and degraded plebeian slaves.

Licinian law.

But two men, equal to the emergency, were raised up to rescue the Roman state from its danger. These were two of the tribunes of the people, Caius Licinius Stolo and Lucius Sextius. In their patriotic endeavours they were aided by the influence of Marcus Fabius Ambustus, whose daughter had been given in marriage to Licinius. By their energetic and persevering efforts these tribunes so ingratiated themselves with the commons, that year after year they were re-elected tribunes, gained over their colleagues, concentrated public opinion, met and counterbalanced the influence of the patricians, and after a struggle of five years, carried three new laws, which may be said to have completed the fabric of Roman liberty. One of these was an agrarian law, prohibiting

B. C. 366

any Roman citizen from holding more than five hundred acres of national lands; and also fixing the rent of public lands at the tenth of grain, and the fifth of the vintage and other fruit-produce. Another law ordained that one of the consuls should be chosen from the body of the commons. The third provided, that in cases of outstanding debts, all the interest which had been paid should be deducted from the capital, and that the remainder should be paid by equal instalments in three years. For the public influence thus obtained by the commons, the patricians endeavoured to compensate by the appointment of a prætor from their own body, and of curule ædiles; but the plebeians having obtained so much, could not any longer be prevented from attaining a perfect equality in point of eligibility to all public offices. In a short time afterwards, their participation in the other magisterial offices followed as a matter of course; the dictatorship, B. C. 353, the censorship, 348, the prætorship, 334, and even the priesthood, 300.

Thus at last the object of political equality between the patricians and plebeians was attained; and though the difference between patrician and plebeian families still subsisted, they gradually ceased to form political parties distinguished by origin and descent, yet there still remained the elements of strife between the wealthy and the poor, in which character all subsequent civil contentions at Rome ought to be considered. This we here deem it expedient to state distinctly, in order to guard the reader from the error of viewing the popular contests in which the Roman people were frequently engaged, after the passing of the Licinian laws, as merely a revival of the old feuds between the privileged patrician populus, or exclusive citizen-nobility of Rome, and the unprivileged, yet personally free commons, the growth of conquest, and forming the real strength of Rome. The early feuds were caused by the endeavours of the patrician populus to engross and retain all political power and privilege, and of the plebeian commons to secure personal liberty, and acquire civic and political equality. This was accomplished directly by, or soon in consequence of, the Licinian laws. But no public law can produce equality of wealth and influence: oppression may be prevented, sufferings may be mitigated, the growth of exorbitant wealth and power may be checked by wise enactments; but moral laws alone can prevent those inequalities of wealth and influence which must always exist, from becoming injurious, and finally destructive to any state, whatever be the excellence of its civil and political code.

Immediately after the conclusion of these civic struggles, the Romans were again engaged in hostilities against the Gauls and the Etrurians. Over both they were victorious; and in one of the battles with the Gauls, Titus Manlius, son of the consul, distinguished himself by slaying, in single combat, a Gaul of huge stature, despoiling him, in sight of both armies, of a gold chain, which the barbarian wore as an ornament, and throwing the bloody trophy around his own neck. For this exploit he received the name of Torquatus. Another Roman champion, Marcus Valerius, in another battle also slew a huge Gaul in single combat; in which, as tradition relates, he was assisted by a crow, and thence was named Corvus, or Corvinus.

Samnite war.

But while Rome was extending her dominions, and raising her military reputation in these conflicts, she was maturing her strength for struggles more formidable than any in which she had previously engaged. The Samnites, a people of Sabellian race, inhabiting chiefly a mountainous country, and celebrated for their courage and hardihood, made war upon the Sidicinians. They applied to the Campanians for aid against the Samnites; but both united proving too feeble, the Campanians applied to Rome; and the people of Capua declared themselves subject to Rome, that they might secure its protection. The Samnites refused to submit to the dictation of Rome, and prosecuted their hostilities against the Campanians. This produced a war between the Romans and the Samnites, by which the utmost strength of Rome was sternly tried. Several battles were fought, without producing any decisive results, though in general victory inclined to the Romans. On one occasion, the Roman army was in the utmost danger of being drawn into a disadvantageous situation in a narrow pass, and there surrounded, when it was rescued by the skill and courage of Decius, a military tribune, and a victory was gained over the Samnites. At length a truce was concluded for a period, both nations having suffered considerable losses

B.C. 343.

Latian war.

During the truce, the Latins continued to harass the Samnites; and when the Romans prohibited them, they declared war against Rome herself. This led to an unnatural war between nations that had for some time been almost completely blended. Manlius and Decius were sent against the Latins, and, in order to prevent the confusion that might arise between nations similar in language, arms, and discipline, the consul Manlius prohibited any Roman soldier from leaving the ranks on pain of death. But a daring Latin chief having challenged any Roman to single combat, the consul's own son could not brook that the haughty defiance should remain unanswered, quitted the ranks, slew his antagonist, and returning, laid the spoils at the feet of his father. The stern consul, though he had obtained his own name, Torquatus, from a similar gallant deed, immediately commanded the youthful champion to be beheaded on the spot, for breach of orders; disregarding the cries and entreaties of the soldiers, when they saw their young hero bound, and in a few seconds extended a headless trunk before them.

Decius.

A desperate engagement almost instantly took place, both armies striving at once for victory and for empire. The wing commanded by the consul Decius being on the point of giving way, he threw aside his armour, assumed a flowing robe of white, devoted himself with due rites to the infernal deities, for the safety of Rome, then mounting his horse plunged into the heart of the conflict, while his white robe streamed loose around his unarmed body. He soon fell, pierced by innumerable wounds; but the Romans believed that such a sacrifice necessarily secured the victory, while the Latins regarded it as equally ominous to them of defeat. The event was not long doubtful. The Romans were victorious in every quarter, and the Latins sustained a complete defeat. This battle is remarkable as being that in which the peculiar tactics of the Roman legion are first described by Livy; but whether the arrangement was the invention of Manlius, is not stated. The author of such a decided improvement in the art of war ought to have been made known; as there can be no doubt that the peculiar qualities of the Roman legion were greatly instrumental in achieving the empire of the world. See article Army.

B. C. 33

The Romans prosecuted their success with such vigour, that in the three ensuing campaigns Latium and Campania were subdued, and annexed as provinces to the territories of the republic. But the conclusion of one war was to Rome the beginning of another. The Samnites again took up arms, and were joined by the Lucanians. To resist his dangerous confederacy, the Romans mustered all their power, and placed Papirius Cursor at their head as dictator. Papirius reduced the enemy so much that they were glad to sue for a truce. But this was of no long continuance; and the Samnite general, Pontius, succeeded in drawing the Roman army into such a position that it could neither fight nor flee, being completely surrounded in a narrow defile called the Caudine Forks. The Roman soldiers were compelled to surrender at discretion, and were disarmed, obliged to pass under the yoke, and then dismissed with disgrace. This dishonour served only to rouse the indignation and the pride of Rome. Papirius was again chosen dictator, and again led the Romans to victory and revenge. The hum-

B. C. 32

bled Samnites once more sought a peace, which was soon afterwards broken.

C. 290.

In the renewed war, the Samnites were aided by the Etrurians, the Umbrians, and the Gauls. Against these confederate nations the Romans were led by consuls of unusual ability; among whom the skill of Fabius Maximus, and the self-devoting patriotism of Decius, rendered them conspicuous. After many gallant exploits, Decius, imitating the heroic deed of his father, devoted himself to the deities of death for his country's sake, and purchased victory at the expense of a consul's life. After numerous vicissitudes of fortune, which we cannot afford space to specify, victory declared for Rome. The Samnites lost their skilful general Pontius, and the Romans, under the command of Curius Dentatus, were enabled to dictate terms to their subdued antagonists.

entine
w

The Tarentines, and other states in southern Italy, had aided the Samnites, and were now afraid that Rome would take vengeance on them for their interference. They procured the assistance of the Gauls, in order to avert the war from their own territories. This expedient was crowned with but partial and temporary success. The Gauls were finally vanquished by Dentatus and Fabricius; and preparations were made for waging war against the Tarentines. Alarmed at the near approach of that vengeance which they had thus doubly provoked, the Tarentines applied for aid to the famous Pyrrhus king of Epirus. This brave and skilful, but rash and impolitic warrior, being desirous of emulating Alexander the Great, listened readily to the invitation of the Tarentines, cherishing a secret hope of conquering all Italy, and founding a western empire. He at first sent his favourite and political adviser Cineas to Tarentum, and soon afterwards followed in person, at the head of a large army, bringing with him also several elephants trained to war, the first time that such animals had been seen in Europe.

hus.

C. 279.

The first care of Pyrrhus was to increase his army, by the aid of as many auxiliary forces as he could procure, and to train them to the same discipline as his own. The Tarentines had expected him to bear all the toils and perils of the war, and to allow them to enjoy the pleasures of peaceful and luxurious indulgence. They soon found, however, greatly to their dissatisfaction, that their protector was resolved to be also their master; but their murmurs he suppressed without the slightest compunction. In the mean time P. Valerius Laevinus, the consul, at the head of a strong army, began to ravage the country of the Lucanians, who were in alliance with the Tarentines. This induced Pyrrhus to march against him, although his Italian allies had not joined him. A battle was fought on the banks of the Siris; and after an obstinate and bloody struggle, Pyrrhus obtained the victory, chiefly by means of his personal daring, his Thessalian cavalry, and his elephants, the Roman cavalry not being able to withstand the sight of these huge animals. But so desperate was the conflict, and so many of his best troops did Pyrrhus lose, that when his officers congratulated him on the victory, he exclaimed, "Another such victory, and I am undone!"

Soon after this encounter, Pyrrhus devastated the territories of the countries in alliance with Rome. He laid siege to Capua, surprised Fregellae, and invested Præneste, having advanced even within sight of Rome. Finding however that his march was producing no impression, he avoided an engagement offered him by Laevinus, and returned to Tarentum. What he had now learned of the Romans, convinced him that there was little prospect of an easy conquest over them; and he was very willing to enter into negotiations for a peace upon equal and honourable terms, his only stipulation being for an amnesty to the Tarentines, the Greek cities in Italy, and those states which had entered into an alliance with him. The senate seemed at first inclined to accept of these conditions; but they were dissuaded by Appius Claudius, who caused himself to be carried to the senate-house, blind as he was, that he might do his utmost to prevent a peace on any terms, except the immediate and unconditional departure of Pyrrhus from Italy. With this answer Cineas was obliged to depart from Rome, and both parties prepared for the renewal of hostilities. The consuls, P. Sulpicius and P. Decius, marched into Apulia, and were met by Pyrrhus near a little town called Asculum. There another battle was fought, which terminated in favour of the Romans, Pyrrhus finding it expedient to retire to Tarentum, and the Romans being in no condition to pursue, so obstinate had been the struggle, and so exhausted were both armies.

Pyrrhus, tired of a contest with such invincible foes, readily accepted an invitation from the Syracusans to assist them against the Carthaginians; and he passed over with a great part of his troops to Sicily. In that island he was at first successful; but fortune again began to frown upon him, and he was induced to relinquish his hopeless enterprise, and return to the aid of the Tarentines, who were nearly overpowered by the Romans. On his arrival, he recruited his army to the utmost of his power among the Samnites, Lucanians, and Bruttians, and prepared for a decisive effort. Nor were the Romans slack in their preparations: they sent the two consuls, Curius Dentatus and Cornelius Lentulus, at the head of two consular armies, the one into Lucania, the other into Samnium. Pyrrhus hastened to encounter Dentatus when separated from his colleague; and another desperate engagement took place near Beneventum. Pyrrhus had advanced incautiously in the hope of surprising the consul; and failing in this attempt, was obliged to risk a battle in a disadvantageous position, and where his phalanx had not proper room for its ponderous evolutions. The superiority of the legion over the phalanx, and of the soldier who fights for his country over the mercenary, were soon apparent. The elephants were scared by torches and driven back on the army of Pyrrhus; the phalanx was forced into a crowded confusion where it could not act, and from which it could not extricate itself; and in spite of the utmost skill and fierce valour of Pyrrhus himself, he sustained a complete rout, and fled with the wreck of his army to Tarentum. Thence he soon afterwards departed for Greece, leaving under the command of Milo, a small garrison in Tarentum, which shortly surrendered to the Romans. The Samnites were defeated with great slaughter, soon after the departure of Pyrrhus; and the Lucanians and Bruttians were also compelled to yield to the Roman arms. At the conclusion of this great war, Rome had established her supremacy over all the countries in Italy, from the northern frontiers of Etruria to the Sicilian straits, and from the Tyrrhenian sea to the Adriatic.

B. C. 272.

It cannot be doubted that the Roman arms triumphed in the Samnite, Latin, Etrurian, and Tarentine wars, very greatly in consequence of that cessation of civil dissensions which the Licinian laws had produced, and the corresponding accession of strength thereby gained. Yet even during these wars, there remained one grievance to be removed, and which was removed. The cruelty of a usurer towards one of his debtors, a youth of great personal elegance, excited the indignation of the people to such a degree, that the senate found it necessary to repeal the laws which gave creditors power over the persons of their debtors; and to enact, that thenceforth no person should be fettered and confined, except after conviction of a crime, and in order to punishment; and that for money due, the goods of a debtor should alone be answerable, and not his person. This enactment completed the charter of personal liberty to the Roman commons; but, as will afterwards be seen, it ultimately gave rise to consequences perhaps more fatal to public liberty.

B. C. 272.

The extensive conquests which arose out of these wars, gave occasion to the full development of the leading views of Rome, respecting the political relations in which it was her pleasure to place the conquered with regard to herself. The chief means to which, even from the earliest times, the Romans had recourse for the foundation of their dominion over the conquered, and at the same time for the prevention of the too great increase of the needy classes at Rome, was the establishment of colonies of their own citizens, which served also as garrisons in the captured cities in which they were settled. Each colony had its own internal constitution, formed generally on the model of that of the mother-city; hence it naturally became an object of Roman policy to keep the colonies in perfect dependence. This colonial system of the Romans, which necessarily arose out of the custom of depriving the conquered of their lands and liberty, assumed its main features in the Samnite war, and gradually embraced the whole of Italy. But the relations subsisting between Rome and the Italian nations were extremely various in kind.

A few cities and nations enjoyed the full privileges of Roman citizenship; in some instances, however, even these were precluded from the right of voting in the comitia. These were the municipal states. The privileges of the colonies were of a more restricted nature: they were indeed in possession of their own civic government, but had no share whatever either in the comitia or the magistracies of Rome. The other inhabitants of Italy were either federates *(socii, fœdere juncti)*, or subjects (*dedititii*). The federates preserved their own internal form of government, but were obliged to furnish tribute and auxiliary troops. Their further relation with Rome depended upon the specific terms of their league. The most advantageous of these terms were in favour of the Latins, though each of the Latin cities had its own separate league; as the rest of the Italian nations had their separate treaty, *(Jus Italicum)*. The subjects, on the other hand *(dedititii)*, were deprived of their internal constitutions, and were governed by Roman magistrates, annually renewed.

The internal constitution of Rome itself, now completed, bore the aspect of a democracy, inasmuch as equality of rights existed both for nobles and commons. Yet this democracy was modified by expedients so various and intricate; the rights of the people, the senate, and the magistrates, fitted so accurately into each other, and were so firmly supported by the national religion, connecting every thing with determinate forms, that there seemed to be no immediate reason to fear the evils of anarchy, or of military despotism; though the democratic character threatened the one, and the warlike temper of the nation the other, of these dangers. To obtain a right view of the constitution of Rome, thus modified, a few sentences stating the main outline may be given.

This constitution was not, as must already have been seen, the work of one great master-mind, but was the result of long contentions, innumerable temporary expedients, yielding successively as better were devised, aggressions mutually made by the opposing parties in their hour of strength, and concessions in that of weakness; and that steady equipoise obtained by the well-balanced action of opposing principles, knit together into the firmest and closest union by repeated heavings, subsidings, and conjunctions. The rights of the people consisted in the legislative power, so far as fundamental national principles were concerned, and in the election of the magistrates. The distinction between the *comitia tributa*, as independent of the senate, and the *comitia centuriata*, as dependent on the senate, still existed as to form, but had lost all its importance, the difference between patricians and plebeians being now merely nominal, and the establishment of the city tribes excluding the too great influence of the mere populace upon the *comitia tributa*. The rights of the senate consisted in administering and debating all ordinary national affairs, whether foreign relations, (war and peace only excepted, in which the consent of the people was necessary), financial concerns, or matters regarding domestic peace and security. But the manner in which the senate was supplied and maintained must have made it by far the most skilful political body at that time in the world. For a considerable period magisterial power had been the exclusive privilege of the patrician and senatorial order; but after the plebeians obtained equal access to these offices, the highest rank and power in the state offered a stimulus for exertion to the ambitious career of mental ability from every class and order, thus concentrating the collected mind of the nation, and from it forming a ruling body of unequalled wisdom, genius, and enterprise. The rights and rank of magistrates were founded on their right to the greater or lesser auspices, no public affair being undertaken without the auspices. He only, therefore, who was in possession of the rights of the greater auspices, could hold the highest civil and military power as dictator, consul, or prætor; such was not the case with those who held only the lesser auspices. The union of the highest civil and military power in the person of the same individual was not without inconvenience and danger; but military despotism was in some measure guarded against by the prohibition of any magistrate from possessing military command within Rome itself. But perhaps the most important of all the principles combined in the constitution of Rome, was the existence and recognised authority of its code of laws. To the sacred voice of public national law could appeal be made at all times, and on every occasion; and every civic struggle terminated by the addition of some new enactment, which defined the rights and privileges of the contending parties, and left a rule of conduct and a principle of appeal to succeeding ages. This ideal impersonation of law formed, on the one hand, a safeguard against the encroachments of the ruling power, or the deliberative body; while, on the other, the intemperate fervour of popular will was equally within its controlling influence. Religion and law were the ruling elements of the Roman constitution; and upon their inherent truth, purity, and power, or the reverse, depended the duration, or the ruin, of Roman virtue and Roman dominion.

Rome having now obtained the sovereignty of all Italy, was not long in finding employment for her victorious arms in another country. Sicily was the new field on which the strength of Rome was tried, and the Carthaginians were her new antagonists. It appears that a body of Samnite, or Sabellian youth, quitting their homes under the vow of a *sacred spring*,[1] had become mercenaries to Agathocles. After his death they seized upon the city Messina, in Sicily, and committed the grossest outrages upon the inhabitants. Having thus made the citizens, and indeed all the inhabitants of Sicily their enemies, these mercenaries (known by the name Mamertines, from the god Mamers, or Mars) sought the protection of the Romans. Some of them had previously applied to the Carthaginians; and while the Romans were hesitating about lending assistance to such disgraceful allies, the Carthaginians, somewhat less scrupulous, sent a body of troops, and took possession of the citadel of Messina. There had already been such intercourse between Rome and Carthage, as to make each city in some measure aware of the power and ambition of the other. The Roman senate speedily perceived, that if the Carthaginians obtained possession of Sicily, their own prospects of aggrandisement in that quarter would be at an end, and their formidable rival at the same time would have become their immediate neighbour.

---

[1] For an account of the *ver sacrum*, see Niebuhr, vol. i. p. 92.

irst Punic ar. C. 264.

An army under the command of the consul Appius Claudius was sent to the assistance of the Mamertines; and notwithstanding the superior power of the Carthaginians at sea, the consul found means to elude their fleet, and to take possession of Messina. Several victories were soon afterwards gained by the Romans; and Hiero, king of Syracuse, abandoned the Carthaginians, and formed an alliance with Rome. Agrigentum fell into the hands of the Romans after the defeat of a Carthaginian army, which had come to raise the siege, and the greater part of the interior of the island yielded to the power of Rome, while the fleets of Carthage kept possession of the sea-port towns, and thus maintained an equality. It was now evident to the Romans that the contest could come to no conclusion so long as their antagonists retained the supremacy of the sea; and they directed their most strenuous endeavours towards the construction of a fleet.

uilius.

Being aware of their inferiority in naval affairs, the Romans first availed themselves of a large Carthaginian vessel driven ashore in a storm, as a model; and to counterbalance their deficiency in skill as mariners, they invented a machine called a *corvus*, which served both as a grappling-iron and a draw-bridge, the object of which was to enable them to come to close quarters, and encounter the Carthaginians man to man. Trusting to this new invention, the consul Duilius hazarded an engagement with the fleet of the enemy, rushed alongside their ships, locked them fast in the grapples of the corvus, and captured at the first onset, by boarding, no fewer than fifty gallies. The Carthaginian commander saved the remainder of his fleet by instant flight. To commemorate this their first naval victory, the Romans erected in the forum a column adorned with *rostra*, or beaks of ships. In a second naval action, fought near the island of Lipara, the Carthaginians lost eighteen vessels, of which eight were sunk and ten taken.

C. 260.

After the war had lasted about eight years, the Romans determined to invade Africa, being aware that the tyranny of Carthage had alienated many of the African nations. A fleet of three hundred and thirty ships was equipped for this daring attempt, and given to the consuls Regulus and Manlius. The Carthaginians were again defeated with great loss, sixty-four galleys being taken, and thirty destroyed. The victorious fleet was soon refitted, pursued its course, and landed the army near Clypea. A rapid succession of victories led the Romans to the very gates of Carthage. Tunis was taken, and the humbled enemy sought terms of peace. Regulus imposed demands so harsh, that they resolved to continue the war; to which they were the more encouraged, by the opportune arrival of a band of Greek mercenaries under the command of Xanthippus, a Spartan of high military talents. The army being entrusted to his command, he completely changed its tactics, formed it on the Lacedemonian plan, and sought an engagement with the Romans. A great battle was fought, the Romans were completely routed, and Regulus himself taken prisoner. A Roman fleet sent to succour the army defeated the Carthaginian fleet in its course; and the army, though reduced, routed the Carthaginians, no longer led by the brave Spartan. Being too weak, however, to remain in Africa, and distressed for want of provisions, the army embarked for Italy; but a violent storm wrecked on the coast of Sicily no less than two hundred and ninety ships, with all on board. A second fleet was also destroyed in a storm; and the Romans for a time abandoned the sea.

In Sicily Metellus defeated the Carthaginians with great slaughter; and the Romans gaining the ascendency in that island, laid siege to Lilybæum. The Carthaginians, weakened and dispirited with their numerous losses, sent Regulus to Rome along with their ambassadors, expecting that he would persuade the senate to grant a peace. Instead of this, he dissuaded the senate, and recommended war, though aware of the sufferings he would have to endure on his return to Carthage. Some historians relate, that on his return he was tortured to death in the most cruel manner; others say that he was merely retained in close confinement, and died a natural death before the conclusion of the war. Again was the contest renewed, and at first not to the advantage of Rome. One fleet was worsted in battle, and another entirely destroyed off the coast of Sicily. The command of the Carthaginian forces in Sicily was given to Hamilcar Barcas, father of the celebrated Hannibal. By his skill and conduct the sinking cause of his country was vigorously sustained, till it seemed as if Carthage might yet be victorious. The Carthaginians made a last desperate effort to supply him with forces, and fitted out a large fleet for that purpose. The Romans had also redoubled their exertions for the same reason. The two fleets met near the islands Ægates, and the fortunes of Rome prevailed. A decisive battle was fought; fifty of the Carthaginian ships were sunk, and seventy taken, the power of Carthage was laid prostrate, and the empire of the seas transferred to Rome. Carthage was now obliged to accept whatever terms of peace Rome thought proper to propose: these were, that they should evacuate all the islands in the Mediterranean, restore the Roman prisoners without ransom, and pay for the defraying of the expenses of the war a thousand talents of silver immediately, and two thousand two hundred in the space of ten years, in equal payments.

B. C. 241.

Thus ended the first Punic war, after a contest of nearly twenty-four years' duration. Its vicissitudes had severely tried the strength and the resources of Rome; but it extended her reputation and her political connexions very widely, preparing her for a career of foreign conquest. It awoke also in both republics, Rome and Carthage, an inextinguishable hatred of each other, such as could never be appeased but by the ruin of the one; and it inspired Rome with a desire of foreign conquest and dominion, and of the wealth to be thus gained, which speedily introduced corruption into the state, along with that accumulation of power in the hands of a few families, which in every country long wars inevitably confer on able warriors. In this manner the seeds of Roman greatness and Roman decay were sown at once, and began to grow up side by side. Their further progress we shall afterwards have occasion to notice and explain.

The peace which Rome enjoyed at the termination of the first Punic war was of no lengthened duration. The first hostilities in which she was engaged were directed against Teuta, queen of Illyricum. The Illyrians had been successful in a war against the Ætolians; and in the pride of their victory, they caused their fleets to scour the seas, and pillage those of every other nation without distinction. In this piratical warfare some Roman ships were taken and plundered; and the Illyrians laid siege to Issa, a city which had put itself under the protection of Rome. When the Roman ambassadors demanded restitution, and required Teuta to restrain her subjects from such piracies, she both returned a haughty answer, and procured the murder of the ambassadors. Upon this the Romans declared war against the Illyrians. In the course of the war they gained the naval supremacy over the Adriatic, subdued the Illyrians, and entered into alliance with the various states of Greece which had suffered from the depredations of the Illyrian pirates. This alliance was of the utmost importance to Rome, not only in opening the way for her future interference in the affairs of Greece and of Asia, but also in enabling her to divide her enemies, and prevent the formation of dangerous confederacies against her, when not prepared to meet them.

B. C. 230.

The Illyrian war had scarcely terminated when one of a more formidable character commenced with the Cisalpine Gauls. Tribes of that great people had repeatedly served as mercenaries against Rome during the Etruscan and Samnite wars. After the conclusion of these wars, the Romans subdued the Livonian Gauls, and planted a colony in their country near Lena. A new influx of the Transalpine Gauls B. C. 226. gave courage to their countrymen to renew the war, and a furious contest soon began. The Gauls were at length defeated with great slaughter near Clusium; and the Romans following up their success, invaded the Gallic country around the Po. The Gauls were again defeated by Marcellus, and compelled to sue for peace, which the Romans granted, establishing at the same time colonies at Placentia and Cremona. It seems worthy of record, that the number of men capable of bearing arms throughout the Roman dominions in Italy, as ascertained by the levies of that dangerous juncture, amounted to 800,000.

Meanwhile the Carthaginians had been making great exertions to recruit their strength for another struggle with their great rival. Being prohibited from extending their influence in Sicily, they had sought compensation by attempting the subjugation of Spain. The command of their armies in Spain had devolved upon Hannibal, the son of that Hamilcar who had distinguished himself towards the close of the former war in Sicily. The father of Hannibal had made him swear perpetual hostility to Rome; and from his boyhood his mind had been continually engaged in devising the ruin of that detested city. He had prosecuted his conquests in Spain with the view of obtaining a veteran army, and a source of auxiliary supply from the warlike nations in that country; and when his designs were matured, Second Punic war. B. C. 218. he laid siege to Saguntum, which was understood to be under the protection of Rome. Having treated with contempt the remonstrances of the Roman ambassadors, he took possession of this city. The senate of Carthage having approved of his conduct, war was declared, and both parties prepared for the impending conflict, well knowing that its progress must be sanguinary, and the result ruinous to the one or the other of the rival republics. (As this war is detailed at some length in the article Carthage, we must refer to it for a more particular account of the contest.)

Hannibal having completed his preparations, set out from Spain, for the invasion of Italy, at the head of a veteran army of 50,000 foot, and 9000 horse. He rapidly traversed Gaul, crossed the Rhone, and commenced the passage of the Alps, led by Insubrian guides. This almost impracticable attempt he achieved in fifteen days; and, on mustering his army in the plains of Insubria, found it reduced to 20,000 foot, and 6000 horse. His army was soon considerably increased by the Gallic nations; and, in a comparatively slight encounter near the Ticinus, he worsted the consul Scipio, and soon afterwards completely defeated Sempronius near the Trebia. The victorious Carthaginian then advanced towards Rome, devastating the country through which he was marching, and making it his object to irritate the impetuous spirit of the consul Flaminius. In this he was completely successful, and having drawn him into an ambush at the lake Thrasymenus, entirely defeated B. C. 217. him. The consul himself fell in the battle, with 15,000 of his bravest troops, and a great number were taken prisoners. Such was the fury of the encounter, that the combatants were insensible of the shock of an earthquake which happened during the engagement.

Rome was now in a state of great alarm, having suffered successive defeats in Italy itself, and seeing the victor pursuing his course unchecked through the land. Fabius Maximus was chosen dictator, and immediately adopted a totally different plan of opposing the enemy. He studiously avoided battle, kept his army on the hills, watched Hannibal, cut off his supplies, and did every thing calculated to wear out an invading army, which is necessarily remote from its supplies. By this skilful policy he both saved his own army, and greatly harassed that of his antagonist; and from it was surnamed Cunctator, the Delayer.

The Romans having recovered from their consternation, raised another levy of troops, augmenting their armies to 87,000 men, under the command of Terentius Varro and Æmilius Paullus, of whom the former was rash and headstrong, the latter a cautious imitator of Fabius. Availing himself of the impetuosity of Varro, Hannibal obtained his B. C. 216. wish in a general engagement near Cannae in Apulia, where, by his superior skill, he inflicted on the Romans the most dreadful overthrow they had ever sustained since the battle of Alia. The consul Æmilius, and about 45,000 men, of the very flower and strength of his army, were left dead on the field, and about 10,000 were taken in the pursuit. Rome seemed now open to the conqueror; but his army had suffered too severely to venture on so hazardous an enterprise, and he turned aside to Campania, and wintered in Capua.

It was manifestly Hannibal's object to encourage the states of Southern, or Lower Italy, to revolt against Rome, that he might recruit his forces from among them, and so be enabled to continue the war with renewed strength. To a considerable extent he was successful, especially among the Lucanians, Bruttians, Apulians, and even Campanians. He sent Mago to Carthage, to urge them to transmit supplies with all possible despatch, that he might follow up his blow, before Rome should have recovered from her consternation. But though the Barcine party predominated in the Carthaginian senate, such was the influence of the opposite faction, that he obtained only a very limited number of supplies; and these were to be sent to Spain, whence he might draft a corresponding number of the veteran troops stationed there. This, indeed, was part of Hannibal's original plan, that he might have at least one resource beyond the caprice of faction, though greatly too remote from the scene of action to be immediately or securely available.

At Rome the greatest exertions were made to remedy the disastrous consequences of the terrible defeat of Cannae. All ranks and every age, from the boy of seventeen to the retired veteran, were enrolled; and nearly all the gold ornaments worn by persons of wealth and distinction, were voluntarily given up to meet the exigencies of the state. In a short time an army was raised, superior in numbers to that commanded by Hannibal; and the celebrated Marcellus was placed at its head. In vain had Hannibal waited at Capua for supplies from Africa; none were sent, and he was obliged to prepare to contend singly against Roman courage and Roman despair. He sustained a check at Nola; and not long afterwards Marcellus inflicted on him a partial defeat, by which the courage of the Romans was greatly restored. The tide of success began now to recede from Hannibal. He was unable to prevent the Romans from besieging and taking Capua, though he both attempted to storm their camp, and, failing in that, marched to Rome, to call away their armies for the defence of the city. They disregarded his threatening demonstration, continued the siege, took the city, and inflicted severe punishment on the Capuans.

The fall of Capua was highly injurious to Hannibal, tending to discourage other Italian states from joining an ally who could not protect them against the fierce vengeance of Rome. On this account he failed to obtain supplies to his waning army, while the Romans speedily replaced every loss with fresh recruits. These hopes being frustrated, Hannibal entered into an alliance with Philip king of Macedon; but here the fortunes and the policy of Rome likewise prevailed. The Illyrian war had caused the Romans to be regarded as protectors by the Grecian states, who, at the same time, were jealous of the power of Philip. No sooner, therefore, did the Macedonian king manifest his disposition to form a confederacy with Hannibal against Rome, than the Roman ambassadors were able to excite against him such hostility among the neighbouring states of Greece, as to prevent the possibility of his making a descent on Italy to aid the terrible Carthaginian. This is a very striking instance of the deep policy of Rome; by means of which she was always able to keep a powerful enemy in check till she might have leisure to collect her strength for a decisive effort.

Notwithstanding these disappointments, Hannibal continued to maintain his ground, repulsing the most daring assailants, and out-manœuvring the most skilful. Marcellus, who had conquered Sicily, and again returned to Italy, and who was the most gallant opponent ever Hannibal met, was at last drawn into an ambush and slain. But still, without supplies, the Carthaginian army must melt away; and Hannibal's hopes of ultimate success now depended upon the army led by his brother Asdrubal reaching him safely from Spain. His hopes from Sicily, Macedonia, and Africa, had failed; though it was doubtless to secure them that he had made Lower Italy the basis of his operations; and he now waited eagerly the arrival of his brother. Asdrubal had in the mean time left Spain, crossed the Pyrenees, and the Alps, and entered Cisalpine Gaul, where he was joined by considerable numbers of the natives. A messenger, whom he sent to apprise Hannibal of his approach, was intercepted; the consul Nero hastened to join his colleague Livius, and assailing Asdrubal on the banks of the Metaurus in a disadvantageous position, they completely routed his whole army. B. C. 207. Asdrubal himself was slain, and 56,000 of his army fell with him on the fatal field. The first tidings which Hannibal received of his brother's defeat and death, was by the head of that luckless brother being thrown into his camp. From that time forward the contest was without hope on the part of the Carthaginians. The Roman consuls were not indeed able to cope with even an enfeebled army commanded by Hannibal; but the youthful Scipio, having been sent to Spain, speedily overran it, and reduced the greater part of it to complete subjection, putting an end to Carthaginian power in that quarter. On his return he obtained permission, against the opinion of Fabius, to transfer the war to Africa.

The invasion of Africa by Scipio, so alarmed the Carthaginians, that they immediately recalled Hannibal from Italy for the defence of Cathage itself. To this command Hannibal most reluctantly submitted; and quitted Italy with expressions of the utmost mortification and regret. In the mean while, Scipio had approached to the near vicinity of Carthage. The two armies met at Zama, to decide the fate of Rome and Carthage, and, with them, of the world. The battle was obstinate and bloody, but the Roman army was decidedly superior in numbers, and still more so in that high hope which so often determines the day; so that, in spite of the utmost exertion of his unrivalled military skill, Hannibal saw his army completely overthrown. Carthage had now no resource but in peace; and she was compelled to submit to the terms dictated by Scipio. These terms were abundantly severe; that the Carthaginians should retain in Africa only the territory annexed to their government; that they should yield up all their elephants, and all their ships of war, except ten triremes; that they should pay at specified times ten thousand talents of silver; that they should commence no war without the consent of Rome; and that they should restore all Numidia to Massinissa, and give an hundred hostages for the performance of the treaty. Thus ended the second Punic war, after having shaken Rome to her centre, and threatened for a time to change the destinies of western Europe, and, with that, the destinies of mankind; yet the result was exactly correspondent to the character and resources of the two great rival republics.

B. C. 201. Rome had now removed her mighty rival from the strife of nations, and saw the sceptre of universal dominion but little removed beyond her own grasp. The Roman senate had fully entered upon that course of far-sighted policy, which enabled them to gratify and amuse the nation with foreign conquest, the wealth and powers of which they almost wholly engrossed. Such was its aspect and aim at home; while with regard to foreign nations, the constant policy pursued was to grant assistance to the weaker states against the stronger, and by taking them under Roman protection, to have at all times the means of provoking a contest, whenever it seemed conducive to her interest. The character of Rome, as a great military republic, was now completely developed, as the overbearing friend or the jealous foe of every other state.

Macedonian war.

The next field of Roman warfare was Macedon. Philip, the king of that country, ambitious of obtaining the sovereignty over Greece, made some aggressions on the Athenians. They complained to Rome, which soon led to a declaration of war against that monarch, and the sending of an army to carry hostilities into his dominions. The management of the war was entrusted to T. Quintus Flaminius, whose diplomatic skill was still more conspicuous than his military talents. After several inferior engagements, a great battle was fought at Cynoscephalæ, in which the Macedonians were completely routed, B. C. 197. and Philip compelled to submit to such terms as the conqueror pleased to dictate. The chief of these were the reduction of his fleet, and his abandonment of all pretensions to the sovereignty of Greece, the various states of which were taken under the protection of Rome. B. C. 196. At the conclusion of this war, the politic Roman, or rather the wily Italian, caused the liberty of Greece to be publicly proclaimed at the Isthmian games; while the lavish expressions of gratitude uttered by the thoughtless crowds were the gilding of the chains by which they were securely fettered.

Syrian war.

Rome still regarded Carthage with a jealous eye, and could not feel secure so long as the dreaded Hannibal influenced her councils, and might again lead her armies. Fearing that his dispirited countrymen would surrender him to his implacable enemies, that great man fled to the court of Antiochus, king of Syria. About the same time the Ætolians, being dissatisfied with the conduct of the Romans, besought the aid of Antiochus, who was already quite disposed to interfere in the affairs of Greece. He accordingly seized upon Eubœa, and proceeded to take measures for additional aggressions on states which claimed the protection of Rome. War was immediately declared against him, and an army sent into Greece, under the command of the consul Glabrio, who defeated the Syrians at the pass of Thermopylæ. Next year Lucius Scipio, brother to the conqueror of Carthage, Africanus, was sent against Antiochus, accompanied by his brother as legate. B. C. 190. They reduced Greece to subjection, and crossing into Asia, defeated Antiochus in a great battle at Magnesia. Antiochus purchased peace, by resigning all his possessions in Europe, and those in Asia north of Mount Taurus, paying 15,000 Eubœan talents, and promising to give up Hannibal. The latter vindictive article caused the flight of Hannibal to Prusias, king of Bithynia; B. C. 183. but being still pursued by the remorseless hatred of Rome, he put an end to his mortal existence by swallowing poison, which for such an emergency he always carried with him.

The war with Antiochus fairly introduced Rome to the beginning of her oriental sovereignty; and the battle of Magnesia may be viewed as the event which terminated the Grecian or Macedonian sway as a universal empire. Little absolute territory was indeed gained by Rome in this preliminary war; but at its conclusion she saw both Macedon and Syria reduced to a state of dependence on her imperious will, with the Grecian states in the condition of ready instruments in her hands of future aggrandisement, whenever she might be disposed to take or make an opportunity.

B.C. 183.

It is even painful to state, that after the conclusion of the Antiochian war, the two Scipios were accused of having received bribes from that monarch, and of having embezzled the public money. Africanus went into voluntary exile at Liternum, where he died the same year that Hannibal fell a victim to the cruel and mean revenge of Rome. Asiaticus refused to pay the fine exacted, and all his property was confiscated.

B.C. 170.

B.C. 168.

A new Macedonian war soon arose, caused by the imperious authority assumed and exercised by the Roman ambassadors over the conduct of the king. Philip had endured their control with impatience; but his son Perseus was less able to suppress his dissatisfaction, and hostilities were soon commenced. The war for a time was favourable to the Macedonians, who gained one considerable victory, and were successful in several conflicts of smaller importance. At length the command was given to Paulus Æmilius, an old and skilful general, under whose care the aspect of affairs changed. A decisive battle was fought near the city Pydna, remarkable as the conclusion both of the Macedonian kingdom and the Macedonian phalanx. In the first shock of battle the phalanx was irresistible, and bore down all opposition; but the skilful Roman general, by causing his men to retire fighting, and lead the phalanx upon broken and uneven ground, obliged it to open its dense array of serried pikes, when the legionary soldiers immediately penetrating these openings like a wedge, rent asunder the unwieldy mass, and scattered it into hopeless and irretrievable confusion and rout, like the bursting of a cloud of vapour by a whirlwind. Perseus was captured soon after the battle, and reserved to grace the victor's triumph. Macedonia, Epirus, and Illyricum, were reduced to the condition of provinces, and the foundation of a foreign territorial empire laid, was instead of one merely of influence and military power.

Third Punic war.
B.C. 150.

The utter destruction of Carthage was next resolved upon, partly through the vindictive remembrance of the terror which Rome had formerly felt from Carthaginian prowess, partly from the instigation of the stern, haughty, and implacable Cato the censor. A pretext for a war was not difficult to find, though the Carthaginians endeavoured to avert their fate by even the most abject submission. But when the Romans, after inducing them to yield up their weapons, informed them that they must abandon their city, witness its demolition, and remove to a new position remote from the sea, despair itself roused them to make the fiercest resistance. They sprung at once into an attitude of the most determined defiance, forged new weapons, framed new military engines, the women cutting off their hair to form ropes to work their machinery; and clad in glittering panoply, they manned their walls, and met the unappeasable hatred of Rome with hatred not less keen and mortal. The Roman armies sustained several reverses; but under the command of Scipio Æmilianus, son of Paulus Æmilius, and adopted son of Scipio Africanus, victory again began to crown their efforts. After a fierce and protracted struggle, the Romans forced their way into the city on the side next the port, and obtained possession of the city wall. But the conflict was not over though the city wall was seized. The Carthaginians fought from street to street, from house to house; and the Romans gained the city but by yards and inches, every house being contested from the ground floor to the roof, like a separate fortress. At length all was carried but the citadel and the temple of Æsculapius. These the Romans were prepared to storm, when the citadel surrendered, Asdrubal, who had the command, yielding to Scipio, on condition that his life should be spared. Those who had fled to the temple, some of whom were deserters from the Roman army, prepared to destroy it and themselves by fire, rather than fall into the hands of the Romans. Among these was the wife of Asdrubal, who had been placed in the temple before her husband yielded to Scipio. Seeing Asdrubal along with the Roman general, and detesting his cowardice, she arrayed herself in her richest attire, took her two children with her, and displaying herself on the top of the temple, upbraided her husband, stabbed her two children before his face, and threw them into the flames, which were now bursting furiously from the interior. She then sprung after them into the heart of the blazing ruin. Thus perished Carthage, leaving Rome to pursue unrivalled her guilty and self-destroying career.

B.C.

B.C. 1

While the third Punic war was still raging, hostilities again broke out in Macedonia, excited by an impostor named Andriscus, who, pretending to be the son of Philip, instigated the disaffected Macedonians to throw off the Roman yoke, and forming an alliance with the Thracians, strove to accomplish his purpose by force of arms. Metellus, after a short struggle, overpowered the insurgent Macedonians, and then attempted to procure the dissolution of the Achæan league. This led to the Achæan war, which terminated in the complete subjugation of Greece, and its reduction to the form of a Roman province. Mummius the consul, who conducted this war, sacked and burned Corinth; and after having pillaged the city of its most valuable effects, its rich paintings and beautiful sculptures, demolished its walls, temples, and public buildings, and reduced it to a heap of blackened ruins. The plundered ornaments of Corinth were sent by the consul to Rome; and it has been recorded, proving at once his care and his ignorance, that he stipulated with the masters of the vessels employed in transporting these matchless treasures of art, that "if they suffered any of them to be lost or injured, they should furnish others in their stead."

War in Spain.

B.C. 1

Another enemy of still more stubborn mould continued to engage the attention of Rome, and to put to the severest test the courage of her armies and the skill of her generals. The wars and conquests of the Carthaginians in Spain had directed the attention of the Romans to that country; and a war for the awowed purpose of its subjugation was begun soon after the expulsion of the Carthaginians. Partly in consequence of the defensible nature of the country, abounding in mountain ridges and deep and rapid streams, and partly from the brave and determined character of the inhabitants, the war was protracted, obstinate, and bloody. Repeatedly did the arms of Rome sustain signal reverses; and still with invincible energy of will was the contest maintained. At length the Lusitanians obtained a leader under whom they seemed likely to secure their possession of liberty and independence. This was Viriatus, a shepherd, a hunter, a robber, and finally a military hero, almost unrivalled in fertility of resources under defeat, skill in the conduct of his forces, and courage in the hour of battle. Like the guerilla leaders of modern times, he knew how to avail himself of the wild chivalry of his countrymen, and the almost impenetrable fastnesses of his country; but, superior to them, he was equally able to guide a troop and to marshall an army. Six years did he maintain the contest; and at length the consul Cæpio, unable to subdue him in the field, procured his assassination. The Lusitanians, deprived of their brave leader, were soon afterwards completely subdued.

Undismayed by the overthrow of their countrymen, the Numantines still maintained the unequal conflict against the collected might of Rome. Pompey was baffled; his successor Mancinus shared a similar disgrace; and at length the Romans raised Scipio Æmilianus, the conqueror of Carthage, to the consulship, and assigned him Spain as his province, and even prolonged his command, after the expiration of his year as proconsul. At the head of a large army he closely invested the town, and began the siege. The Numantines made the most desperate defence; and after more than six months of almost incessant assault and repulse, the citizens destroyed their wives and children, set fire to the city, and by the flames or mutual slaughter perished to a man, leaving to Scipio to triumph, not over Numantia, but over the smouldering tomb of its unconquered children.

B.C. 133.

Attalus.

Amidst these triumphs of her arms, the policy of Rome obtained an acquisition more important in some respects, but also of darker omen. Attalus, king of Pergamus, at his death, bequeathed his dominions to the Roman republic; and the senate, disregarding the remonstrances of Aristonicus, the natural heir, immediately took possession of this valuable inheritance. By what means Attalus had been induced to make this strange bequest, has never been accurately stated; but thus, by some deep stroke of policy, Rome acquired possession of the largest and fairest portion of Asia Minor. The extensive provinces now held by Rome caused a very great and fatal alteration in part of her international policy. The inhabitants of these countries were entirely subject to Rome; and the administration of them was conducted by those who had enjoyed the office of consuls, and by prætors, subordinate to whom were the quæstors, or collectors of the revenue. Till about this time prætors were expressly appointed to each province; but it now began to grow customary for the prætors who had vacated office to succeed to the provinces, under the name of proprætors. The highest military and civil powers were united in these governors; and being thus prolonged in a species of self-appointed and irresponsible tenure of office, the consequence was equally injurious to the provinces, in the oppression and extortion inflicted on them, and to Rome, in the degeneracy thus fatally introduced. From this time forward Roman virtue was little but a name; while the armies and generals of the haughty and corrupt republic fought not so much for fame and dominion, as for the means of gratifying licentiousness and avarice.

Seditions of the Gracchi.

The destructive consequences of Roman corruption and degeneracy soon became but too manifest in the seditions and civil broils which sprung up, and found no end but in the overthrow of the republic itself. It may be expedient to devote a few sentences to an explanation of the causes and the nature of the dissensions by which the very existence of the state was endangered; especially, as owing to the resemblance which they bear to the ancient contests between the patricians and the plebeians, they are liable to be misunderstood, as if they were merely a renewal of those ancient broils.[1] They were, however, essentially different. The contests between the patrician populus and the plebeian commons of Rome's earlier days was for the possession of the rights and privileges of citizenship, which was at first enjoyed by the patrician order alone, and for an equal share in which the plebeians strove. These contests had terminated soon after the passing of the Licinian law, and the admission of all orders alike to an equality in rights, privileges, and eligibility to all offices in the state. From that period, though the designations of patricians and plebeians might still be retained, the essential distinctions between them had ceased to exist; and whatever contests arose, sprung from causes entirely different.

Although there had long ceased to be any legal distinction between the patricians and the plebeians, so that they could not accurately be regarded as different orders in the state, yet there continued to subsist the great difference between wealth and poverty, aggravated by the fact, that the senate wielded the entire power of the republic, and in general engrossed its emoluments. In consequence of this exclusive possession of power, the senators had gradually acquired the almost equally exclusive possession of that portion of the lands of conquered states which the laws of Rome devoted to the commonwealth. The Licinian law had been passed to prevent this unjust seizure of the public lands by the patricians, but was insufficient for that purpose, even its author being convicted of violating it soon after its enactment. While the attention of the state was almost incessantly occupied with the management of public wars, the senatorial body imperceptibly gained possession of the public lands, by grants, by pretended purchase, or in some instances by fair means, farming them from the state, in others by forcible seizure. In this manner the patricians, though no longer a peculiar order, possessing distinctive privileges in the state, became a wealthy and powerful aristocracy, engrossing nearly all public influence by means of their wealth, as their ancestors had done by means of their exclusive citizenship.

On the other hand, the great body of the citizens, deprived of their due share of the public lands, and not permitted by law to engage extensively in commerce, which was the privilege of the equestrian order, possessed the rights of freemen, and the privilege of voting, as citizens in all public matters in the comitia, notwithstanding their extreme poverty. Not obtaining their due share of the public lands, and not being permitted by the wealthy patricians to farm them, which they rather entrusted to their slaves, these poorer citizens were reduced to the necessity of resorting to Rome, and attaching themelves to one or other of the more powerful and wealthy of the patricians, by whom they were supported in return for their votes in the comitia. Thus the wealth of the one partly enabled them to purchase, and the poverty of the other obliged them to sell, those rights of voting on all public matters, which, instead of being the safeguards of freedom, became the very elements of tyranny and licentiousness. This consequence seems to have been foreseen, and partly guarded against, by the institution of the city tribes, for the purpose of preventing the undue influence of what was truly a city rabble, devoid of the means of subsistence, although voting in the public assemblies. But this preventive measure was not sufficient. The immense wealth which flowed into the public treasury from the tribute of conquered provinces, and into the coffers of the chief senators, from their public lands, the command of armies and of provinces, together with other public employments, enabled the state, as such, to maintain in idleness, by donations of money and provisions, great numbers of the people, whose votes they thus secured; and the wealthy families to maintain great numbers more, who might be either added to the supporters of the senate, or employed as the partizans of ambitious individuals. In this manner did it come to pass, that the main body of the citizens of Rome had sunk to the very lowest depth of poverty and venal degradation, and was ripe for any sedition or the perpetration of any crime. At the same time these idle and dependent citizens must have been often exposed to the real ills and sufferings of poverty; and must have been often impelled to view with bitter envy the excessive wealth of their more fortunate countrymen, whose equals nevertheless they knew themselves to be in the eye of the law. That feelings fiercely democratical should spring up in the breasts of those who were at one time supported, and at another time trampled on, by a proud and avaricious aristocracy, which the senate had become, was both natural and inevitable; and that some measure should be framed to check the increasing disparity between the wealthy and the poor, and to prevent the enormous accumulation of wealth in the hands of the senate as a body, or of a few families in that body, was absolutely indispensable to the permanent well-being of the republic. But such a measure would have required to be framed with the most consummate judgment, and conducted with the utmost skill, caution, and prudence, as its failure could not but aggravate all the evils which it had been intended to cure.

---

B.C. 133.

Tiberius Sempronius Gracchus.

In this crisis of affairs at Rome, when a conflict was on the eve of bursting forth, not between patricians and plebeians, as distinct orders in the state, but between the rich and the poor, on account of the unequal distribution of property, Tiberius Sempronius Gracchus appeared on the scene, and assumed the advocacy of popular rights. He was a man of great natural abilities, which had received the utmost degree of cultivation, through the care of his mother, the celebrated Cornelia, and the example of his relatives, the Scipios. Circumstances had led him to mark the baneful practice of the wealthy families, in assigning to slaves the cultivation of their lands, and thus causing the removal to the city of that class of free and privileged men, who ought to have been the main proprietors and tenants of the soil, which the valour of their fathers and of themselves had won for Rome. The evil consequences of thus forming a population of agricultural slaves, and needy citizens prepared for every enormity, both by their degradation and their distress, arrested the attention of Gracchus; and he resolved to exert himself for the removal of that corruption which was already preying so deeply on the vitals of the commonwealth. His desire was to relieve the distress of the lower orders, and to prevent the danger of their relapse into an equally unfavourable condition. Having been elected tribune of the people, he availed himself of his official power, and proposed a better division of the public lands. At first he sought merely the re-enactment of the Licinian law in a modified form, somewhat better suited to the altered circumstances of the republic. In this he was strenuously opposed by the senate, and also by one of his colleagues in the tribunate, Octavius. The opposition, instead of inducing Gracchus to adopt more prudent methods of conciliation, roused his indignation, and from a patriot, anxious only to promote the public weal, converted him into a demagogue, determined to effect his purpose by whatever means and at whatever hazard to his country's welfare. He brought forward a new law much more harsh in its provisions than the Licinian; and being still opposed by Octavius, he procured his ejection from the tribuneship, contrary to the principles of the constitution, which he thus himself set the example of violating. He then carried the new law, and got himself, his brother, and his father-in-law appointed as commissioners for surveying the public lands, and taking steps preparatory to a new division.

Had Gracchus contented himself with these enactments, and done his utmost to carry them into peaceful execution, he might after all have been regarded as a true patriot, and might have been the preserver of his country; but he now found himself in the position, into which, sooner or later, every demagogue finds himself driven. It had become necessary for him to retain popular support, even for his own personal safety, if he should remain at Rome after the expiration of his year of tribuneship. He therefore introduced other measures more calculated to maintain his popularity, than to promote the true interests of the community. He proposed a distribution of the treasures of Attalus among the people; a reduction of the period of military service; and the right of appeal from the sentence of the judges to the people. Measures so glaringly democratic incensed the senate to the very highest degree; and as his tribuneship was now nearly expired, during which his person was inviolable, he endeavoured to procure his re-election as a tribune, both that he might retain the power of pressing forward his proposed enactments, and for the security of his personal safety. The aristocratic party in the senate were now resolved to have recourse to any method of removing such a dangerous foe. They mustered all their partizans, disturbed the proceedings of the comitia, and interrupted them both by intrigues and violence. At length, on the second day of the comitia, held for the election of tribunes, when both parties had mustered in full force, Tiberius wishing to inform the people that his life was in danger, and the tumult being too great for him to be heard, raised his hand to his head; this gesture the opposite party misinterpreted into a sign of his wish that the people should crown him; and Scipio Nasica rushed out of the senate-house at the head of the most determined of its members, loudly accusing Gracchus of a conspiracy to make himself king. A fierce conflict ensued, the friends of Gracchus dispersed and fled, and he was killed during the confusion of the tumult. About three hundred of the democratic party fell along with their leader, and their bodies were cast into the Tiber.

B.C. 13

Thus terminated the attempt of the elder Gracchus to reform the abuses which were rapidly destroying the virtue of the Roman state and people; and like all unsuccessful attempts, it but served to consolidate more firmly what it had shaken, but not removed. The senate did not indeed venture directly to repeal the Sempronian law for the division of the public land, which had superseded that of Licinius, but left it to fall into desuetude like its predecessor. In the contest, however, both parties had been guilty of the most glaring violations of both law and justice; both parties contemned the fundamental principles of the constitution; and both manifested an utter disregard for the true welfare of the republic, in their eager endeavours to prosecute their self-interested views. How different from the early struggles between the patrician and plebeian bodies, in which no blood was shed by either party, and the utmost that even the oppressed plebeians threatened, was to forsake the city which denied them the rights of citizens! But the love of country had perished in the sordid pursuit of wealth; and there no longer remained enough of true patriotism to impel the contending parties to resort to mutual concessions for the general good. A contest so begun and so waged, could have no other termination than in the complete destruction of the one or the other of the contending bodies, or in the overthrow of both by some designing and powerful usurper, and thus in the total subversion of the constitution and the extinction of Roman liberty.

Caius Gracchus.

B.C. 123

Within the course of a few years the contest was renewed, and with more determination and energy than before, under the conduct of Caius Gracchus, the younger brother of Tiberius. During the interval that elapsed between the death of Tiberius and the public appearance of Caius, the tribunes of the people had prosecuted their endeavours to increase their own power, especially in the renewal of their tenure of official dignity. The senate managed to impede their endeavours chiefly by bestowing on them such employments as required them to be absent from Rome; and Caius himself was detained as quaestor in Sicily, even beyond the legal term of that office. Immediately on his return he was chosen tribune of the people, and forthwith resumed with double energy the enterprise of his brother. His first object was to enforce the Agrarian laws of his brother, which had hitherto been kept in abeyance, and to renew the commission appointed to survey the public lands. Being chosen a second time to the tribuneship, he procured the enactment of a law transferring the judicial power entirely from the senate to the equestrian order; and he even attempted to procure the addition of three hundred knights to the senate, for the purpose of overpowering their deliberations by the votes of his own partizans. Another of his laws provided that the soldiers should be clothed at the expense of the public, without diminution of their pay; another secured the regular distribution of corn to the poor

B.C. 122

citizens; and another proposed the granting of the privileges of Roman citizenship to all the Italian allies, as also the formation of colonies, not only in Italy, but in the provinces, and in particular at Carthage. By these popular enactments he raised himself to such a height of power in the state, that the senate did not venture to oppose him by direct means, but first endeavoured secretly to diminish his influence with the people. For this purpose they encouraged Livius Drusus, another tribune, to rival Gracchus in the race of popularity, by producing measures of a still more democratic nature, which measures the senate readily consented to pass, thinking by this deep yet base policy to weaken the power of Gracchus before attempting any more direct attack upon him. Such was the fickleness and venality of the democratic party, that they soon began to applaud Drusus above their recent leader; and when Caius stood candidate a third time for the tribuneship, he was unsuccessful. The senate saw the hour of retribution at hand, Opimius, the most daring of the aristocratic party, was elected consul, and the two factions prepared for a final struggle.

An accidental quarrel, in which Antylias, one of the consul's lictors, was killed by the friends of Gracchus, precipitated the strife. The senate conferred the dictatorial power on Opimius in the usual terms. Gracchus with his followers took possession of the Aventine hill, and attempted to open a negotiation with the consul. This was refused, and an unconditional surrender required, which not being yielded, the consul attacked the insurgents, gained the hill, and slew great numbers of them; and Gracchus himself, B.C. 121. after a fruitless endeavour to save his life by flight, fell either by his own hand, or by that of a faithful slave who accompanied him, and from whom he exacted this bloody proof of fidelity. Not less than three thousand of the friends and followers of Gracchus fell in this ill-omened struggle; and their bodies were ignominiously cast into the Tiber, as those of traitors to the commonwealth, and conspirators against its laws and government.

These contests, known in history by the designation of "the seditions of the Gracchi," shewed but too plainly that the ancient patriotic spirit of Rome had departed, never more to return. The attempt to check the growth of the already exorbitant wealth and power of the nobles had utterly failed; failed, although all legal and constitutional means had been exerted for its enforcement; failed even partly in consequence of the violent methods pursued with a view to compel its adoption; failed by being met with at least equally subtle, unconstitutional, and violent opposition; and the two antagonist powers, wealth and poverty, avarice and wretchedness, equally corrupt and unprincipled, sunk for a time into quiescence, though unreconciled, waiting but for another opportunity to burst into fiercer and more implacable hostility. The fires of the feud were not extinguished by the defeat and death of the Gracchi; they were but covered up with deceitful ashes, beneath which they smouldered scarcely observed, but acquiring tenfold strength, and preparing for an eruption which should devastate not Italy alone, but every region of the Roman world.

Within a few years after the death of Caius Gracchus, the senate not only found means to evade the Agrarian law, but also to procure its repeal; and even the land-tax which had been introduced as an intermediate step, the produce of which was to be distributed among the people, was annulled; and on the one hand, the extortion and rapacity of the nobles, and on the other, the degeneracy of the populace, proceeded with increased rapidity. Neither the authority of the censors, nor the enactment of sumptuary laws, could retard the luxuries of the wealthy; while the very means taken to support the poorer classes out of the surplus riches of the state and of great families, increased their venality, turbulence, and licentiousness.

This universal corruption of public morals was manifested in a very striking manner in the next great war into which Rome entered, which was that against Jugurtha. This crafty and far-sighted Numidian had served in the Roman armies, and made himself intimately acquainted with both the strength and the weakness of the Roman character.

Jugurthan war. B.C. 118.

Having been left joint-heir to the kingdom of Numidia, along with his two cousins, the sons of Micipsa, he resolved to sieze the whole, and procured the murder of the one, while the other fled for safety and redress to Rome. But at Rome Jugurtha's gold was more powerful than the appeals of the wronged Adherbal; and the senate decreed that the kingdom should be divided equally between the two. Scarcely had Adherbal returned to Numidia, when Jugurtha, stimulated to fresh crimes by his recently experienced impunity, declared war against his cousin, obtained possession B.C. 112. of his person, and put him to death in violation of the terms of his surrender. The tribune Memmius constrained the senate to declare war against the usurper; which was frustrated by his purchasing a peace of the consul. He was then ordered to repair to Rome, under safe conduct, to answer for his guilt. Once more was the Numidian gold too powerful for the course of justice, and Jugurtha would have been acquitted, had he not again embrued his hands in the blood of another kinsman. He was now ordered to quit B.C. 110. Rome, return to his dominions, and there prepare either to submit unconditionally, or to meet the utmost hostility of the offended and outraged republic. The war was conducted for a time with little success on the part of the Romans, till the command was entrusted to Metellus, a man of great military skill and incorruptible integrity. When this general had almost completed the conquest of Numidia, he was supplanted in the command by Caius Marius, a man of the lowest extraction, but of great abilities, courage, and force of character, and of at least equal perfidy, deceitfulness, and ferocity, who, by his popular talents, and his intriguing spirit, had got himself raised to the consulship. Marius speedily reduced Jugurtha to the necessity of taking refuge with Bocchus king of Mauritania, defeated the united armies of these two monarchs, and began to treat with Bocchus for the surrender, or rather betrayal of Jugurtha. This, however, was accomplished by Sylla, who was at that time quaestor in the army of Marius, and who so far succeeded in depriving Marius of the honour arising from the capture of Jugurtha, as Marius had done Metellus. This incident, in all probability, laid the foundation of that rancorous animosity between those two formidable rivals, which afterwards blazed out so fiercely, and spread such extensive devastation throughout the Roman dominions. Jugurtha was at length brought captive to Rome, and after being exhibited in the B.C. 106. triumphant procession of Marius, was cast naked into a dungeon, and left to perish in the agonies of hunger.

Marius.

The elevation of Marius to the consulship was an event of a very momentous character, both in itself and in its consequences. In his previous tribuneship he had shewn himself to be fully qualified to act the part of a demagogue in every respect. Being himself a person of the most obscure origin, all his habits and feelings were thoroughly adapted to those of the very lowest of the people; and yet the consciousness of great native powers of mind, gave him a certain haughtiness of bearing which could not brook control either from the senate which he braved, or the people whom he at once led and governed. Upon his appointment to the consulship, and previously to his departure for Numidia to supersede Metellus, the senate gave him little encouragement in the raising of those levies which were requisite for the vigorous prosecution of the war, being probably willing to see the popularity of the new demagogue abated, though at the expense of their country's military reputation. But Marius was not a person to be easily baffled. Instead of confining his levies to the wealthier citizens, as had always hitherto been the case, he raised it almost entirely from among the very lowest class in the state, the *capite censi*, B. C. 107. the indigent, the desperate, and the mercenary. An army formed of such materials was a fitting instrument for accomplishing any design, inasmuch as it was utterly destitute of every moral virtue and every patriotic feeling, owing no allegiance except that enforced by military discipline, or purchased by occasional indulgence in military excesses. This most unpropitious innovation secured for the time the ascendency of Marius and the popular party; but it laid the foundation of that military despotism which ultimately destroyed the last lingering remains of Roman liberty; as indeed it must do sooner or later when the military spirit becomes purely mercenary, the love of country expires, and the citizen is lost in the soldier.

This dangerous innovation might not have been so completely confirmed, had it not been for a new, and most formidable foe with which the republic was at this juncture threatened. The Cimbri and Teutones, two of those northern nations which, occasionally bursting from their forests, overran contiguous countries, exterminated the native inhabitants, and became the origin of new races and nations, had penetrated into the Roman provinces, and come into B. C. 103–109. contact with the armies of the republic. In Styria they defeated the consul Papirius Carbo; in Gaul, Junius Silanus had no better fortune; and, finally, the two consuls, Manlius and Cæpio, were routed with immense slaughter, eighty B. C. 105. thousand men perishing in the conflict. The tidings of this defeat caused the utmost consternation at Rome; and such was the military reputation of Marius, that both senate and people concurred in nominating him a second time to the consulship, even before the expiration of his first year of command. He immediately levied new forces; and in the extreme terror of the republic, no opposition was made to his enrolment of great numbers of the city populace, by which this innovation was confirmed, and the precedent established, of mustering troops from the very dregs of society, and whose character was altogether base and mercenary. For a time, however, the tide of the Cimbrian war rolled past, and spent its force on Gaul, though still continuing to threaten Italy. During this interval, Marius continued to increase his army, and to perfect the discipline of the new recruits, his tenure of the consulship being prolonged for four successive years, in consequence of the continuation of the same dread which had at first caused his illegal reinstatement in that office. In his fourth year, the Teu- B. C. 102. tones having entered the Roman territories, were defeated by Marius, near Aix, with immense slaughter, more than two hundred thousand of the invaders having perished. Next year he was equally successful against the Cimbri, in a battle fought near the Po; in which, however, his colleague Ca- B. C. 101. tulus, and, what more annoyed him, Sylla, shared the honours of the victory.

Marius had now enjoyed the consulship for the unprecedented term of five successive years, and might have retired with an unrivalled reputation; but the possession of power had only stimulated him with the eager desire of prolonging his enjoyment of it. Soon after his return to Rome he began to intrigue with the popular party, in order to obtain the consulship a sixth time, in opposition to his old rival Metellus; and having formed a strict confederacy with the tribune Saturnius, and the prætor Glaucias, two demagogues of the most unprincipled character, partly by their aid, and partly by means of the most extensive bribery, he procured his re-election to that dignity. There was now no check to the designs of the democratic faction, the people being led on by a tribune of the most abandoned and reckless character, and the senate being headed by an ambitious demagogue. But at length the extreme measures of Saturnius alarmed and disgusted even Marius; and with his usual force of character, he resolved to oppose the factious tribune. A great commotion ensued. Saturnius and Glaucias seized the Capitol, but were closely besieged, their supplies of water cut off, and being forced to surrender, they were condemned and executed as traitors. Thus did the extreme licentiousness of the popular faction compel even their own most powerful leader to interpose, and to put forth his iron strength to crush them as disturbers of the public peace, and enemies of their country.

This interposition in behalf of the republic cost Marius nothing less than a temporary loss of that power of which he was so ambitious. After the expiration of the sixth consulship, he found himself unable to retain his influence; his old antagonist Metellus was recalled from banishment; and he withdrew into Asia in a species of voluntary exile. A temporary cessation from the civil broils which had convulsed Rome, gave leisure for the reformation of the state from some of the abuses which had been forcibly introduced, or had insensibly sprung up. Some salutary laws were enacted against the systematic oppression under which the provinces groaned. Another measure, also of a reforming character, led to a less propitious result. This was an attempt to control the conduct of the equestrian order, which had become hurtful to the community, especially since C. Gracchus bestowed upon them the judicative authority. They had also obtained the farming of the leases, and consequently the collection of the revenue in the provinces, by which means they were enabled not only to oppose every reform that was attempted in the provincial administration, being judges in their own cause, but also to hold the senate itself in a state of dependence. The tribune Livius Drusus procured the enactment of a law, the effect of which was to restore to the senatorial body the half of the judicative power; but the means by which this law was passed, and by which it came into operation, involved an infringement of the constitution. Three hundred knights were added to the senate; and from the body thus raised to six hundred, the judges were selected. Unhappily this tended more and more to render the senate an aristocracy of wealth, and thus to increase the chasm, already but too wide, between the wealthy and the poor classes of the community, and to prevent the growth of a MIDDLE CLASS, one of the most fatal wants by which the republic was afflicted; a want which clearly indicated, and speedily caused, the total disruption of the social fabric.

But the most immediately disastrous subject of contention, was that which proposed the admission of all the Italian states in alliance with Rome, to the privileges of citizenship. Great numbers of the citizens of these states had either flocked to Rome upon losing their own property when conquered, or had been allured thither during the seditions of the Gracchi, by those popular leaders, with the view of strengthening their adherents, under the prospect of obtaining portions of the re-divided lands, or at least an idle maintenance from the gratuitous distribution of grain. To gratify these, and to procure a new accession of strength, Drusus proposed to admit all the Italian allies to the full rights of citizenship. This project roused the pride and the jealousy of the whole body of the people, who thought they foresaw in it the overthrow of all their peculiar privileges and powers, and who, however democratic at Rome, wished to be the aristocracy of all the world beside. The proposal was rejected by the unanimous voice of the people; and Drusus B. C. 91 himself was soon afterwards killed in a popular tumult.

The Italian states, however, were not disposed to relinquish so easily the hopes which had been thus excited. They held private intercourse with each other, interchanged hostages, and prepared deliberately for a general revolt, unless their demands should be conceded. The chief states of this social alliance were the Marsi, the Pelagi, the Samnites, and the Lucanians. Having assumed arms, the allies sent to

Social war. B. C. 91.

B. C. 88.

Rome, to demand a participation in the privileges of Roman citizens; and upon receiving a peremptory refusal, war was immediately declared against Rome. The war thus commenced, commonly termed the Social war, raged for the space of three years, the allies being as well disciplined and led as the Romans themselves; and many very sanguinary battles were fought, in which Rome sustained several severe defeats, and was for a time exposed to great danger. In this war, Cato, Marius, and the elder Pompey, greatly distinguished themselves; but the chief glory was unquestionably reaped by Sylla, who proved himself to be possessed of abilities of the very first order, equally as a politician and a warrior. The bloody struggle was at length terminated, rather by Roman policy than Roman arms. The freedom of the city was first granted to those states which had aided Rome; it was then offered to those who should first discontinue hostilities; and finally, it was given to the whole of the Italian states; so that whosoever was a citizen of any free town in Italy, became a citizen of Rome, provided he lodged his claim within sixty days after; and in this manner even many foreigners were subsequently admitted to Roman citizenship.

To counterbalance the influence of these new citizens, and to preserve to those resident in Rome itself the preponderance of political power, the new citizens were formed into only eight tribes, completing the number of thirty-five, of which they formed but a small minority, even when joined by the six turbulent city tribes. It was, however, a complete revolution, and tended to infuse a more healthy vitality into the Roman constitution, which it might have prolonged, had it not already been corrupt at the very core.

Mithridatic war.

C. 88.

Before the entire termination of the Social war, another arose in a different quarter of the world, by which the strength of Rome was severely tried. The bequest of Attalus king of Pergamus had given to the Romans extensive and wealthy dominions in Asia; and had at the same time stimulated their ambition and their avarice by the still more extensive regions which it placed almost within their grasp. The Grecian, or rather Macedonian empire had sunk before the growing power of Rome; and out of its ruins various monarchies arose, one of the most considerable of which was that of Pontus. For a time it remained tributary to its more powerful neighbours, till under Mithridates the Great, it became sufficiently strong not only to reduce the adjacent kingdoms, but even to wage an even-handed warfare against Rome itself for a number of years. Mithridates, seeing Rome weakened by the Social war, deemed it a convenient juncture to make himself master of her Asiatic dominions, and prosecuted his undertaking with such vigour and success, that he had subdued the whole of Asia Minor, and all the adjacent islands, with the exception of Rhodes, before the Romans were sufficiently at leisure to attend to his movements, occupied as they were with civil broils and social wars. But the loss of their rich Asiatic territories was what the cupidity of neither senate nor people could brook; and upon the termination of the Social war, all parties were equally eager to commence hostilities against Mithridates, anticipating vast wealth from the pillage of these opulent regions. Marius and Sylla warmly contended for the command of this important war; but the fame recently acquired by the latter in the war of the allies, enabled him to triumph over his rival. Scarcely had Sylla been nominated to the command, when fresh tumults arose in Rome, instigated by the envy of Marius, and the daring and lawless conduct of Sulpicius, tribune of the people. The object of these new tumults was to procure sufficient popular influence to remove Sylla from the command to which he had been appointed; and they were so far successful, that while he was yet in Campania with the army destined for Asia, a decree was passed in an assembly of the people, transferring the command to Marius. But Sylla's army were too much devoted to their general to submit to this capricious change. They put to death the commissioners who came to deprive him of his office; and Sylla, confiding in their adherence to him, marched directly on Rome, obtained possession of it, and put to the sword without mercy all those who had rendered themselves conspicuous by their support of his rival. Sulpicius was slain, notwithstanding the law which declared the person of a tribune inviolable; and it was with the utmost difficulty, and after sustaining innumerable hardships, and experiencing almost incredible hair-breadth escapes, that Marius himself eluded the keen pursuit of his enemies.

B. C. 87.

Sylla having thus crushed the opposite faction, and proscribed Marius, his son, and his chief adherents, re-established the power of the senate, and appointed his friend Octavius, and his enemy Cinna, to the consulship, set out against Mithridates. The relief of Greece was the first object of Sylla; and this he accomplished after taking Athens by storm, and defeating the armies of Mithridates in two great battles. Weakened and dispirited by these reverses, the king of Pontus readily concluded a treaty with the Roman general, who, on his part, was equally desirous of a peace, that he might return to Rome, where the Marian faction had regained the ascendancy.

Sylla had probably expected to produce a comparative equilibrium at Rome, by the appointment to the consulship of one from each of the contending factions. Here, however, his policy failed, probably from being too refined, or from his not taking into consideration the new element which had been introduced, by the admission of the Italian states to the citizenship. He had in a great measure exterminated the democratic party in Rome itself, and restored the power of the senate; but Cinna perceived the means of raising a powerful body of new adherents, by proposing to throw open all the tribes to the Italian states, which would have given them a preponderance in every popular assembly. This the other consul, Octavius, opposed; and Cinna was compelled to withdraw to the country, where he soon mustered a powerful army of the disaffected allies. Marius, who had fled to Africa, being informed of the turn which affairs had taken at Rome, conceived hopes of recovering his power, and immediately returned to Italy, joined Cinna, and at the head of an immense horde of robbers and semi-barbarians, the very dregs of the populace of all Italy, who flocked to his standard from all quarters, advanced against the city. At his approach Rome was thrown into consternation; and there not being any forces sufficient to oppose him, the senate offered to capitulate, on condition that the lives of the opposite party should be spared. During the progress of these negotiations, Marius entered the city at the head of his armed and barbarous adherents, secured the gates that none might escape, and gave the signal for slaughter. On rushed his barbarians like wolves, sparing neither age nor sex, while Marius gazed on the horrid scene with grim and savage delight. During five days and five nights, the hideous massacre was continued with relentless ferocity, while the streets were deluged with blood, and the heads of the murdered victims were exhibited in the Forum, or laid before the monster himself for his peculiar gratification. At length Cinna grew sick of the protracted butchery; but the barbarians of Marius could not be restrained till they were themselves surrounded and cut to pieces by Cinna's soldiers.

B. C. 86.

Having gratified his revenge with this bloody butchery, Marius nominated himself consul for the seventh time, and chose Cinna to be his colleague. This he did without the formalities of a public assembly, as if to consummate his triumph over the liberties of his country, thus trampled upon by an act at once of violation and of insult. But a short time did he enjoy his triumph and revenge. In the seventeenth day of his seventh consulate, and in the seventieth year of his age, he expired, leaving behind him the character of having been one of the most successful generals, and most pernicious citizens of Rome.

Sylla.

Sylla having concluded a treaty with Mithridates, returned at the head of his victorious army, prepared and determined to inflict the most signal and ample vengeance upon the Marian faction, whom he deemed equally foes to himself and to the republic. Before his arrival in Italy, Cinna had been killed in a mutiny of his own troops; and none of the other leaders possessed talent and influence enough to make head against him. After a short but severe struggle, Sylla prevailed, and immediately commenced his dreadful, deliberate, and systematic course of retribution. All who had either taken part directly with Marius, or who were suspected of attachment to the democratic party, were put to death without mercy, and, what was almost more terrible, apparently without wrath. Sylla even produced publicly a list of those whom he had doomed to death, and offered a reward for the heads of each. He thus set the example of proscription which was afterwards so fatally imitated in the various convulsions of the state. His next step was to depopulate entirely several of those Italian states which had joined the Marian faction, and to parcel out the lands among his own veteran troops, whom he thus at once rewarded and disbanded in the only manner likely to reconcile them to peaceful habits. Having thus satiated his revenge, his next care was to reform and re-construct the constitution and government of the state, shattered to pieces by long and fierce intestine convulsions. He caused himself to be appointed dictator for an unlimited time. He restrained the influence of the tribunes, by abolishing their legislative privileges, reformed and regulated the magistracy, limited the authority of governors of provinces, enacted police regulations for the maintenance of public tranquillity, deprived several of the Italian states of their right of citizenship, and having supplied the due number of the senate by additions from the equestrian order, he restored to it the possession of the judicative power.

Having at length completed his career as a political reformer, Sylla voluntarily resigned his dictatorship, which he had held for nearly three years, declared himself ready to answer any accusation that could be made against him during his administration, walked unmolested in the streets as a private person, and then withdrew to his villa near Cumæ, where he amused himself with hunting and other rural recreations. Whether his retirement might have remained long undisturbed by the relatives of his numerous victims, cannot be known, as he died in the year after his abdication of power, leaving, by his own direction, the following characteristic inscription to be engraved on his tomb: "Here lies Sylla, who was never outdone in good offices by his friend, nor in acts of hostility by his enemy."

B.C. 78.

The civil wars between Marius and Sylla may be considered even more worthy the careful study of the historian, than those between Pompey and Cæsar, for a right understanding of the circumstances which led to the destruction of Roman liberty, as the latter but concluded what the former had begun. Indeed, the strife between Marius and Sylla was itself the natural sequel of that contest between the aristocratic and the democratic factions, if they ought not rather to be termed the factions of wealth and poverty, which gave rise to the sedition of the Gracchi, and which being conducted on both sides with no spirit of mutual concession, none of mutual regard for the public welfare, deepened into the most bitter and rancorous animosity, such as could end in nothing but mutual destruction. Of the worst spirit of democracy, we see in Marius what may be called a personification; fierce, turbulent, sanguinary, relentless; brave to excess, but savagely ferocious; full of wily stratagems, in order to gain his object, then dashing from him every hard-won advantage by his reckless brutality. On the other hand, the aristocratic spirit had its representative in Sylla; haughty, cautious, and determined, forming his schemes with deep forethought, prosecuting them with deliberate perseverance, and abandoning them with cold contempt when his object was accomplished. He held his dictatorial sway till he had satiated his revenge, and re-established, as he thought, the government on an aristocratical basis, then scornfully laid aside his power, and yielded himself to voluptuous indulgence. By these men it was made clearly evident that Rome no longer possessed sufficient public or private virtue to maintain her republican institutions; that she was tottering on the very brink of a complete and final revolution, leading with fatal certainty to a military despotism; and the only question was, whether her despotic ruler should be a Marius or a Sylla; whether he should spring from among the democratic populace, or the aristocratic nobility; a question not long to be left in doubt.

Many of the laws enacted by Sylla were of a very wise and beneficial character, though their general aim was too manifestly the restoration of aristocratic power to the senate. What effect his personal influence, had his life been prolonged, might have had in consolidating his political reforms, cannot certainly be known, though it may very safely be conjectured that not even his power could long have prevented new convulsions. The malady lay too deep to be reached by any merely political measures of a remedial nature. It had its essence in the degeneracy and moral turpitude of the entire body of the republic, both nobles and people, which there was nothing in their external circumstances to prevent, or in their national religion to heal. Besides, as in the recent wars and revolutions, almost all property had experienced a change of possessors, there were vast numbers throughout all Italy eager for a counter revolution. Several young men also of abilities and ambition, were prepared to emulate the career of Marius or of Sylla, which could not be done without a renewal of that contest, the heavings of which had not yet wholly subsided. Of these, the chief were Lepidus, Crassus, Pompey, and Sertorius, and perhaps Lucullus.

Lepidus

Very soon after the death of Sylla, the consul Lepidus, made an attempt to rescind the laws of Sylla. In this he was opposed both by his colleague Catulus, and by Pompey, who was now the head of the aristocratic party, to which he had attached himself before its final triumph over the Marian faction. Lepidus was declared a public enemy, defeated in battle, fled to Sardinia, and there died.

Sertoriu

A more dangerous and protracted contest was waged in Spain, to which country Sertorius had withdrawn, and gathered around him the relics of the Marian party. For six years did this virtuous and heroic republican maintain a successful struggle against the whole power of Rome, defeated successive consular armies, and baffled even the experience of Metellus, with the skill and energy of Pompey. At length he was basely assassinated by Perpenna; and upon the loss of their leader, his forces were easily subdued by Pompey, and Spain was reduced to obedience.

B C. 7

War of
gladia

Before the termination of the Spanish war, one still more dangerous commenced in the very heart of Italy. Spartacus, a celebrated gladiator, a Thracian by birth, escaped from the gladiatorial training school at Capua, along with some of his companions, and was soon followed by great numbers of other gladiators. Bands of desperate men, slaves, murderers, robbers, pirates, flocked to him from all quarters; and he soon found himself at the head of a force able to bid defiance to Rome. Four consular armies were successively defeated by this daring adventurer, and Rome itself was considered in imminent danger. But subordination could not be maintained in an army composed of such materials. Spartacus purposed to march into Gaul, invite Sertorius to join him, and then together march on Rome. Had this plan been carried into effect, Rome in all probability must have fallen into the hands of the combined forces; but the tumultuous followers of Spartacus, longing for the pillage of the capital, compelled their leader to abandon his intention, and bend his course towards that devoted city. He was met and completely routed by the prætor Crassus, who thus acquired some renown in war, in addition to the influence which he possessed from his unequalled wealth. Pompey, on his return from Spain, encountered and destroyed several scattered bodies of the gladiatorial army; and thus, with his usual good fortune, obtained a claim to divide the honour with Crassus. From this period, these two powerful individuals cherished sentiments of envious rivalry against each other, the effect of which proved ruinous to the commonwealth.

B.C. 71.

Crassus.

The enormous wealth of Crassus enabled him to purchase the support of the people, by bestowing upon them large donations of money and corn. To counterbalance his influence, Pompey, although attached to the aristocratic party, proposed the repeal of some of Sylla's laws, and the enactment of others of a more popular character; in particular, the restoration of the powers and privileges of the tribunes. By these means he so ingratiated himself with the people, that, with powers never before entrusted to any general, he obtained the command of the armament prepared against the pirates by which the seas were so greatly infested. In this war he distinguished himself in a very remarkable manner, by his skill, courage, and activity, and raised himself to a height of power and of military fame, at that time beyond all rivalry.

Lucullus.

During the progress of these events in Spain and Italy, Mithridates had renewed the war in Asia Minor. Lucullus, to whom the command in the Mithridatic war was now given, defeated the fleet of the Pontic king, relieved Cyzicus, and overthrew the combined forces of Mithridates and Tigranes in two great battles, bringing the struggle to the very brink of a successful conclusion. But the mutinous spirit of his own army, and the hostility which he aroused against himself, by his reform of the financial administration of the provinces, occasioned his recall. Pompey was next appointed to the command of the armies in Asia; and thus again was he favoured by fortune to obtain the crowning glory of a victory already all but won. Mithridates finding all his efforts ineffectual, and being in danger of immediate captivity from the defection of his son-in-law, Tigranes, and the treason of his own son, Phraates, killed himself, that he might not fall into the hands of the Romans. After the conclusion of the war, Pompey spent some time in Asia, settling its affairs, and arranging it into different provincial districts. By the fall of Mithridates, and this settlement of Asiatic affairs, the republic may be considered to have reached the highest pitch of her power; but when the summit has been gained, the next step is inevitably downward. The very existence of the republic, as such, now depended, partly upon the caprice or the moderation of Pompey himself, partly upon the judicious or the erroneous measures which Crassus might adopt, in his endeavours to counterbalance the power of his mighty rival.

B.C. 63.

Pompey.

Unfortunately for Rome, the two rivals saw no better method of maintaining each his own influence in opposition to that of his antagonist, than by separately or jointly courting popularity. Pompey had led the way in this injudicious procedure, by his partial restoration of the tribunitian power; and this restoration was completed by the joint influence of him and Crassus during their united consulship. It had been found by ambitious men, that they could not obtain their objects of pursuit, whether those objects were chiefly aristocratic or democratic, without becoming demagogues; and therefore unhappily it was considered by them necessary to re-establish in all its power an office, of which the very nature pointed it out for such a pernicious abuse. But as extremes in all things meet, these very demagogues necessarily became an oligarchy; and while they pretended to promote the interests of the people, such men as Pompey and Crassus engrossed the whole powers and emoluments of the state.

Cataline's conspiracy.

Before this rivalry had reached its crisis, and during the absence of Pompey in Asia, Rome was threatened with a new convulsion, and new competitors for public favour began to appear on the scene. Lucius Sergius Catilina, a young man of noble birth, but of desperate fortunes, and of the most depraved character, formed a conspiracy to destroy the chief men of the state, seize on all public property, restore the Marian faction, and, placing himself at its head, to invest himself with supreme power. Not only the profligate of the youthful nobility, and the indigent of the populace, joined in this conspiracy, but even Crassus and Julius Cæsar were accused of having been so far implicated in it. After several failures and postponements, the conspiracy was partly detected, and partly forced into a premature disclosure by the failure of Cataline in his attempt to obtain the consulship, and the prudent preventive measures of his successful rival, Cicero, who also at that time began to act a distinguished part in public affairs. Not all the daring, nor all the secret attempts of Cataline could overawe, or elude the energy and vigilance of Cicero; and at length the desperate and baffled conspirator fled from the city, and raised the standard of revolt in Etruria. His associates in Rome were seized and put to death, and he was himself defeated and slain in a desperate battle, after having performed deeds of the most determined valour. So highly had Cicero distinguished himself by his detection and suppression of this dangerous conspiracy, that the senate unanimously bestowed upon him the honourable title of *Father of his Country*.

Cicero.

B.C. 62.

Cato.

Cæsar.

During the progress, and in the suppression of this conspiracy, several very remarkable men had come prominently forward. These were Cicero, unmatched for eloquence, learning, and philosophical wisdom; Cato, a true republican of the ancient mould, simple, severely virtuous, and uncompromising; and Cæsar, unrivalled in the versatility, extent, and power of a genius, equally fitted to attain preeminence in the pursuits of literature, philosophy, politics, and war. The two former adhered to the aristocratic party in the state, who were headed by Pompey; the latter made the democratic party the basis of his power, although he was himself descended from one of the most ancient and noble families of Rome. He had the address both to extricate himself from the conspiracy of Cataline, and to make himself at the same time the person to whom the survivors of that party looked for protection. From that period it was evident, that whatever might be the destinies of Rome, Cæsar must exercise a potent influence over them, for evil or for good.

The return of Pompey from Asia caused a renewal of the contest for power between that general and the party which sought to maintain the independence of the senate. Of this party, Cato, Lucullus, and Metellus, were the chief adherents; but their efforts only caused Pompey to throw his influence more into the popular scale, and thus unconsciously to promote the ambitious views of Cæsar. That sagacious man, perceiving the necessity of acquiring both the skill and the renown of a general, and having hitherto in a great measure abstained from military affairs, got himself appointed to the governorship of Lusitania, where he soon acquired a high reputation for warlike talents, and at the same time repaired his dilapidated fortunes.

During the absence of Cæsar, the contest between Pompey and Crassus continued, each endeavouring to weaken the influence of the other; and the independent party in the senate, led by Cato, and occasionally aided by Cicero, availing themselves of this struggle to diminish the undue power

B. C. 59.

of both. But upon the return of Cæsar, this contest was brought to a termination. The two rivals began to perceive that their power was in danger of being equalled, if not surpassed by a third; and Cæsar, to lull their jealousy asleep, till his own designs should be matured, pointed out to them the risk they incurred of merely ruining each other, if they did not speedily compose their differences. He at first paid most court to Pompey, as his most formidable rival, and affected devotion to his cause, till by his aid, seconding his own rising fame, he procured the consulship. During his tenure of that office, he still more increased his popularity by the enactment of several salutary laws, and some of more ambiguous character. In particular, he carried an Agrarian law for the distribution of large tracts of land in Campania among the indigent people, and had the address, in spite of the opposition of the senate, to induce both Pompey and Crassus to aid him in passing it, and to act as commissioners in the distribution, thus sharing the odium of the measure, while the entire popularity remained his own.

The first triumvirate.
B. C. 59.

The schemes of Cæsar required a new element for their further development. He well knew that he could not gain the supreme power without an army to support his pretensions, or depend on an army without having previously made it completely his own. It was therefore necessary for him to obtain the command of a warlike province, and that, if possible, adjacent to Rome. Gaul was exactly suited to his purpose; and he now directed his efforts to the obtaining of that appointment. Neither Pompey nor Crassus seems to have penetrated his views; and a secret but strict alliance was formed between these three powerful and ambitious men, commonly known by the name of "the first triumvirate." The province of Gaul was allotted to Cæsar for a term of five years, while Pompey and Crassus remained at Rome; and the compact between Cæsar and Pompey was confirmed by the latter marrying the daughter of the former.

To complete the triumph of the triumvirs over the independent party in the senate, Cato was appointed to the government of Cyprus, and Cicero was banished through the intrigues of the infamous Clodius, who had obtained permission to relinquish his patrician rank, that he might be eligible for the tribuneship; an example which was afterwards repeatedly followed by designing demagogues. After having accomplished this object, Clodius became so troublesome even to his own party, that to keep him in check, Pompey procured the recall of Cicero from exile, which he could not effect without the strenuous aid of the tribune Milo.

In the mean time, Cæsar had arrested the migration of the Helvetians, expelled the Germans from Gaul, subdued the Belgæ, the Aquitani, the Nervii, and other warlike Gaulish nations, and had also both penetrated into Germany itself, and crossed the sea to Britain, till then almost unknown to the Romans. By these exploits he raised his military reputation to an equality with that of Pompey himself, and formed a hardy and well-disciplined veteran army, entirely devoted to his will. Nor was he inattentive to the course of events at Rome. He found means to maintain his influence there to such a degree as to rouse the dormant jealousy of his rivals, and almost to precipitate the struggle. A reconciliation, however, took place; and he obtained a renewal of his command in Gaul for another term of five years, while Crassus chose Syria for his province, and Pompey Spain and Africa. Crassus appears to have chosen Syria for the purpose of gratifying his passion for the acquisition of wealth; and Pompey preferred those provinces which he could govern by his lieutenants, while he remained at Rome to rule the republic.

B. C. 5

This new arrangement was not destined to a lengthened existence. On his arrival in Asia, Crassus found himself compelled to enter into hostilities with the Parthians, to whose vicinity the overthrow of Mithridates had extended the sway of the republic in that continent. Even to the best of the Roman generals, the Parthians would have proved a formidable foe; but Crassus was altogether destitute of the military talents necessary for the conduct of such a war. His army was entirely routed in Mesopotamia, and himself taken prisoner and put to death soon after the battle, by the Parthian general Surena.

About the same time died Cæsar's daughter, the wife of Pompey; and thus not only was the triumvirate dissolved by the death of Crassus, but the alliance between the two survivors was greatly weakened by the death of Julia, who had possessed considerable influence over both her father and her husband. The period for the termination of Cæsar's command in Gaul had nearly arrived; and all things seemed to indicate the approach of a mortal crisis.

Each party strove to throw on his rival the odium of beginning the fatal contest; and its actual commencement was for a time retarded by their mutual machinations. At length it began by Cæsar's demanding permission to hold the consulship while absent. This was strenuously opposed by Pompey, and advocated by Cæsar's partizans, Curio, Marcus Antonius, and Quintus Cassius, tribunes of the people. Curio succeeded in placing Pompey in what is termed, "a false position," by proposing that both he and Cæsar should resign their offices and retire into private life, which he averred that Cæsar was willing to do. Repeated but insincere offers were made by both parties for an accommodation; but the senate at length passed a decree, commanding Cæsar to disband his army before a certain specified day, under the penalty of being declared a public enemy. The two tribunes, Antony and Cassius, interposed their veto; but their prerogative was violently set aside, and the decree passed by a large majority. Upon this Antony and Cassius fled from the city disguised as slaves, and sought refuge in the camp of Cæsar, who shewed to his soldiers the tribunes thus insulted by his enemies at Rome.

Civil wa

B. C. 49.

The conduct of Cæsar had hitherto appeared to be chiefly defensive, that of Pompey and his party aggressive. It had now become necessary for Cæsar either to relinquish his long-cherished visions of ambition, or to become the assailant. He had completely foreseen and anticipated the crisis. At the head of but a small division of his army, not sufficient to create alarm, he had approached the banks of the Rubicon, the boundary of Italy proper, on the side of Cisalpine Gaul, and which he could not cross in a hostile manner without avowing himself a traitor to his country. His schemes were ripe for execution, his enemies were thoroughly roused, concealment was no longer practicable, his troops had declared their readiness to support their general and avenge the wrongs of the tribunes, all things urged him to the crisis; but the dark destinies of the fateful hour hung heavy upon Cæsar's spirit.[1] He retired early from a supper where he had entertained some of his principal officers, and paced to and fro on the banks of the Rubicon, in the deep silence of midnight, oppressed with thought. It probably was not the ruin to himself, should he now hesitate, still less the perils of the undertaking; it was the long, black, direful train of miseries that must sweep remorselessly over his country and the world, all summed up, concentrated, and rendered almost visibly present in the one simple and brief act of that most awful hour, this it was that shook and appalled the heart of even the mighty Cæsar. He at length exclaimed, "the die is cast," sprung furiously across the slender stream, and spread to the morning breeze the banner of civil war.

---

[1] See Suetonius in Vita Jul. Cæs.

Before the close of that day Ariminum was seized by Cæsar. With the speed of a torrent, and the gathering strength of an Alpine avalanche, he advanced on Rome. City after city opened its gates at his approach, their garrisons swelling the number of his troops. Pompey and his party were paralyzed by his boldness, and terror-struck by the celerity of his movements. They abandoned the city and fled to Capua, leaving the public treasure behind them. Thence they fled to Greece, without daring once to turn upon their swift pursuer. Corfinium alone seemed disposed to make a show of resistance; but the garrison declared for Cæsar, and their commander, Domitius, surrendering at discretion, was treated with the kindness due to an honourable foe. Cæsar then retraced his course to Rome, and entered it without opposition, having subdued all Italy in sixty days. He assembled such members of the senate as had remained in the city; declared himself driven to hostilities by the machinations of his enemies, yet still a friend to the republic; seized upon the funds in the public treasury, and after a short delay of six days, set out to attack Pompey's lieutenants in Spain.

In his march through Gaul he was joined by his veteran troops, at whose head he had gained so much glory, and whom he had doubtless been training for that enterprise in which he was now engaged. On his arrival in Spain he began a series of manœuvres surpassed by nothing in the history of war, for the purpose of compelling Afranius and Petreius, not to a battle, but to a capitulation of their entire army, which he wished thus to preserve and make his own. This he at length accomplished; and on his return through Gaul reduced Massilia, which had till then held out against him. But these successes, where he commanded in person, were somewhat counter-balanced by some severe defeats sustained by his generals in Illyricum and Africa.

Returning victorious to Rome, he was named dictator, a title which he soon afterwards exchanged for that of consul; and after spending a short time in the arrangement of public affairs, he prepared to sail for Greece, in order to bring the struggle to a close, by encountering his great rival in person. Pompey had assembled an immense army, drawn from the various Asiatic states where Roman troops had been stationed; and his camp was dignified by the presence of great numbers of the fugitive senate. Cæsar with much difficulty and danger transported his army from Brundusium to the vicinity of Dyracchium, where Pompey was encamped. For some time the contest between these two great generals was a war of tactics, each endeavouring to out-manœuvre his antagonist, before putting the final issue to the hazard of a decisive battle. As Pompey's fleets had the command of the sea, he was enabled to act on the defensive, without the danger of falling short of provisions, to which Cæsar was much exposed. Cæsar therefore used his utmost efforts to draw his adversary to a general engagement; in which he had almost succeeded, when he was himself surprised, one division of his army thrown into confusion, and the whole so greatly endangered, that nothing but the most desperate efforts made by himself in person, prevented a total rout.

Soon after this hazardous encounter Cæsar withdrew from Dyracchium, and marched to Thessaly, where he had better access to both provisions and reinforcements. He was followed by Pompey, who still abstained from battle, hoping to exhaust his foe. But this wary policy of Pompey was disliked by the young nobility, who longed for the fight, especially since their partial success at Dyracchium. At length Pompey drew out his army on the plains of Pharsalia, and offered Cæsar the opportunity which he had so long sought, of deciding the empire of the world. In this great battle the superior skill of Cæsar was manifest. Being deficient in cavalry, in which the strength of Pompey's army lay, he altered the usual form of drawing up the army in three lines, placing a fourth in reserve for the support of his cavalry, with particular directions how to act. When the signal was given, the troops of Cæsar rushed on with their usual impetuosity; those of Pompey stood still to receive the shock. The cavalry of Pompey at first repulsed that of Cæsar; but being unexpectedly assailed by the reserve, they were thrown into confusion, and fled, leaving the flank of the main body exposed, which was instantly assailed by Cæsar's victorious wing. This decided the fate of the day. Pompey's legions were thrown into irretrievable confusion, driven to their camp, the entrenchments carried by storm, and the whole either scattered over the country, or compelled to surrender at discretion. Cæsar finding the victory secure, hurried from place to place across the bloody field, calling aloud to spare the Roman citizens; and all who yielded were treated with the utmost clemency.

tle of
rsalia.
C. 48.

Pompey, as if bereft of his usual courage and presence of mind, made no effort to retrieve the fortunes of the day. He at first retired to his camp, and when its entrenchments were forced, he fled in disguise from the scene not more of ruin than of disgrace. He directed his course to the Ægean sea, purposing to renew the war in Syria; but finding the Asiatic states not inclined to support what they now deemed a falling cause, he altered his plan, and steered for Egypt, having taken on board his wife Cornelia. When he drew near the Egyptian shore, he found the young king besieging Pelusium, and sent intimation of his approach, and of his intention of joining his forces with those of Egypt. The perfidious Egyptians resolved to allure him on shore, and then put him to death, as the safest mode of escaping the danger of his own resentment, if they should refuse him succour, or that of his rival, if they should grant it. Achillas, the commander of the Egyptian forces, and Septimius, a Roman soldier who had formerly served under Pompey, proceeded in a boat to the galley to conduct him to land. He left his vessel with strong forebodings of what might follow; and as the boat drew near the shore, Septimius stabbed him in the back, and the others falling upon him, completed the treacherous and bloody deed. The galley in which he came had anchored so near the shore, that the murder of Pompey was distinctly visible to those on board. The wild shriek of anguish raised by Cornelia as she beheld her beloved husband fall, reached even to the shore; and on the instant, the Roman galley cutting her cable, and putting to sea, escaped the pursuit of the Egyptians. Thus perished Pompey the Great, a fugitive and alone on a barbarian shore, after having held for many years a scarcely divided sway at Rome, which he failed in making his exclusively and permanently, only because his rival and antagonist was Cæsar.

Death of Pompey.

Immediately after his victory at Pharsalia, Cæsar commenced a close pursuit of Pompey, knowing that the war could only end with his death or captivity. Tracing the course of his defeated rival's flight, he arrived at Alexandria, where he not only received the tidings of his death, but the Egyptian messengers laid before him the head and ring of Pompey. From these melancholy memorials of his mighty rival Cæsar turned away with strong shudderings, and with bursting tears of pity; and gave orders that near Pompey's tomb, a magnificent temple should be erected to Nemesis. He next employed himself in settling the disputed claims for the succession to the Egyptian throne, which he bestowed on the celebrated Cleopatra, influenced more by the beauty of her person than the superiority of her pretensions. While in Egypt, he was exposed to great danger, from an insurrection of the dethroned king's partisans; but the opportune arrival of his forces enabled him completely to subdue it, and to establish the sovereignty of Cleopatra. From Egypt he marched into Asia, against Pharnaces, son of Mithridates the Great; and in the short space of thirty days, completely annihilated his army, and subdued his dominions. It was in giving an account of this brief war, that he used the famous words, *Veni, vidi, vici.* "I came, saw, conquered."

During Cæsar's delay in Egypt, and expedition into Pontus, great disturbances had broken out in Rome; to remedy which he repaired thither with his usual promptitude and speed. Upon his arrival, he was again nominated dictator, and strenuously applied himself to the reform of the abuses which had been committed in his absence by ill-judging and intemperate partisans. No proscriptions followed his arrival, no blood was shed, no injustice perpetrated; and this clemency, so different from the conduct of Sylla and Marius, induced numbers of the most distinguished men of what had been the independent party in the senate, to return to Rome, and there to renew the semblance of a regular form of government. He then turned his attention to Africa, where a strong body of his antagonists had been drawn together by Cato and the sons of Pompey. The struggle was severe, but not protracted. A decisive battle was fought at Thapsus, where the Pompeian party were completely overthrown. Despair filled the hearts of the routed leaders. Cato died by his own hand in Utica; Scipio, being intercepted in his flight, stabbed himself and fell into the sea, while Cæsar's men were boarding his galley; and Juba, king of Numidia, and his general Petreius, fell by each other's hands in single combat. The two sons of Pompey escaped and fled to Spain, where they endeavoured once more to rekindle the embers of the expiring war.

B. C. 46.

Upon his return victorious from Africa, Cæsar was received at Rome both by senate and people with great adulation, and he celebrated his triumph with uncommon pomp and splendour. He was again created dictator for ten years, and honours were heaped on him with lavish hand. Again did he renew his acts of clemency and generosity to all who had been opposed to him, thus confirming his popularity and consolidating his power.

But Pompey's sons, Cneius and Sextus, having collected a considerable force in Spain, Cæsar found himself once more obliged to quit Rome. The two armies met in the plains of Munda, and prepared for the final struggle with all the energy of hope on the one side, and on the other of despair. So furious was the conflict, that Cæsar was compelled to put himself at the head of his favourite tenth legion, and to fight as a common soldier, not for victory merely, but for life. Victory at length declared for him; a vast number of his most eminent and determined enemies fell in the battle, or in the flight, and among the latter was the eldest son of Pompey. With this sanguinary conflict the war was at once terminated, and Cæsar returned in full triumph to Rome.

B.C. 45.

Having now completed the subversion of the republic, Cæsar assumed the undivided sway of Rome, although he tolerated the continuation of the forms of republican government. In his own person he concentrated those offices which were requisite for the conduct of public affairs, such as the dictatorship, the consulate, and the offices of tribune, censor, and pontifex maximus. Thus possessed of all authority and power, he commenced a number of reforms, improvements, and public works of utility, which did honour to his genius, his judgment, and his spirit of enterprise. He reformed the calendar, and undertook to drain the Pontine marshes, to deepen the channel of the Tiber, to form a capacious harbour at Ostia, to cut a canal through the isthmus of Corinth, and to revenge the defeat of Crassus, by an expedition against the Parthians. In the midst of these schemes and undertakings he gave offence to the senate by his haughtiness, and to the people by his too evident assumption of regal dignity, and almost of the regal title. They could better brook the loss of liberty in reality than in appearance; they retained their love of the form of the republic, when its spirit was gone; they could not endure the name of king, while they were willing to submit to real monarchy under the name of a perpetual dictatorship.

Influenced by these feelings, a large body of the senators began to regard Cæsar as an usurper, and many even of the people, who had formerly supported him as their leader against the aristocratic party, became also disaffected. Mark Antony's offer of a crown at the feast of the Lupercalia, put forth in all probability for the purpose of ascertaining the bias of the popular mind, was met by such decided disapprobation, as to cause Cæsar himself to hesitate, and to wait for a more propitious juncture for the completion of his designs. Meanwhile, a conspiracy was formed for his destruction, and at the head of it were Brutus and Cassius, who had both experienced his clemency and additional marks of his favour. After having narrowly escaped detection, they resolved to strike the blow in the senate-house itself, on the ides of March. No sooner had he taken his seat than the conspirators crowded round him, preferring various requests, and one of them, apparently in extreme urgency, seized him by the robe. At this preconcerted signal, they all rushed upon him with their daggers, and Cæsar, perceiving resistance fruitless, muffled up his head in his mantle, and fell at the base of Pompey's statue, pierced by three-and-twenty wounds. At this moment, Brutus waved aloft his bloody dagger, hailed the senate, and in particular Cicero, and proclaimed aloud the recovered liberty of Rome.

Death
Cæsar.
B. C.

But instead of joy and gratitude, a general terror pervaded the senate and the citizens. They had felt secure in the well-known clemency and the settled power of Cæsar; they knew not what scenes of anarchy and bloodshed might follow his death, nor what might be the temper of his successor in the chief power. A dull dead calm brooded over the city for some days; till, on the day of Cæsar's funeral, Antony inflamed the smouldering passions of the populace to such a degree, that they burst into the senate house, tore up its benches, and raised an immense funeral pile for the body, sacked in their fury the houses of the conspirators, and wreaked their vengeance on all of that party whom they could seize. Alarmed by these proceedings, the chief conspirators fled from the city, and prepared to vindicate their deed, and defend the republic by arms.

Previously to this tumult, Antony had concurred with Brutus and Cassius in passing an act of amnesty, granting forgiveness to all who had been implicated in any of the former proceedings. But having stirred up the populace, and being joined by Octavianus, or Octavius, the grand-nephew and heir of Cæsar, he now entered boldly on his turbulent and ambitious career. Brutus and Cassius retired to Macedonia and Syria, to which provinces they had been appointed, leaving Italy in the power of Antony and Octvaius. A jealousy soon arose between these two leaders of the revolutionary party; and Octavius joining the senate, Antony retired into Gaul, raised an army, and came to an engagement with the two consuls near Mutina, where he was defeated, but both the consuls fell in battle. Antony fled to Spain, and joined Lepidus; but before renewing the war, he represented to Octavius that their hostilities would only secure the triumph of the senate and the conspirators. In consequence of this suggestion, Octavius, Antony, and Lepidus, came to an interview in a small island in the river Lavinus, not far from the modern city Bologna, and there formed a confederacy, called the "second triumvirate." In the course of their proceedings, these three ruthless men drew up a list of those whom they wished to be put to death, each, without compunction, permitting relation or friend to be proscribed, if required by the others. This bloody proscription was followed by the murder of not less than 300 senators, and 2000 of the equestrian order. Among the former was the illustrious Cicero, whose death was occa-

Second triumvirate.
B C. 43.

sioned by his invectives against the dissolute and infamous Clodius, and the unprincipled and tyrannical Antony.

tle of lippi. C. 42.

Soon after the formation of this blood-cemented compact, Octavius and Antony prepared to wage war against Brutus and Cassius, who had combined their forces, and were in Macedonia. The rival armies met near Philippi; and two separate battles were fought before the victory was decided. In the first, the division commanded by Cassius was defeated; and he, thinking the battle lost, slew himself in despair. Brutus, however, had been victorious with his division; and the two antagonist armies, rallying each on its unbroken half, remained ready for another trial of strength. This took place within about twenty days after the first, and on nearly the same ground. The struggle was fierce, obstinate, and bloody; but at length the troops of Brutus gave way, fled, and were scattered in total rout and dismay. Brutus, disdaining to survive this, the last convulsive effort of the republic, fell on his own sword, and died. The conduct of Octavius and Antony, after their victory, bore a greater resemblance to that of Sylla and Marius, than of Cæsar, whose memory they would have more honoured by imitating his clemency, than by a bloody revenge of his death.

The utter ruin of the republican party was followed by a period of disgraceful intrigues, jarrings, and contests, among the usurpers, and their corrupt friends and followers. Antony traversed Greece, and part of Asia, luxuriating in the pomp, the homage, the flatteries, and the voluptuousness of the East. At one time he meditated a war against the Parthians, to redeem the fame of Rome, which had been tarnished by the defeat of Crassus; but meeting with Cleopatra, he abandoned his dreams of glory, and resigned himself to the debasing delights of loose licentiousness, beneath the syren spell of this abandoned beauty.

Octavius, on the other hand, returned to Italy, and prosecuted his deep-laid schemes for securing the sole possession of despotic power. He was repeatedly disturbed by the intrigues and the violence of Lucius, the brother, and Fulvia, the wife, of Antony; but at last, the rupture having come to an open war, they were defeated; their chief strength, Perusia, was taken, and Octavius secured in the undisturbed command of Italy. The tidings of this contest drew Antony from Egypt, and a war between him and Octavius seemed on the point of breaking out. At this juncture Fulvia died; and instead of a war, a new alliance was formed between the jealous triumvirs, Antony receiving in marriage Octavia, the sister of Octavius. In this new division of the Roman dominions, Sextus Pompey was admitted to a participation.

C. 39.

But their hollow agreement was of no long duration. New jealousies arose between Octavius and Lepidus, and new wars with Pompey. Being defeated by Octavius, Sextus Pompey fled to Asia, and was there slain by one of Antony's lieutenants. Lepidus was soon afterwards deprived of his share in the triumvirate; and Antony and Octavius divided the whole power between them. Little cordiality subsisted between these partners, or rather rivals; but a decided quarrel was delayed in consequence of their distance from each other, and the different regions in which they sought for an extension of fame and dominion. Antony was still desirous of triumphing over the Parthians, but he met with little success, except where his troops were led by Ventidius. Octavius found employment for his legions in Dalmatia and Pannonia, into which the arms of Rome had scarcely before penetrated. At length the conduct of Antony thoroughly disgusted all his friends at Rome. Octavia set out for the East, hoping to recall her husband to some sense of his duty to Rome, to her, and to himself; but the infatuated man, unable to break through the fascinations of Cleopatra, refused to see Octavia, ordered her to return home, and even sent her a divorce. This insult Octavius could not brook. Antony was deprived of his consulship by a decree of the senate, and both parties prepared for another war.

Battle of Actium. B. C. 31.

Mutual jealousy had long anticipated such a contest, and they were both in readiness at once to rush to the arbitration of arms. The forces of Antony were the more numerous; those of Octavius the better disciplined, and led by generals of great skill and judgment. Their armaments, both military and naval, came within sight of each other on the opposite sides of the entrance to the gulf of Ambrasia in Epirus. For some time they remained comparatively inactive, watching each other's movements. At length the two hostile fleets met off the promontory of Actium, that of Octavius led by Agrippa, that of Antony by himself and Cleopatra. The battle began, in sight of the land forces on either side, and was continued with equal courage and fortune, till Cleopatra, terrified by the dreadful scene, turned her galley and fled, followed by sixty of the Egyptian vessels, and soon after by Antony himself. The deserted fleet of Antony maintained a brave resistance for some hours after his flight; but at length was completely overpowered and destroyed, three hundred ships being sunk or taken, and the whole strand covered with wrecks, and the bodies of the dead. For several days the army of Antony could not believe that he had deserted them; and remained in anxious expectation of his arrival, to renovate his fortunes on a more stable element. When at last assured of his flight, they entered into terms with the victor, who was now undisputed lord of both sea and land.

Death of Antony. B. C. 30.

After this fatal battle, Antony continued his flight to Egypt, a prey at once to shame and to ungovernable rage. For some time he refused to see Cleopatra, whom he accused of having caused his overthrow. But having exhausted his wrath, he returned to the embrace of the ensnaring syren, and again gave himself up to the excesses of voluptuous enjoyment. Meanwhile, the cautious Octavius was drawing his toils closer around his victim. The defences of Egypt were taken or surrendered; and in a short time Antony was reduced to such straits, that he could neither fight nor fly. Hemmed in, deserted by his own troops, suspicious of the Egyptians, distracted by jealousy and rage, he lost all self-control, bursting into fierce gusts of frantic passion, then sinking into the stupor of despair. Even Cleopatra became alarmed with these storms of the furious madman, and caused a report to be spread that she was dead. This report roused the Roman in the heart of Antony; and having nothing now on earth to love, and the path of ambition being closed, he threw himself on his own sword, but failed to inflict a wound immediately mortal. While struggling in the agonies of death, he was told that Cleopatra was still alive. Somewhat reviving at this intelligence, he caused himself to be carried into the presence of Cleopatra, where, calling for a draught of wine, and fixing his eyes on the fascinating woman, for whose sake he had lost the world, he expired.

B. C. 30.

Octavius was now left without a rival, sole master of the Roman world. On seeing the body of Antony he betrayed some emotion; but gave orders that the utmost attention should be paid to Cleopatra, and especially that she should be prevented from dying by her own hand, as he was anxious that she should adorn his triumph at Rome. She seems to have cherished the hope of gaining the same influence over him that she had enjoyed over Cæsar and Antony; but the cold and passionless temper of Octavius was proof against her blandishments. Disappointed in this expectation, and dreading the disgrace of being led in captivity to adorn the triumph of her conqueror, she eluded the vigilance of her Roman guards, and having imbibed poison, either from the bite of an asp, or from the point of an envenomed needle, death rescued her from that indignity.

Egypt was then reduced to the form of a Roman province; and its immense wealth was transported to Rome to replenish the exhausted treasury, and to pay the troops by whom the conquest was thus achieved. Soon after his return to Rome, Octavius received from the senate the appellation of Augustus, by which name he is henceforward to be known in history; and by an unanimous vote, they committed to him the entire government of the state. With this vote ended the Roman republic; and from this period was dated the commencement of the Roman empire, under its first undisputed sovereign, Augustus Imperator.

SECTION III.

Augustus Cæsar. B. C. 30.

Augustus Cæsar now found himself possessed of the undisputed sovereignty of Rome, every competitor having perished, and the servile senate being ready to bestow upon him all titles, honours, and privileges which he could desire. He had before him the contrasted fates of Sylla and of Cæsar; the former of whom died in peace after relinquishing the perpetual dictatorship, the latter was slain when in its full enjoyment. For a time, it is said, he hesitated whether to retire, like Sylla, into private life, or to retain imperial power; but by the sage advice of the politic Maecenas, his chief favourite, he was persuaded to retain it, and merely to govern under republican forms, though possessing a real and absolute monarchy. In consequence of the same advice, he laid aside the dictatorship, as too manifestly despotic, was annually chosen consul, and finally received the consular power in perpetuity; and by being created perpetual tribune, his person was rendered sacred and inviolable, which gave a conventional security, at least to his life, and led to the enactment of the *judicia majestatis*, or accusations of *high treason*. As imperator he retained the command of all the forces; and by assuming the censorship and the pontificate, he became possessed of the right of raising or depressing in rank, and of regulating every thing that depended upon religious ceremonies.

This supreme dominion, which his own power would have enabled him to seize and perpetuate, he pretended to be unwilling to retain, and made an offer in the senate of laying it down. This they requested him not to do; and upon their urgent entreaties, he consented to retain it for a period of ten years; on the expiration of which, the same form was repeated, and a similar prolongation conferred. This example, followed by succeeding emperors, gave rise to the *sacra decennalia*, festivals celebrated at every renewal of the imperial authority. It is not necessary to imagine that this decree of the senate was entirely the result of slavish submission to absolute power. Many of the senators could still remember the horrors of those contentions for supremacy which had taken place in the times of Marius and Sylla, and of the two triumvirates, and might be really apprehensive of equal convulsions and bloodshed, should he abdicate his power, and thus re-open the sources of contention, anarchy, and bloodshed. The wiser of them might see, that there did not now survive enough of republican virtue to render a republic any longer possible, and as Augustus, after the fall of all his antagonists, had displayed a great degree of mildness and clemency, they might fairly conclude, that his government was the best of which Rome was then capable, and might therefore desire its perpetuity, as the best method of securing the welfare of the empire. On his own part, his character had begun to assume an aspect very different from what it bore at the beginning of his ambitious career. At that time, its chief element appeared to be cold, remorseless cruelty; now it became mild, placable, benignant, alike respectful to the senate, and benevolent to the people. The truest patriot might therefore be most earnest in desiring the continuance of his power, however it might have been acquired.

But while Augustus received equal manifestations of attachment from the senate and the people, he was sufficiently aware, that to the army he owed his elevation, and that its favour must be secured. It could neither be disbanded nor retained in one place and body, with due regard to safety. Following the example of Sylla, he dispersed his veterans over Italy, settling them in thirty-two colonies, to make room for which, the former proprietors were in many instances dispossessed of their property. The settlement of one of these colonies near Mantua, was the cause of Virgil's removal to Rome. Eight entire legions were posted on the Rhine, four on the Danube, three in Spain, and one in Dalmatia. Eight more were stationed in Asia and Africa. The whole standing army of the empire amounted to upwards of one hundred and seventy thousand men. There were also quartered in Rome and its vicinity twelve cohorts, amounting to about ten thousand men; nine of these, called the prætorian bands, were intended as the imperial body-guard, the rest for the garrison of the city. These prætorian cohorts afterwards became not the guards merely, but also the dispensers of imperial power. Two powerful fleets were also maintained, the one in the Adriatic sea, the other for the protection of the western Mediterranean. As Augustus still allowed the senate a nominal share in the government, the appointment of lieutenants for the administration of affairs in some of the provinces was left to them, the others he himself retained; but as the imperial provinces were those on the frontiers of the empire, where the troops were stationed, the armies constituting the real power were still under his command. The financial affairs of Rome he also arranged anew, taking care to cause the treasures of the empire to flow chiefly into his own private and military coffers. At this period, the state revenue of Rome is computed to have amounted to upwards of forty millions of our money. These revenues were drawn chiefly from tithes charged on conquered lands, tribute and customs from provinces, crown lands, taxations amounting to a twentieth upon inheritances, and fines of different kinds imposed by different laws. Of these the tributes and customs from the provinces, and the rental of the crown lands, were by far the most productive, directing the main stream of wealth into the imperial treasury.

The internal administration of affairs being thus arranged, Augustus had leisure to attend to its enlargement, by conquests on the frontier. Nor were these inconsiderable. Western Gaul, and the mountainous districts in the north of Spain, were completely subdued. An expedition into Armenia, if of little consequence in itself, was nevertheless very gratifying to Roman pride, by being the means of recovering from the Parthians the standards that had been lost in the unfortunate campaign of Crassus. In Africa, the boundaries of the empire were extended into very remote regions, productive however of little else but empty fame. But the most important of these conquests was that of the regions south of the Danube, Rhætia, the country of the Vindelici, and Noricum, as well as Pannonia, and afterwards Mœsia. The arms of Augustus could not, however, penetrate far into Germany, defended as it was both by the determined valour of its inhabitants, and by its extensive forests and marshes. The chief successes in Germany were obtained by the valour and skill of Tiberius and Drusus Nero, especially the latter, sons of the empress Livia by her former husband. A peace being at length concluded with the Germans, and Augustus not being desirous of extending his dominions beyond the territories over which he had obtained complete possession, and which were comprised within well-defined boundaries, the world obtained repose, and with great rejoicing, the temple of Janus was formally closed, to intimate the existence of universal peace.

During this period of general tranquillity, when the world was at rest, and a deep calm was brooding over the nations, in this "fulness of the times," there was born at Bethlehem in Judæa, of the lineage of David, the *Prince of Peace*, the *Saviour of the World*, whose coming thus brought with it both a foretaste and earnest of what it was destined to secure, "on earth peace, and good-will towards men."

.D. 9.

But this universal calm was of brief duration. The Roman forces in Germany had been entrusted to the command of Quintilius Varus, who exercised his power in a harsh and oppressive manner. This the high-spirited Germans could not brook, and a revolt was planned and executed under the management of Arminius (Herman), who succeeded in drawing the Roman army into a position in which they could neither fight nor fly. Varus himself, with three legions and six cohorts, perished on the field, or in an ineffectual attempt to secure a retreat. The destruction of this army preyed deeply on the spirits of Augustus, who nevertheless exerted himself to remedy the disaster, by sending first Tiberius, and then Germanicus, the son of Drusus, into Germany, at the head of a more numerous force. These German wars were continued with more or less vigour throughout the remainder of the reign of Augustus, and with more or less success, generally under the brave and skilful command of Germanicus, who acquired for himself a very brilliant renown, and the esteem of the whole empire.

In addition to these public troubles, Augustus suffered great affliction from the misconduct and the calamities of his family. Not having a son to succeed him in the empire, his wife Livia engaged in the most restless intrigues to secure the succession to her own children by her former husband. Augustus, on the other hand, destined the empire to Marcellus, his nephew and son-in-law, to whom he had given in marriage his only daughter Julia. Upon the early death of Marcellus, a youth of high promise in every respect, Augustus manifested his intention of leaving the empire to his grandsons, the sons of Julia by Agrippa, to whom she had been married after the death of Marcellus. He gave them the title of "princes of the youth;" and this undisguised favour so much offended Tiberius, that he withdrew from the court. The premature death of the two young princes, not without suspicion of having been poisoned by the empress Livia, to make way for her own son, caused the recall of Tiberius. Augustus bestowed upon him his daughter Julia, the widow of Marcellus and Agrippa, requiring him at the same time to adopt Drusus Germanicus, the son of his brother Drusus. The infamously licentious conduct of Julia at length so much disgusted her father, that he banished her to the island of Pandataria. Thus harassed by domestic troubles, the master of the world found that imperial power could not secure happiness, or lessen one of the pangs that waste the weary heart. He was seized with a dangerous illness while at Naples, and becoming worse while on his return, was unable to reach Rome, but expired at Nola, in the seventy-sixth year of his age, after having swayed the sceptre of imperial power during forty-four years.

D. 14.

berius.

The vacant throne was now ascended by Tiberius Claudius Nero, son of Livia, and latterly adopted son of Augustus. Almost the first act of Tiberius was to secure the empire by causing the murder of Agrippa Posthumus, the third son of Agrippa by Julia, thus completing the bloody policy by which his mother had opened his way to the sovereignty. He was in his fifty-sixth year when he succeeded to the empire; and though he had given evidence of the possession of by no means contemptible talents in his younger days, especially in his German wars, he had so long practised the arts of dissimulation and guile, that all his better mind seemed to have perished, and his baser qualities alone remained, or rather to have been stimulated into unnatural strength. Though now possessed of absolute power, he still continued to practise the subtle wiles of a dark and crooked policy, and to seek to accomplish by deceit what he could easily have done by strength. The murder of young Agrippa removed the most formidable rival; but the high renown of his nephew Germanicus, then waging successful war in the country whence he acquired his name, excited at once his envy, his hatred, and his fear; and he recalled him, on pretence of giving him the honours of a triumph. The residence of Germanicus at Rome could not long be endured by Tiberius; he was therefore sent into Syria, to quell the disorders of the east. Along with him were sent Piso and his wife, whose secret directions may be conjectured from their actual conduct, which was to harass him by every means in their power; and when he died, there were not wanting pregnant causes of suspicion that his death had been hastened by poison. The death of Germanicus was deplored by the whole Roman people, as a great public calamity, which none seemed more to deplore than Tiberius, while he inwardly rejoiced in the success of his atrocious villany.

Death of Germanicus.

In public life Tiberius was equally deceitful and cruel as he had been in private, and to his own relatives. Towards the senate he professed great respect, at the very time when he was depriving them of even the slender power which Augustus had left. Any remains of public virtue, which the senate had hitherto possessed, died rapidly away; and ceasing to exercise an independent authority in a free state, it became the passive instrument of the most brutal tyranny. Every deceitful person is necessarily at the same time suspicious. Full of guile himself, the dark-hearted emperor suspected every other man to be equally guileful. Hence his encouragement of innumerable spies and informers, who were ready fabricators of accusations, when they could detect no real criminality. The constant terrors of the suspicious tyrant increased his natural cruelty, till he ripened into a perfect monster of barbarity, delighting to glut his eyes with the agonies of his tortured victims.

But the most suspicious of tyrants must trust some person, were it but to have an instrument to execute their crimes; and as none but abandoned persons can be their instruments, they never trust without being betrayed. Tiberius reposed his chief confidence on Sejanus, præfect of the prætorian guard, a man whose crimes, if possible, surpassed those of the emperor himself. For eight successive years did Sejanus retain an undivided influence over the mind of Tiberius; and during that period he contrived to procure the death or banishment of almost every person who might have checked his progress to the possession of imperial power, which was the object of his treacherous ambition. The death of Drusus, the emperor's son, is attributed to Sejanus, as also the death of the two eldest sons of Germanicus, and the banishment of their mother Agrippina. The youngest son probably escaped in consequence of his almost constant residence with the army. But the master-stroke of policy by which Sejanus strove to secure his object, was his persuading the emperor to remove from the cares and dangers of Rome, and to indulge his passions in a retirement where he would have none around him but his depraved ministers of vice. Tiberius retired to Capreæ, where he abandoned himself to the perpetration of the most disgusting and unnatural vices, leaving Sejanus at Rome, in the possession of all but the name of imperial power. To this base and bloody favourite the senate displayed the utmost servility; the people gave him honours second only to those of the emperor; and the sceptre itself seemed on the point of passing into his grasp, when he was accused to Tiberius of plotting his death. The imperial dissembler conferred the consulship on Sejanus; and by the messenger who conveyed this honour, sent a letter to the senate, accusing him of treason. When Sejanus came to the senate to receive his official dignity, he met his accusation, was instantly condemned, dragged through the streets, and put to death with the utmost ignominy by those who a few hours before followed him with acclamations.

Sejanus.

Fall of Sejanus.

The fall of Sejanus seemed only to increase the suspicions and the barbarous cruelty of the debauched and monstrous tyrant. He felt he had no friend; he knew he could not be loved; he was content to be hated, provided he were feared. At length, feeling the approach of death, he named as his successor Caius Caligula, the only surviving son of his murdered nephew Germanicus. Still, though consciously dying, the consummate dissembler strove to deceive not only his courtiers, but even his physicians. Pretending to feel a restoration of health and strength, he made a sumptuous feast, and continued at table, as if in the height of enjoyment, till he was seized with a fainting fit which threatened to be mortal. His courtiers forsook him in haste to flock to Caligula; but Tiberius reviving, they became alarmed lest he should recover, and Macro, the captain of the guard, smothered the helpless wretch, whose fate was thus hastened by the recoil of his own deceit and cruelty.

A.D 37.

Caligula.

Caius Cæsar Caligula (so surnamed from the common military buskins, *caligæ*, which he was accustomed to wear), was joyously welcomed to the throne by both the senate and the people, on account of the deep love and regard still cherished for the memory of his father Germanicus. His first acts served to confirm the hopes which had been entertained of him. He liberated all the state prisoners, and drove from the court and senate all the spies and informers whom Tiberius had employed. His voyage to the islands of Pandataria and Pontia in the midst of tempestuous weather, to remove the ashes of his mother and brothers, seemed also an amiable proof of a sincere filial and fraternal piety. He restored some of the most equitable of the decrees of Augustus, which Tiberius had repealed, and gave other proofs of his intention to act in all respects for the promotion of the public welfare. But these hopeful symptoms were doomed to suffer an early and a fatal blight. He had been only about eight months on the throne when he was seized with a severe and dangerous illness, from which he recovered, so far as bodily health was concerned; but his mental sanity appears to have sustained an irremediable shock.

From that time forward, animal passions of the fiercest kind domineered over him uncontrolled, or, if not animal passions merely, with no more of intellect than was enough to render them fearfully malevolent. To enumerate his crimes would be too hideously revolting, so utterly and excessively unnatural were the murders, the incests, and the brutalities in which this insane, or demon-possessed monster revelled. Murder was his daily amusement; and he took a fiendish delight in witnessing the dying pangs of his victims, whose sufferings he strove to protract, that they might, as he said, "feel themselves dying." He assumed divine honours, erected a temple to himself, and instituted a college of priests, to superintend the worship of the new god. He likewise deified one of his sisters; and on her death, it was equally dangerous to rejoice in her divinity, and to mourn for her death. It was customary for him to invite his favourite horse to sup with him; and he was only prevented by death from raising the animal to the dignity of consul. His prodigality was equally extravagant with his other crimes. In one year he expended the almost boundless wealth which had been accumulated by Tiberius, in shows of the most lavish and wasteful kind. One of these was a vast bridge of vessels at Puteoli, across an arm of the sea, three miles and a half broad, and so formed as to resemble a street at Rome. A feverish dream of military glory next seized his distempered brain; and he made great preparations for an expedition against the Germans. Like all his undertakings, it ended in consummate folly. Instead of conquering Germany, he led his army to the sea-shore at Boulogne in France, drew out his troops in order of battle, then causing them to fill their helmets with shells, which he termed the spoils of the ocean, he returned to Rome, and demanded from the senate the honours of a triumph for his warlike exploits.

Rome at length grew sick of enduring the frantic guilt and reckless tyranny of Caligula. A conspiracy was formed against him, and he was assassinated by Cassius Chærea and Cornelius Sabinus, two officers of the prætorian guards. His body was allowed to lie for some time exposed to public contumely, but was finally thrown into a grave, without any marks of honour or respect. His wife and infant child were also slain by the conspirators, who thought thus to secure themselves against the danger of future punishment.

A.D. 41.

Upon the death of Caligula, the senate began to cherish hopes of altogether abolishing the imperial power, and restoring, if not a republican, at least an aristocratic form of government. But the populace had too long enjoyed the donations of grain, and the amusements of the amphitheatre, supplied to them by dictators and emperors, to be disposed to favour a restoration of power to the senate. And the prætorian cohorts, stationed on the Quirinal hill, were too well aware that the continuation of their power depended upon the continuation of a monarchy, to be willing to tolerate any such revolution. Numbers of the conspirators, or those who were suspected to be such, were slain by the excited populace and the soldiers; and when the soldiers accidentally discovered Tiberius Claudius, brother of Germanicus, and uncle of the late emperor, they dragged him from his hiding place, and resolved to raise him to the vacant throne. The senate found it impossible to resist; and thus a person who had hitherto passed his life in unregarded obscurity, despised on account of his mental imbecility, was placed at the head of the empire. Thus raised to the throne by the power of the prætorian guards, Claudius set the pernicious custom of rewarding their deed by granting them a donative. This weak man was governed, as usually happens, by worthless favourites, and abandoned women. The infamous conduct of the empress Messalina has rendered her name proverbial; and her cruelty and rapacity were as unbounded as her licentiousness. At her instigation, it was but too common for the emperor to put to death some of the most wealthy of the nobles, and to confiscate their estates, with the money arising from which she pampered her numerous paramours. To such a pitch of unblushing effrontery did this abandoned woman proceed, that she at length openly married Silius, a noble youth, one of the partners of her crimes, purposing to complete her guilt by the murder of the emperor; but Claudius having received private information, gave orders for her death, and she was slain in the gardens which she had so long polluted by her unequalled criminality.

Claudius.

Death of Messalina

War in Britain.

Messalina had accompanied Claudius in an expedition to Britain, and given birth to a son named Britannicus, whom he exhibited to the army as his destined successor in the empire. This expedition was occasioned by the previous success of one led by the prætor Aulus Plautius, and by Vespasian, who, after a succession of severe battles, subdued all the country south of the Thames. After the emperor's return to Rome, Ostorius Scapula continued to conduct the war in Britain with great vigour and success, extended the province to the banks of the Severn, and finally succeeded in taking prisoner the celebrated Caractacus, or Caradoc, who had so long withstood the power of Rome. The native grandeur of soul displayed by this comparatively rude hero, excited in the mind of Claudius so much admiration, that he ordered his fetters to be struck off, and treated him with the most marked distinction.

Caractacu

The fall of Messalina was brought about in a great measure through the intervention of Narcissus, the emperor's freedman, who, along with Pallas, another manumitted slave, engrossed the chief favour of the weak-minded sovereign of Rome. The power wielded by this race of men, was a new feature in the degeneracy of the imperial court, but one which thenceforward was but too common, and as baneful as it was disgraceful. In men of this denomination, there was almost of necessity the most complete blending of abject sycophancy to the emperor, with despotic tyranny and insolence to all his subjects.

grippina.

D. 54.

Not long after the death of Messalina, Claudius married his own niece, Agrippina, daughter of Germanicus, a woman of strong natural abilities, but of insatiable avarice, extreme ambition, and remorseless cruelty. Her influence over the feeble emperor was boundless, and was displayed in the most glaringly ostentatious manner. She prevailed on him at last to set aside his own son Britannicus, and to adopt her son, Domitius Ahenobarbus, by her former husband, giving him the name by which he is best known, Nero, and constituting him heir to the imperial throne. To secure the succession in this channel, she gained over Burrhus, præfect of the prætorian bands, to whom she entrusted the charge of the youthful aspirant, thus giving him a reason to maintain his fidelity to one over whom he was sure to obtain influence. But Claudius having shewn some disposition to change the succession, and to restore it to Britannicus, Agrippina caused him to be poisoned by one of his own slavish favourites. His death was concealed by the empress till she had completed all her machinations for securing the throne to her son, who was then produced to receive the congratulations of his subjects.

ero.

th of ippina.

Nero Claudius Cæsar, through the devices of his mother, and by the support of the prætorian guard, ascended the vacant throne at the early age of seventeen. During the first four or five years of his reign, he acted generally under the advice of his tutor, Seneca the philosopher, and Burrhus, præfect of the prætorian guard, and for that period he maintained a comparatively favourable character. The turbulent and ambitious conduct of his mother gave him great annoyance; and the opposition which she experienced from Seneca and Burrhus, together with the mortification of perceiving the rapid decline of her influence over her son, served only to stimulate her to more dangerous and wicked conduct. She threatened to excite a revolution in behalf of Britannicus, son of the late emperor; and this was the signal for the murder of the unfortunate youth, by the orders of Nero. The depravity of Nero was now beginning to shew itself. Poppæa Sabina, a woman of infamous character but of great beauty, had acquired greater influence over him than was possessed by either his mother or his sage counsellors, Seneca and Burrhus. A hideous rivalry began between this aspiring woman and Agrippina. To secure her influence, Poppæa instigated Nero to the murder of his mother; and to recover her power, Agrippina began to amass wealth, bribe the troops, and prepare measures for a conspiracy against the life of her own son. At length Poppæa prevailed, and Nero gave orders that his mother should be put to death, which was perpetrated while she lay asleep. After her murder, the monster himself gazed on the dead body, and expressed his admiration of her beauty.

He soon afterwards divorced his wife Octavia, daughter of Claudius, and married the infamous Poppæa. The death of Burrhus, which happened about the same time, gave him an opportunity of raising to the command of the prætorian guards a man whose disposition was more congenial to his own, Tigellinus, the corrupt and bloody tool of a depraved, licentious, and cruel tyrant. In his early youth Nero had paid some attention to the study of music, and even of poetry; and his excessive vanity led him to be covetous of public applause as a musician. He first exhibited publicly on the stage at Naples; and being extremely gratified with the vehement applause that followed his performance, he frequently afterwards appeared in the theatres, and played on his lute, in the guise of a common musician. In a tour through Greece he received such unbounded applause, conveyed in such flattering terms by the polished natives, that he declared none but Greeks were worthy to hear him play and sing. Yet from these skilful flatterers he exacted the most oppressive contributions, for the supply of his lavish prodigalities.

War in Britain.

Boadicea.

During his reign the war in Britain was renewed, under the command of the brave and skilful Suetonius Paulinus. This politic commander, perceiving the influence which the Druids exercised over their countrymen, determined to put to death the whole druidical order, and to extirpate their religion. For this purpose he seized upon and devastated the isle of Mona, or Anglescy, their chief seat, cut down the sacred groves, and burned numbers of the Druids on their own blood-stained altars, and with their own homicidal fires. While he was thus engaged, a general insurrection of the conquered province broke out in consequence of the barbarous outrages inflicted on Boadicea, queen of the Iceni. Instigated by her wrongs, the natives everywhere flew to arms, destroyed several Roman stations, and among others the considerable colony of Verulamium (St. Alban's). Not less than 70,000 persons are said to have fallen victims to their vengeance. Suetonius hastened back to the support of his countrymen, and defeated the insurgent Britons with terrible slaughter. He was soon afterwards recalled by Nero, and the war in Britain was for a time suffered to languish.

Burning of Rome. A. D. 64

Persecution of the Christians.

In the tenth or eleventh year of Nero's reign, Rome was visited by a vast and dreadful conflagration, which continued for six successive days, and laid waste the greater part of the city. Nero himself gazed on the progress of the devouring element with a strange and wild delight, reciting aloud in a theatrical manner some verses descriptive of the destruction of Troy. Great numbers of the people, and immense treasures perished in this conflagration, which, partly from his conduct at the time, and partly from some expressions which fell from him a short time before, Nero himself was suspected of having caused. To remove the odium of this dreadful suspicion, Nero not only began to rebuild the city in greater splendour than before, maintaining meanwhile the homeless inhabitants at his own expense, but also caused the Christians, who were now become numerous, to be accused of having set the city on fire. This false accusation caused the first persecution of the Christians, in which great numbers were put to death with tortures of unprecedented cruelty. The details of this bloody persecution come, however, more properly within the province of the ecclesiastical historian. Availing himself of the space left unoccupied by the devastations of the flames, Nero indulged his extravagant disposition in the erection of his celebrated golden palace, of which the dimensions were prodigious, and the materials so costly as to drain the wealth of an empire. To replenish his treasury, he exacted the most oppressive tribute from the provinces, and thus excited a spirit of strong disaffection, which at no distant period threatened almost the dissolution of the empire.

Death of Seneca and Lucan.

In the mean time a conspiracy at Rome, headed by Piso, was detected before it was ripe for execution. This gave occasion to Nero to display the worst qualities of his ferocious mind. Not only all who were really implicated in the conspiracy were put to death without mercy, and their effects confiscated to the use of the emperor, but great numbers were doomed to similar destruction for no other apparent cause than because they were wealthy, or in some manner had incurred the dislike of the tyrant. In this wholesale butchery perished the philosopher Seneca, and the poet Lucan, with many others of the best and noblest men of Rome.

Notwithstanding these horrible barbarities, Nero was almost a favourite with the corrupt and mercenary populace. A very large proportion of the inhabitants of Rome had been accustomed, even from the turbulent days of the Gracchi, to be supported almost solely by the donations and distributions of corn, bestowed upon them by designing demagogues. Marius set the example of composing armies out of this degenerate city rabble; and even when this example was not followed, it was still found necessary to continue the distributions of corn, together with the public shows of gladiators and wild beasts in the amphitheatre. To these Nero had added supplies of wine and animal food *(congiaria et viscerationes)*; so that the populace was both amused and fed at the public expense, while the weight of the tyranny was chiefly borne by the most distinguished class of citizens, the senate, and the nobility; and heaviest by the most illustrious. To such a state of affairs the degenerate populace had little to object; but men of rank and merit groaned beneath an oppression no longer to be endured.

The provinces, however, were the first to make an attempt to throw off the intolerable yoke. Julius Vindex raised the standard of revolt in western Gaul. The army in Spain proclaimed their general, Galba, emperor; and they were joined by the troops in Lusitania, commanded by Otho. The intelligence of these revolts filled Nero with consternation; from which he was somewhat relieved by the tidings of the defeat of Vindex by Virginius, who had maintained his allegiance. This joy was of short duration; for Nymphidius, colleague of Tigellinus in the command of the prætorian guards, found means to persuade these troops to declare for Galba. The ruin of the emperor was now inevitable. Bereft of friends, of courage, and of presence of mind, he fled in trepidation disguised from the city, found a temporary refuge in the house of his freedman, Phaon, and hearing the trampling of horsemen who had been sent in pursuit of him, stabbed himself in the throat with a dagger, and miserably ended his miserable life.

A. D. 68.

Galba.

Servius Sulpitius Galba was universally received as emperor after the death of Nero; although Nymphidius attempted to take advantage of his slow progress towards Rome from Spain, and to get himself raised to the throne by the prætorian guards. Virginius Rufus, who had defeated Vindex, voluntarily submitted to Galba, as did also the armies in other parts of the empire. Strengthened by this ready reception, Galba endeavoured to abridge the dangerous power of the prætorian guards. Habituated to the rigid discipline of the camp, he exerted himself to restore somewhat of the ancient and hardy virtues of the republic, discountenanced sloth, idleness, and luxury, and even exhibited a penurious meanness of temper, unbecoming his exalted station, giving colour to the accusations of avarice which were made against him. The legions stationed in upper Germany, who had been somewhat tardy in acknowledging his elevation to the throne, began to be more disaffected, and to threaten to raise their own general, Vitellius, to the possession of imperial power. With a view to strengthen his tenure of empire, Galba appointed Licinius Piso, a youth of high promise, to be his successor. To this Otho had aspired, and immediately plotted the death of Galba. He readily secured the favour of the prætorian guards, who equally feared and hated the rigid discipline of the emperor. A revolt speedily ensued; Galba prepared to defend his power; and a contest taking place in the forum, the aged emperor was thrown down and trampled to death, after a reign of only seven months.

A. D. 69.

Otho.

Scarcely had Otho seized upon the sceptre, when he found himself engaged in a contest with Vitellius, who had been proclaimed emperor by his soldiers. The new competitor for imperial sway was joined by Valens and Cæcina, and began his march towards Italy at the head of a powerful army. Otho marched to oppose him. The antagonists met at a little village called Bedriacum, near the banks of the Po, and a severe and bloody engagement took place. Victory was for some time doubtful; but the superior discipline of Vitellius's army prevailed, and Otho was defeated with great slaughter. Seeing his prospects desperate, Otho gave up the contest, thanked his troops for their fidelity, and put an end to his own life, after a brief reign of about three months.

A. D. 69

Vitellius.

Vitellius began his reign by endeavouring to conciliate the favour of the populace and the troops by large donations and expensive amusements. He then gave a loose rein to his own debasing appetites, of which the chief was absolute gluttony of the very grossest kind. It is almost incredible, though stated by historians, that in less than four months he expended on the mere luxuries of the table a sum equal to about seven millions sterling. This bloated and pampered ruler was soon regarded by all his subjects with contempt and disgust. The unrestrained licentiousness of the soldiery tended equally to make his reign hated and feared by all who were exposed to the insults and outrages in which they indulged. To supply the funds necessary for the maintenance of his excessive luxury, he resorted to the too prevalent custom of listening to the accusations of spies, and putting to death all such accused persons, that he might seize upon their property.

While thus wallowing in the indulgence of the most debasing appetites, Vitellius was startled by tidings of a very alarming nature. During the reign of Nero an insurrection had broken out in Judea, and Vespasian had been sent to take the command of the army in Syria. The Jews made a desperate resistance, disputing, with almost invincible hardihood and indomitable bravery, every inch of their sacred territory. But this resistance, while it detained Vespasian in that country at the head of a powerful army, served only to mature their own fate. He had sent his own son, Titus, to offer his allegiance to Galba; but before his arrival Galba was dead, and Otho and Vitellius were contending for the empire. Titus returned to his father for instructions; and though Vespasian appeared ready to acknowledge Vitellius, his own troops were eager to raise him to the sovereignty. Mucianus, governor of Syria, and all the tributary eastern monarchs, urged him to comply with the wishes of his army, and his reluctance, real or feigned, yielded to their joint remonstrances. No sooner had he commenced his march towards Europe, than the Illyrian and Pannonian armies declared in his favour; and that of Illyricum, under the command of Antonius Primus, crossed the Alps and marched towards Rome to dethrone Vitellius. The Vitellian army, commanded by Cæcina, encountered that of Antonius near Cremona, but was defeated with great loss, and the city was taken. Antonius continued to advance on Rome, and crossed the passes of the Appennines while the emperor was hastening to secure them. Vitellius fled to Rome, which was soon invested by the victorious army of Antonius. An insurrectionary tumult arose in the city itself, during which the Capitol was burned to the ground, and Sabinus, the brother of Vespasian, was killed. The troops of Antonius at length forced an entrance into the city, stormed the quarters of the prætorian guards, and put those turbulent bands to the sword. Vitellius endeavoured to conceal himself, but was discovered, dragged through the streets to the place of punishment for common malefactors, put to death in the most ignominious manner, and his mangled carcass cast into the Tiber amidst the execrations of the multitude. Eight months and five days had this despicable wretch seemed to sway the sceptre of supreme dominion, when thus overtaken by the due reward of his debauchery and crimes.

A. D. 69

Vespasia

Flavius Vespasian obtained possession of the throne in his fifty-ninth year, and became the founder of a dynasty which gave three emperors to Rome. He was a man of rare and excellent virtues, thoroughly matured by a life spent in the exercise of public duties, and with no object superior to that of promoting the public welfare. Being well aware of the glaring abuses which had long been perpetrated with impunity in all branches of the administration, he set himself vigorously to the dangerous task of effecting a thorough reform. He restored the privileges of the senate, and gave it once more an actual power in the government. The courts of law were also subjected to a most salutary reform, and rendered again, what they had long ceased to be, courts of justice. The insubordination of the army, which had been the main cause of so many bloody revolutions, he repressed with a firm and steady hand; and restored in a great measure the discipline which had made it so powerful in its better days. He directed his attention also to the treasury, which had been quite exhausted by the corrupt and prodigal expenditure of his predecessors; and in order to replenish its coffers, he regulated anew the tribute and custom-dues of the provinces, and imposed a number of taxes; by which means, though he was accused of avarice, he placed once more the revenues of the empire on a stable basis, and restored them to a flourishing condition. The large sums thus raised Vespasian did not expend in revelry, neither did he hoard up in useless masses. He rebuilt the temple of Jupiter Capitolinus, which had been destroyed during the tumults that accompanied the fall of Vitellius; and adorned the city with many other public buildings of great elegance and splendour, thus evincing, that though rigorous and exact in his methods of amassing treasure, he knew, on proper occasions, how to use it with no parsimonious hand. Under him the empire began to breathe with fresh life, and to exhibit signs of prosperity and happiness, such as it had not known since the reign of Augustus. His son Titus being raised to the dignity of Cæsar, by which name the successor to the throne was designated, the peace and welfare of the empire seemed secured on a stable basis.

Destruc- ion of erusalem.

A.D. 70.

During the reign of Vespasian the arms of Rome were prosperous in various parts of the world. Several states bordering on the Roman dominions were reduced by his generals to the condition of provinces. But the most celebrated, though not the most formidable war which distinguished his reign, was that in which he was engaged when he was called to the throne, the war against the Jews. This was conducted by his son Titus, after his departure to Rome to enter on the possession of imperial power. The events of this memorable war are so well known that they need not here be detailed. Suffice it to state, that after Jerusalem had been closely invested, the Jews refused all terms of capitulation, blindly trusted in some terrible interposition of divine power to save them and consume their enemies, butchered each other with inconceivable barbarity during every temporary cessation of warfare, endured the wildest extremes of famine, and after suffering every form and kind of misery, to a degree unparalleled in the world's history, their city was taken, and together with their celebrated temple, was reduced to heaps of shapeless ruins; and such of them as survived these awful calamities were scattered over the face of the earth, and rendered a mockery, a proverb, and a reproach among nations. In consequence of this victory over the Jews, Titus and the emperor enjoyed together the honours of a splendid triumph, while the rich vessels of the temple of Jerusalem were in gorgeous procession borne in the train of the conquerors.

ar in ritain.

gricola.

Soon after this triumph the Batavian war broke out, caused by the civil wars for the empire, and threatening Rome with the loss of a province. It was at length brought to a propitious conclusion by Cerealis, after several sharp encounters, and by a treaty rather than a conquest. The Roman arms were more successful in Britain, during the reign of Vespasian and his immediate successors, than they had previously been. In his younger days, the emperor had himself been engaged in British wars; and being desirous of reducing the island completely under the Roman yoke, he gave the command to Cneius Julius Agricola, a man of extraordinary merit, a general and a statesman worthy of the best days of Rome. Not only the southern division of the island was subdued by this distinguished commander, but even the more remote regions of Caledonia, hitherto impervious to the Roman legions, were laid open. The gallant resistance of the brave Caledonians, under their leader Galgacus, was ineffectual; their untaught valour could not withstand the steady discipline of the Roman army, and they sustained a severe overthrow at the base of the Grampians. The Roman fleet coasting along the shore, ascertained the insular character of Britain; but so formidable were the mountain fastnesses of Caledonia, that Agricola did not attempt to penetrate farther into the country, contenting himself with constructing a chain of forts between the Friths of Clyde and Forth, to defend the southern districts, and to restrain the recoil and assaults of the unconquered Caledonians.

A.D. 79.

Thus glorious abroad, and beloved at home, Vespasian's life began to draw near its termination. Feeling the effects of age and weakness, he retired to Campania, to enjoy the benefits of a purer air than that of Rome, together with some relaxation from the cares of state. There he was seized with a malady which his own sensations told him would speedily prove mortal. His anticipations proved true; and he expired in the arms of his attendants, in the seventieth year of his age, and the tenth of his reign. It is worthy of remark, that Vespasian was the second of the Roman emperors that died a natural death, and the first that was succeeded by his son.

Titus.

Titus Flavius Vespasian, the conqueror of Jerusalem, ascended in peace the peaceful throne of his father. The very first acts of his reign gave promise of a period of unexampled felicity. Previously to that time he had indulged slightly in pleasures of a somewhat licentious character. From that hour he discarded all the ministers of his looser days, and being resolved to reform the state of public morals, began by reforming himself. Although strongly attached to the beautiful Berenice, daughter of Agrippa, the last king of Judea, he relinquished her society entirely, because he knew that such a connexion was disagreeable to the Roman senate and people. He abolished also the law of treason, under the sanction of which so many acts of tyranny had been committed; and he not only discountenanced, but severely punished, all spies and informers. His whole time was devoted to the duties of his high station; his chief pleasure consisted in rendering services and kindnesses to his friends and to his people. His courtesy and benevolence would doubtless find ample scope; yet it is recorded of him, that one evening recalling to mind the events of the day, and not finding that he had done any thing during its course beneficial to mankind, he exclaimed in accents of regret, "My friends, I have lost a day!" This well-known exclamation, and the course of benevolent deeds by which it was accredited, procured for him the truly glorious title of *The delight of mankind.*

Great eruption of Vesuvius.

Death of Pliny.

Yet the reign of that gentle-hearted and benignant emperor was signalised by some remarkable public calamities. In its first year Campania was laid waste by the most dreadful eruption of Vesuvius ever recorded. It devastated the surrounding country for many miles, overwhelming several cities, of which Herculaneum and Pompeii were the chief. The remains of these cities, excavated in modern times, have supplied inestimable stores to the antiquarian, and thrown great light upon the habits and customs of the Romans in domestic life. Pliny, the celebrated naturalist and philosopher, lost his life in this eruption, being suffocated in consequence of allowing his curiosity to attract him too near the fearful and dangerous scene. This calamitous convulsion of nature was followed by a destructive conflagration at Rome, which raged for three days, and destroyed a great number of edifices, both public and private. Titus exerted

A.D. 81.

himself to the utmost to alleviate these visitations of suffering; and while so engaged, his sympathies were called forth afresh by a dreadful plague which carried away vast multitudes at Rome. These disastrous events deeply grieved the benignant heart of Titus, and he strove incessantly to lighten the weighty calamities which pressed so heavily upon the empire. In the midst of these exertions and anxieties, he was seized with fever, against the fatal effects of which neither the skill of physicians nor the strength of his constitution could avail. After a short reign of two years ten months and a few days, he died in the forty-second year of his age, leaving behind him the reputation of being, if not the happiest, at least the best of monarchs.

Domitian.

Flavius Domitian, the younger brother of Titus, now ascended the vacant throne without opposition. On his first accession to imperial power, he seemed desirous of emulating the conduct of his brother. He paid the strictest attention to justice, bestowing a large portion of his time in hearing causes that had been appealed, and shewing himself ready to reverse every inequitable sentence. Pretending great disregard for wealth, he refused to accept the property bequeathed to him, distributing it among the natural heirs. To prevent his chief officers of state from receiving bribes, he bestowed upon them large sums, that they might be raised above the reach of temptation. He was, at the same time, remarkably liberal in granting donations, and providing the most expensive shows and amusements to the people. He confirmed all the grants made by his predecessors to the soldiers, and increased their pay, thus securing their favour and support. All the public buildings which Titus had begun he caused to be finished, sparing no expenditure to have them completed in the most splendid manner.

Having by these popular displays and manifestations secured the favour of the army and the populace, Domitian began to throw aside the mask which he had for a short time uneasily worn. Vanity and timidity seemed to be the leading elements of his character. The first led him to be inordinately desirous of obtaining popular applause, or even private flattery, however gross; the second rendered him incapable of performing any noble exploit, constantly afraid of public danger or private conspiracies, and consequently cruel to excess, when his victims were completely in his power. For it is an obvious truth, that cowardice and cruelty are inseparably allied; and the opposite is equally true, that the bravest man is also the most merciful. The vanity of Domitian made him desirous of a military triumph; and in order to obtain it he made an expedition into Gaul, against the Catti, a warlike German tribe which had invaded the province. Without having even seen the enemy, he demanded a triumph; and the servile senate granted the request of their weak and inglorious sovereign.

Dacian war.

A. D. 90.

The intelligence of the really glorious exploits of Agricola in Britain, excited the envy of Domitian; and he recalled that celebrated general, under a pretence of appointing him to the government of Syria. Agricola was too prudent to require a triumph, and retired into private life, which, however, he did not long enjoy, his death being hastened, as some suspect, by the guile of the emperor. He was soon afterwards involved in a more formidable war, in consequence of an irruption of the Daci and Getæ, who, under the command of their brave king Decebalus, crossed the Roman frontiers, and defeated the armies sent to oppose them. Domitian had now an opportunity of acquiring the renown of a warrior, but he wanted a warrior's heart. He did indeed march against the invader in person, taking care to turn his course so as to encounter the less-dreaded Marcomanni, by whom he was nevertheless defeated. Not daring to come to an engagement with the Daci, he actually purchased a peace, agreeing to pay Decebalus an annual sum of money, provided he would withdraw from the Roman dominions. This war is memorable, as being the first in which the northern barbarians attacked the empire not only with impunity, but with success; the pernicious precedent being thus established of purchasing peace, not with steel, but gold, in direct contrast to the old Roman usage.

A.D. 95.

In proportion as Domitian became truly despicable, did he increase in the most absurd and preposterous vanity. He now deified himself, and commanded his own statue to be worshipped as a god, at the very time that his mind was agitated with constant dread of plots against his life. Surrounded with spies and informers, he became more and more cruel, reviving the law of treason, and putting into terrific force all its bloody provisions. An unsuccessful revolt of the army in Upper Germany gave an opportunity to the timid yet sanguinary tyrant to indulge his ferocity, by putting to death all whom he suspected of disaffection. About the same time, a persecution was commenced against the Christians, partly because they refused to worship the statue of the emperor, and partly because his ignorant and superstitious mind had formed some vague notion of their connexion with the Jews, coupled with the dread, not yet either extinct or understood, of the appearance of a person born in Judea, who was to obtain the empire of the world. In this persecution several persons of illustrious birth and station perished, among whom was Flavius Clemens, a relation of the emperor; which shews that Christianity was beginning to make progress among the higher ranks of society.

A.D. 96.

But the end of this weak, vain, and cruel tyrant drew near. In order to secure the support of the army, he had augmented the pay of the troops one-fourth; and in order to meet the increased expense, he increased the number of those judicial murders, by the law of treason, which caused the property of the victims to be confiscated and become his own. He was in the habit of inscribing on a roll the names of those persons whom he designed to put to death, and kept it carefully in his own possession, treating them, in the meanwhile, with the most flattering attention. This fatal roll was one day taken from under the cushion on which he was reclining asleep, by a child who was playing about the apartment, and who carried it to the empress. She was struck with astonishment and alarm at finding her own name on the dark record, together with the names of others apparently highest in his favour. To them she communicated the knowledge of their danger; and they immediately resolved to preserve their own lives by destroying that of Domitian. This was accordingly done, notwithstanding all the precautions which cowardice and cunning could suggest; and, with the connivance of the prætorian prefect, Domitian perished by the daggers of Stephanus and Parthenius, officers of his own household.

Nerva.

He was the last of the emperors commonly described as "the twelve Cæsars;" although, in reality, the Cæsarean family terminated with Nero, and even previously its continuation had been only in the female line. Marcus Cocceius Nerva was chosen by an unanimous vote of the senate, on the very day of Domitian's death, that they might anticipate any attempt of the prætorian guard to make an emperor. He was of foreign extraction, though a naturalized citizen and senator of Rome, and owed his elevation to the throne solely to his stainless reputation. He commenced his reign by punishing informers, redressing grievances, repealing iniquitous statutes, enacting good laws, and dispensing favours with boundless liberality. He had made a resolution that no senator should be put to death by his command; but this, together with proofs of equal unwillingness to inflict punishment, encouraged the turbulent to indulge in their evil practices. An insurrection broke out in the prætorian guard, and to appease it Nerva was obliged to yield up the murderers of Domitian to their vengeance. Feeling his inability to control these seditious troops, he resolved to adopt as his colleague and successor in the empire Marcus Ulpius Trajan, by whose firmness and decision they might be kept in awe. The effect proved the wisdom of Nerva's choice. So high was the character of Trajan, that no person could be named equally worthy of the empire; and even the seditious prætorian bands submitted without a murmur. This, as it was the best, was almost the last act of Nerva's short reign. He was soon after seized with a fever, of which he died, having reigned only one year four months and nine days.

A.D. 98.
Trajan.

The peaceful and virtuous reign of Nerva was the harbinger of happy days to the Roman empire. The selection of Trajan prevented any contests for imperial power at the death of Nerva; so that the new emperor entered without the necessity of bloodshed upon the discharge of his high functions. He was by birth a Spaniard, though of Italian extraction; and had been early inured to the discipline of the army under his father, a commander of considerable reputation. When he himself became a general, he continued to practise the simple habits of a soldier, excelling his troops not in personal indulgences, but in courage and virtue. On the throne he continued to exhibit the same excellencies, only enhanced by the acquisition of a wider scope for their full development. Being superior to fear, it was natural that he should also be above harbouring suspicion. He therefore abolished the law of treason, *(judicia majestatis,)* and prepared to restore as much of the free Roman constitution as was compatible with the existence of a monarchy. He restored the elective power to the *comitia*, complete liberty of speech to the senate, and to the magistrates their former authority; and yet he ruled the empire with unrivalled firmness, holding the reins of power with a strong and steady hand. Of him it has been said, not in the language of panegyric, but of simple sincerity, that he was equally great as a ruler, a general, and a man: and only such a man could with safety, as emperor, have used the remarkable words, when giving a sword to the prefect of the prætorian guards, "Take this sword, and use it, if I have merit, for me; if otherwise, against me."

cian
r.

Soon after the accession of Trajan, the Dacian monarch, Decebalus, sent to demand the tribute with which Domitian had purchased a disgraceful peace. This Trajan indignantly refused; and levying an army, marched against the Dacians, who had already resumed their predatory incursions. The hostile armies soon came to an engagement, for both were equally eager; and after a desperate struggle the Dacians were routed with dreadful carnage. But so great was the loss of the Romans, that for some time they were not able to follow up their victory. It was however decisive; and the Dacians were compelled not only to forego their demands, but even to become tributaries to Rome. But unaccustomed to servitude, and led by their gallant king Decebalus, they mustered fresh forces as soon as they had somewhat recovered from their overthrow, and prepared for another contest. The warlike emperor was equally ready for the shock of arms. Not satisfied with expelling the invaders, he now determined to carry the war into the country of the enemy. For this purpose he erected a stupendous bridge over the Danube, with a strong fortification at each end, defeated the Dacians in every battle, marched into the heart of their country, and made himself master of the capital. Decebalus, despairing of success, killed himself, and Dacia was reduced to a Roman province, and secured in subjection by several colonies and standing camps. On his return from the Dacian war, the emperor was honoured with a triumph which lasted for the unprecedented period of 120 days.

A .106.

P cu-
tio

The deepest stain which rests on the memory of Trajan is the sanction which he gave to the persecution of the Christians. This persecution raged chiefly in the Asiatic provinces, where Christianity was most prevalent; and when Pliny the younger, at that time proconsul of Bithynia, wrote to Trajan for instructions respecting a matter which was causing the death of so many men who could not be convicted of any public crimes, the emperor returned an ambiguous answer, the purport of which was, "that the Christians should not be sought for, nor indicted on anonymous information, but that on conviction they ought to be punished." Such an answer was contrary to every principle of justice; for if criminal, they ought to be sought for, if not criminal, they ought not to be punished. The persecution being somewhat discouraged, was gradually suffered to abate.

Parthian war.

Trajan's passion for military fame had been but excited, not satiated, by his Dacian conquests. He next directed his attention to the East, and resolved to wrest from the Parthians, the most dreaded foes of Rome, the empire of central Asia. The first scene of his glory was Armenia, which he speedily reduced to a Roman province. Hence he advanced into Mesopotamia, throwing across the rapid Tigris a bridge not less remarkable than that which spanned the Danube. The greater part of what had been the Assyrian empire was overrun by his conquering arms. Selucia yielded to his might; Ctesiphon, the capital of the Parthian kingdom, could not resist his prowess; all opposition appeared fruitless, and victory seemed the companion of his march. Following the course of the Tigris, he arrived at the head of the Persian gulf, where he fitted out a fleet, and sailed to the entrance of the Indian ocean. Having thus traced the steps of Alexander the Great, emulating his conquering career, and with almost equal celerity, he began to retrace his course, returned to Ctesiphon, and placed a new sovereign on the throne of Parthia.

Age had now somewhat tamed his ambitious spirit, and seriously diminished the vigour of his hardy but overworn frame. He began to make preparations for his return to Rome, which he intended to be celebrated in a manner that should far outshine the most glorious triumphs of any of his imperial predecessors. But this triumph he was not destined to see. He had only reached Cilicia when he was seized with an illness which proved fatal, after a few days of paralytic stupor. During this period of comparative insensibility, the empress Plotina, who had accompanied him, contrived to procure Trajan's signature to a will nominating as his successor in the empire P. Ælius Adrian, his cousin, who was at that time with the army.

A D. 117.

Adrian.

Adrian having been declared emperor by the soldiers, immediately communicated to the senate the intelligence of Trajan's death, and of his own accession, excusing his not having waited till their sentiments should be made known, by pleading the impatient impetuosity of his troops. The senate were but too happy that the army had made no worse choice, and gave their ready concurrence. Adrian not having either the ambition or the military talents of Trajan, was more desirous of securing peace than of extending the empire: he therefore abandoned all the conquests of his predecessor, broke down the bridge across the Tigris, and reduced the empire within the boundaries marked out by Augustus, with the exception of Dacia. On his return to Rome the senate offered him a triumph, which he declined on his own account; but as great preparations had already been made, the triumph was celebrated, the statue of Trajan occupying the most conspicuous position. The ashes of that imperial warrior were afterwards placed in a golden urn on the summit of a magnificent column, 140 feet high, erected in the Forum Trajani to commemorate his victories, and still known by the name of Trajan's pillar.

But though Adrian was of a pacific disposition, he well knew what was required for the protection of the empire. He therefore restored the discipline of the army, and kept it in complete subordination. He also effected a general and vigorous reform in the internal administration of affairs, and displayed great personal aptitude for the study of comprehensive politics. To him the jurisprudence of Rome was deeply indebted, for the systematic order to which he reduced it. Being aware that little reliance could be placed on the accounts received from the distant provinces, and stimulated by the curiosity of an active temperament, he resolved to visit every province in the empire. In his visit to Britain, he followed the same policy which he had shewn with regard to the East; and instead of attempting a further reduction of Caledonia, relinquished a portion of Agricola's conquests, and erected a new wall, as a boundary-line of defence, from the Solway Firth to the Tyne, near Newcastle. He traversed Gaul and Germany, and revisited Asia, where he allayed some commotions that had arisen during his absence. Africa was also honoured by his presence. He spent a winter at Athens, again traversed the eastern provinces and Egypt, and then gratified his learning and his taste by another temporary residence in Greece. He was passionately fond of literature and the fine arts, and possessed of no inconsiderable attainments; and by his patronage of the productions of genius, he called forth another Augustan age, though not of equal brilliancy.

Adrian's wall.

During his reign, the persecutions of the Christians were renewed with great barbarity; and the emperor scarcely seemed to think it worth his while to protect that most unoffending class of his subjects. To the Jews he shewed nothing but insulting cruelty. He gave orders that a Roman colony should be established at Jerusalem, and changed its name to Ælia Capitolina. These indignities led to a fierce insurrection of the Jews, headed by an impostor who pretended to be the Messiah, and assumed the name of Barcohab, (the son of a star). A furious and sanguinary war, of nearly three years duration, almost entirely destroyed the very name and nation of the Jews, and it was decreed a capital crime if any Jew should again come within Judea.

Jewish war.

After his return to Rome, he adopted Commodus Verus as his successor, and on his death, Titus Antoninus. He was soon afterwards seized with dropsy, and the sufferings he endured made him almost frantic. Neither the attention of his physicians, nor the company of philosophers and poets could sooth him. Death at length terminated his sufferings at Baiæ, in the sixty-third year of his age, and after a reign of twenty-one years.

A. D. 138.

Antoninus.

T. Aurelius Antoninus, the adopted son and successor of Adrian, next ascended the throne. The first care of his reign was to prevent the senate from dishonouring the name of Adrian, by whose somewhat peevish and cruel conduct during his last illness, they had been offended. Not only did he succeed in this attempt, but the amiable anxiety which he displayed to protect the memory of his predecessor, earned for him the honourable designation of *the pious;* hence the name Antoninus Pius, by which he is best known in history. It had been arranged by Adrian, not only that Antoninus should succeed him, but also that Antoninus should adopt both Marcus Aurelius as his immediate successor, and Cesonius Commodus Verus, the son of that Verus whom he had first adopted. This arrangement Antoninus Pius immediately ratified, by giving his daughter Faustina in marriage to Aurelius, while he tolerated the profligate conduct of Verus, solely out of regard to the memory of Adrian.

The reign of Antoninus Pius furnishes few materials for the historian, passing away like a placid dream in the midst of universal tranquillity. It was undoubtedly the most peaceful and happy period that ever Rome knew, whether as a republic or an empire. It seemed to realise the ideal speculations of those philosophical politicians who looked for good government or rational happiness then, and then only, when philosophers should be kings, or kings philosophers. It is no mean portion of his praise, that he put an end to the persecution of the Christians throughout the empire. Few and slight were the wars of this reign. Of these, perhaps the most memorable was that waged in Britain by Lollius Urbicus, who not only repressed the incursions of the Caledonians, but recovered the district between the wall of Adrian, and the line of forts erected by Agricola. By the directions of the emperor, the newly acquired territory was secured by a complete wall, consisting of ditch and rampart, along the line traced by Agricola, and since known as the wall of Antoninus, or Graham's dike.

Wall of Antoninu

But the character of Antoninus was a more powerful protection to the Roman dominions than armies and military ramparts: so highly were his virtues respected through the world, that contending princes referred their disagreements to his arbitration, rather than to the fierce decision of the sword. The administration of all public affairs was conducted with the same spirit as if under the eye of the emperor, because every instance of malversation was immediately checked by removal from office, every instance of fidelity and judgment rewarded by the perpetuation of official rank. While the financial department was managed with the utmost frugality, no expenditure was spared which was evidently beneficial to the welfare of the community, in the foundation or improvement of useful institutions, such as the erection of public schools, and the maintenance of teachers. A liberal and enlightened encouragement was also given to commerce, with the view of rendering Rome the mistress of arts, as well as of arms, the centre of an empire acquired by the sword, but consolidated by civilization.

A. D. 16

Thus peaceful, happy, and beloved, Antoninus Pius reigned for a period of about twenty-three years, and died of a fever at one of his villas, universally regretted, and leaving to his own family nothing but his private property, and the inestimable heritage of a name, against which not even calumny had dared to insinuate a charge.

Aurelius.

Marcus Aurelius, called also Antoninus from having been adopted by his predecessor, and the Philosopher, from his proficiency in learning and his attachment to the opinions of the Stoics, succeeded to the throne, with the cordial approbation of both senate and people. According to the arrangement of Adrian, Aurelius associated with himself in the empire Lucius Verus, a person of a very dissimilar character, to whom he gave his daughter in marriage. This dissimilarity however rendering any thing like rivalry impossible was perhaps the cause of the cordial harmony which subsisted between the colleagues during the course of their common reign. Verus took the command of the army which was sent against the Parthians, over whom, by the skill and valour of his generals, he obtained several considerable victories, and captured several towns, while he was himself revelling in debaucheries at Antioch. At the conclusion of this war, Verus returned to enjoy the honours of a triumph which he had no share in obtaining. Unfortunately, the eastern army brought with it to Rome the infliction of a pestilential disease which was then raging in Asia, and which soon spread its ravages throughout almost the whole of the Roman empire. A dreadful inundation of the Tiber about the same time laid a large part of the city under water, and swept away immense quantities of grain from the fields and the public storehouses. This was followed by a famine which consumed great numbers, in spite of the utmost exertions of the emperor.

While thus weakened by pestilence and famine, the empire was assailed by a most formidable confederacy of the Germanic nations. The Marcomanni, and other tribes of similar origin, began to press forward with great force upon the Dacian province. The two emperors left Rome to take the field in person against these dangerous antagonists. Verus died, however, soon after the beginning of the war, leaving Aurelius to take the sole command, and to exchange his philosophic studies for the din of arms. He proved himself not unequal to the task, although the war was protracted and chequered by various vicissitudes, victory not always inclining to the side of Rome. During this war there occurred an event which has engaged the pens of several controversial writers. The Roman army happening to be reduced to great straits, blocked up by the Quadi, and in want of water, were relieved, and their enemies entirely discomfitted by a sudden storm of rain, accompanied with thunder and lightning, which flashing fiercely in the faces of the barbarians, filled them with terror, and scattered them into headlong flight. This event was considered as miraculous, and it is said to have been immediately preceded by the prayers of the twelfth legion, which was composed of Christians, and which afterwards received the name of *the thundering legion.*

A peace, or rather a cessation of hostilities, followed the victory thus obtained, and the emperor having returned to Rome, triumphed along with his son Commodus. An insurrection which had broken out in Syria, probably hastened his return; but Aurelius was not required to march against the rebel Avidius Cassius, who was killed by his own soldiers. The emperor treated the insurgents with great clemency, and took the family of Cassius under his protection, forbidding the senate to doom to death any who were suspected of being implicated in the rebellion.

Notwithstanding the general mildness of the personal character and the administration of Marcus Aurelius Antoninus, his memory is greatly disgraced by the systematic persecution against the Christians which he encouraged. It was not now merely the consequence of tumultuary violence, arising out of the intolerance of the idolatrous pagans, but was deliberately resolved upon, for reasons of state; the philosophic emperor, although despising all religion in his stoic pride, yet strictly prohibiting all change from the religions and customs of former times. Among the most illustrious victims of imperial intolerance was Justin Martyr, celebrated for his writings in defence of Christianity.

igration nations.

The war against the German nations was soon renewed, and assumed the most formidable aspect. Not merely the tribes on the frontiers of the empire took up arms, but throughout the interior of all the northern nations there was a general commotion, a wide upheaving and unsettling of whole races, and a pressing forward of a living tide, which threatened to overwhelm every thing in its progress. This was in fact the first symptom of the great migration of nations, then beginning, and which ceased not till it completely subverted the Roman empire, filling it with a new population, whose descendants constitute the kingdoms of modern Europe.

D. 180

In order to stem, if possible, the progress of this barbarian innundation, Aurelius again left Rome, and marched to Germany. His first efforts were crowned with success; but before he could follow them up, he was seized with a dangerous illness, which terminated his life, in the fifty-ninth year of his age. With Aurelius, the glory and the happiness of the Roman empire may be said to have expired, and that not uncharacteristically, in the reign of an emperor who was distinguished by considerable acquirements in learning, taste, philosophy, and by external respect for all religions, but real regard for none.

mmo-
d.

The commencement of the reign of Commodus, son of the late emperor, was rendered disgraceful by a treaty which he formed with the Marcomanni, and which he obtained chiefly through the influence of money. Notwithstanding the care which M. A. Antoninus had bestowed upon his education, he was ignorant to an extreme degree, having neither abilities nor inclination for profiting by the imperial example and instruction. On his return to Rome he speedily shewed the bias of his natural disposition, giving himself up to the most unrestrained indulgence in the grossest vices. That he might do so without impediment, he entrusted all power to Perennis, præfect of the prætorian guard, a man of stern and cruel temper, who was at last slain by his soldiers for his severity. A conspiracy against the life of Commodus failed, and was followed by a long succession of judicial murders, to gratify the vengeance of the cowardly and vindictive tyrant. He was next threatened by a new danger of a very peculiar character. It had become customary for the licentious soldiery to desert in considerable numbers, especially in Gaul, and to roam about the country as bands of robbers and freebooters. A common soldier, named Maternus, put himself at the head of these banditti, and excited such terror, that he became an object of attention to considerable armies. Being surrounded, and in danger of ruin, Maternus formed the bold project of killing the emperor in the heart of his capital, and seizing the throne. Dispersing his adherents, they all hastened to Rome, individually or in small parties, and had nearly filled the city, when they were detected, and Maternus was put to death.

The cruelty and rapacity of Cleander, the freedman and new favourite of Commodus, excited a new insurrection, which nothing could allay, the prætorian cavalry being defeated in the streets by the populace, till the head of Cleander was, by the emperor's command, thrown to the insurgents. In the mean time, Commodus was indulging his base tastes and appetites, not only by gross sensuality, but by endeavouring to rival the gladiators in their savage occupation. Being a very skilful archer, and of great personal strength, he delighted in killing wild beasts in the amphitheatre, and thus pretending to rival Hercules. In the gladiatorial contests, he publicly engaged so often, that he was the conqueror in 735 combats. Within the palace itself, a conspiracy was at length formed by Marcia, one of the emperor's concubines, his chamberlain, and the præfect of the prætorian guards. Poison was administered by Marcia, in a cup of wine; and while under the influence of the deadly draught, he was assailed and strangled by a common wrestler, who had been prepared for that purpose.

A. D. 192.

Pertinax.

Immediately upon the death of Commodus being known to the senate, they elected Publius Helvius Pertinax to the vacant throne; a man of obscure birth, but of great personal merit, by which he had raised himself to a distinguished rank in the state, and in the estimation of all virtuous men. The undesired power thus offered to him, he reluctantly accepted; but prepared to use it for the general good of the empire. In order to accomplish this most desirable object, Pertinax was obliged to begin his reign by checking the lavish expenditure by which Commodus had sought to secure the support of the guards, and to introduce discipline and subordination into this turbulent band. This necessary reform was immediately followed by an insurrection, in which Pertinax was killed, after a brief reign of sixty-six days.

A. D. 193.

Didius Julianus purchases the empire.

During this scene of contest and blood, the citizens abstained as much as possible from all interference, though strongly attached to Pertinax; and after his death they remained quiet in their houses, waiting the new master whom the prætorian guards might nominate. These seditious troops having fortified their quarters, waited also to see what the senate would do; but finding themselves left in possession of imperial power, they issued a proclamation, offering the empire for sale to the highest bidder. Didius Julianus became the purchaser, and thus disgracefully acquired the throne. But the intelligence of these base and lawless transactions excited the indignation of the armies in the provinces, who considered themselves better entitled to appoint an emperor, than a factious band of only about ten thousand men. The army of Illyricum proclaimed their general, Septimius Severus; that of Syria, Pescennius Niger; and that of Britain, Clodius Albinus. A bloody civil war was the inevitable consequence of so many competitors for the sovereignty. In the mean time, the wretched Didius was still the nominal emperor. But the rapid advance of Severus towards Rome alarmed the senate, who passed a

Civil war

decree for his dethronement and death, which was almost instantly executed, thus depriving Didius of the enjoyment of his ill-purchased honours in the short space of two months. A.D. 193.

Severus. Severus began his reign by accomplishing what Pertinax was murdered for attempting. He disarmed and disbanded the prætorian guards, and banished them to a distance of one hundred miles from Rome, death being the penalty of a nearer approach. The murderers of Pertinax were executed without mercy, and some degree of order and subordination restored. But Severus, accustomed to military sway, knew no other method of maintaining his authority except by force of arms. Though he punished the late prætorian guards, he replaced them with a chosen body of his own troops greatly more numerous; not reflecting that the enjoyment of similar leisure, and the possession of similar favour, would soon render them equally licentious and turbulent.

Having thus seized the sceptre, it was necessary to defend it against those rivals who were eager to wrench it from his grasp. As he was most apprehensive of danger from Pescennius Niger, he wrote deceptive letters to Clodius Albinus, styling him Cæsar, and thus lulling him to inaction. He then marched against Niger, whom, after several contests, he finally defeated in a great battle near the Issus. Niger was soon afterwards slain; and Severus put to death, without remorse, all whom he suspected of being favourable to the cause of his competitor. He next attempted to compass the death of Albinus by assassination; but the plot being detected, Albinus prepared to defend himself by dethroning his enemy. Severus hastened towards Britain, and Albinus crossed from thence to Gaul. The two rivals met near Lyons; and a very bloody battle was fought between two disciplined and numerous Roman armies, which ended in Severus gaining a complete victory. When he saw that his hopes were destroyed, Albinus fell by his own hand; and Severus, after insulting the dead body of his antagonist, again displayed the innate ferocity of his heart, by murdering in cold blood all his friends and adherents. A second Parthian war demanded the presence of Severus in the East, where he was again victorious, and where his exploits almost rivalled those of Trajan.

The avarice and insolence of Plautianus, commander of the prætorian guard, produced great oppression and suffering, till he was killed by Caracalla, the son of Severus, in the very presence of the emperor. Severus next turned his attention to Britain, where the Romans had been losing ground, partly in consequence of Albinus having withdrawn a great portion of the army in his attempt to elevate himself to the throne. The emperor being at the head of a very powerful army speedily drove back the independent natives of Caledonia, and regained the country south of the wall of Antoninus, but lost so many troops in the successive battles which he was obliged to fight, that he did not think proper to push his conquests beyond that boundary. Feeling at length A.D. 211. his end approaching, he retired to Eboracum (York), where he appointed his two sons, Caracalla and Geta, to succeed him and reign conjointly, and soon afterwards expired, in the eighteenth year of his reign.

Caracalla and Geta. The two brothers, Caracalla and Geta, had scarcely begun their reign, when they also began their dissensions. After their return to Rome, the utter impossibility of any permanent reconciliation taking place between them, led to a proposal by mutual friends that they should divide the empire. To this neither would agree; and soon afterwards A.D. 212. Geta was murdered in the arms of his mother by the hand of the furious and savage Caracalla.

Having now obtained the undivided possession of a throne stained with the blood of his brother, he prosecuted his murderous course, exhibiting the tiger-like propensities of his savage nature, by destroying almost indiscriminately men and women, young and old, wealthy and humble. He lavished presents, treasures, and amusements among the soldiery with an unsparing hand, trusting by their means to maintain his power, and setting at defiance the hatred of senate and people. He traversed the provinces along the Danube, partly in a hostile, partly in a friendly manner; thence passed into Asia, where, by treachery, he obtained some advantages over the Parthians; thence to Egypt, where, being enraged against the Alexandrians, who had ridiculed his pretensions to be regarded as another Alexander, he almost depopulated the city by a dreadful massacre. Vengeance at length overtook the sanguinary tyrant; and A.D. 2 he was murdered by the orders of Macrinus commander of the prætorian guards.

Marcus Opelius Macrinus was next placed at the head Macrin of the empire, by the soldiers, who were not aware that he had been accessory to the death of Caracalla. The new emperor was soon engaged in a war against the Parthians, where he gained no laurels, being obliged to purchase peace on terms highly disadvantageous to Rome. Some attempts which he made to restrain the extreme licentiousness of the soldiery excited a spirit of disaffection, of which Maesa, maternal aunt of the late emperor, availed herself to procure the empire to her grandson, a youth of fourteen, said to be the son of Caracalla, and a priest in the temple of the Sun at Emesa in Syria. This youth, named Heliogabalus, was proclaimed emperor by the legionary forces, on account of their attachment to the memory of his reputed father, Caracalla. Macrinus was defeated in an attempt to crush this rebellion, A.D. 21 and fell while endeavouring to escape by flight. His son, Diadumenus, whom he had associated in the empire, shared his fate.

Heliogabalus, thus raised to the throne, repaired to Rome, Heliogab lus. and began a course of licentiousness unparalleled in the annals of depravity. He was, in short, the most infamous wretch that ever disgraced a throne; his very existence seemed a stain upon human nature. To form some check to his shameless conduct, his grandmother caused him to assume his cousin, Alexander Severus, as his partner in the empire; but the abandoned and brutal boy attempted to procure his assassination, an attempt which soon proved fatal to himself. The prætorian guards, disgusted with the effeminate, licentious, and cruel tyrant, mutinied, and discovering him in a loathsome hiding place, a cloaca, dragged him A.D. 22 through the streets, put him to death in the most ignominious manner, and threw his body into the river, loaded with weights, that it might not be found and buried.

The new emperor, Alexander Severus, was of a character Alexande Severus. diametrically opposite to that of his predecessor. Among the first acts of his sovereignty, he banished all the guilty and abandoned creatures of Heliogabalus, restored the authority of the senate, and chose his counsellors and ministers of state of the best members of that body, and revoked all the persecuting edicts that had been issued by his predecessor against the Christians. This just and merciful procedure is thought to have been adopted by the advice of his mother, Mammæa, who maintained an intercourse with some of the most distinguished Christians, among others the celebrated Origen, and who was perhaps herself a convert. She was unquestionably a woman of great virtue, wisdom, and amiability of character; and as Alexander paid the utmost deference to her opinions and wishes, to her may be ascribed much of what was meritorious in the conduct of this young and excellent monarch.

But however desirous of peace, that he might prosecute Revoluti in Persi his schemes of reform, Alexander was soon called to encounter the perils and toils of war. A revolution in the east, which began in the fourth year of his reign, was pro- A.D. 22 ductive of consequences deeply important to all Asia. Ardeshir Babegan, or Artaxerxes, who pretended to be descended from the imperial race of ancient Persia, raised a

Persian war.

rebellion against the Parthian monarchs, the Arsacidae. The Parthian dynasty was overturned, and the ancient Persian restored; and with its restoration was renewed its claims to the sovereignty of all Asia, which it had formerly possessed. This claim gave rise to a war against the Romans, and Alexander led his troops to the East to maintain their imperial sway over the disputed territories. In the army he displayed the high qualities of a warrior, and gained a great victory over the Persians, but was prevented from following up his success in consequence of a pestilence breaking out among his troops. The Persians, however, were willing to renounce hostilities for a time, and the emperor returned to Rome in triumph.

Scarcely had Alexander tasted repose from his Persian war, when he received intelligence that the Germans had crossed the Rhine, and were invading Gaul. He at once set out to oppose this new enemy, but he encountered another still more formidable. The armies in Gaul had sunk into a great relaxation of the rigid discipline necessary for even their own preservation. Alexander began to restore the ancient military rules, to enforce discipline, and to reorganise such an army as might be able to keep the barbarians in check. The demoralised soldiery could not endure the change. A conspiracy was formed against him, and the youthful emperor was murdered in his tent, in his twenty-ninth year, after a short but glorious reign of thirteen years.

A.D. 235.

Maximinus.

The sceptre was now seized by the chief instigator of the mutiny, Caius Julius Maximinus, by birth a Thracian peasant. He was a man of gigantic stature and strength, indefatigable hardihood, and great personal daring; but to the wily cunning added the savage ferocity of an ignorant barbarian. He began his reign by murdering all the friends of the late emperor, and sent orders to the senate to ratify his bloody deeds. Having thus, as he thought, fixed himself firmly on the throne, he prosecuted the war against the Germans with great success, routed them in several battles, and devastated an immense extent of the country, selling the inhabitants for slaves. He next marched against the Sarmatians and the Dacians, over whom he gained several victories; and elated with success he was resolved to subdue their country, till he should reach the northern ocean. But an insurrection arose in Africa, caused by his insatiable avarice, and Gordian, proconsul of Africa, was proclaimed emperor. On receiving this intelligence, Maximinus quitted Sirmium and began his march towards Italy, resolved to glut his savage heart with vengeance. In the meantime, Gordian was defeated and slain by Maximinus's lieutenant; but the senate, knowing it in vain to expect mercy, chose as emperors, Balbinus and Pupienus, who, to gratify the people, gave the title of Cæsar to the youthful Gordian, a boy of twelve years old. Maximinus had by this time entered Italy, and laid siege to Aquileia. He met with a gallant resistance; and his own troops suffering excessively during the siege, mutinied, and slew him while he lay asleep in his tent.

D. 238.
rdian.

The death of Maximinus left the throne in the possession of the youthful Gordian, and prevented the horrors of a civil war. But the empire continued to be assailed by the restless hordes of barbarians, the Carpi, who had crossed the Danube, ravaging the province of Moesia, while the Persians were invading the eastern dominions. In this emergency, Gordian was ably supported by his father-in-law, Misitheus, præfect of the prætorian guards, who possessed at once the qualities of a statesman and a general. Sapor, the second prince of the new Persian dynasty, the Sassanides, had made some daring and successful inroads upon the Roman dominions; but the emperor, aided by the skilful support of Misitheus, drove back the invaders, defeating them in every encounter, and penetrating to the very heart of their territories. These successes were dearly purchased by the death of the wise and brave Misitheus, to whom they are chiefly ascribed. Gordian appointed Philip the Arabian to the station vacant by the death of Misitheus; and prosecuted the war with undaunted courage and undiminished success. But Philip found means to raise in the army such a mutiny as could not be subdued, without his elevation to an equality with Gordian in the empire. This success in guilt stimulated Philip to additional crimes for the promotion of his lawless ambition, and he rested not till he procured the murder of this young emperor, who was giving such proofs of ability, and such promise of future excellence.

A.D. 244.

Philip.

Philip, to secure his tenure of power, concluded a peace with the Persians, and hastened to Rome, where he endeavoured to persuade the senate that the death of Gordian was caused by disease. He did not long enjoy his sovereignty undisturbed. Insurrections of a formidable character broke out in different parts of the empire, especially in Pannonia. Trajanus Decius, whom Philip had sent to suppress this insurrection, had scarcely reached his army when he was compelled to assume the imperial diadem. Philip marched against his unwilling antagonist, but was defeated and slain near Verona. In the reign of Philip the secular games were celebrated, in what was computed to be the one thousandth year from the foundation of the city.

A.D. 249.

Trajanus Decius.

Great persecution of Christians.

The reign of Trajanus Decius is memorable on two accounts. Its annals are stained by one of the most sanguinary persecutions that ever tried the sincerity and zeal of the Christian church. Almost innumerable multitudes of Christians were banished, imprisoned, or tortured to death with the most relentless cruelty. The revolution in Persia, which established the dynasty of the Sassanides, restored the worship and the tenets inculcated by the followers of Zoroaster; and caused the retreat of the Asiatic Christians into the dominions of the Romans, at that time more tolerant. But these Asiatic Christians brought with them many of the notions peculiar to the East, and thus gave rise to dissensions among the Christians themselves. Decius, a man of stern and unaccommodating temper, determined to put an end to all such discussions, by completely suppressing Christianity itself; and he published a bloody edict, prohibiting all innovations in religion, and strictly enjoining compliance with the ancient idolatrous worship of Greece and Rome. The horrors occasioned by this cruel edict could not be enumerated, and it is not our province to make the attempt. But it ought to be mentioned that the ascetic and mystic notions prevalent in the East, when driven to excess by this persecution, induced numbers to betake themselves to wild and desert solitudes to seek for safety; and from this excessive development of the ascetic spirit at length arose the monastic, that fertile source of so many errors and abuses.

Goths.

The other memorable event in the reign of Decius, is the first appearance of the Goths among the contending nations by whom the Roman empire now began to be regarded as a common enemy, or rather perhaps as a common prey. The origin of this mighty people is involved in deep obscurity, which the utmost researches of learned men have not been able entirely to remove. The most probable opinion, however, appears to be, that which regards them as a powerful branch of the great Indo-Teutonic race, by which both northern Asia and northern Europe were peopled, at some indefinitely remote period, before which the southern districts had already been inhabited, very probably by the Pelasgian race. After having been settled for ages in Scandinavia, they appear to have resolved on a southern migration, passed along the lower shore of the Baltic, followed the course of the Borysthenes, (Dnieper,) and the Tanais, (Don,) and took possession of the Ukraine. Thence they afterwards directed their course south-west, ravaged the province of Dacia, and crossing the Danube, appeared in great strength in Mœsia. When information respecting these new and formidable invaders was carried to Rome, Decius immediately marched against them. He was worsted in the first engagement, and the Goths succeeded in taking Philippopolis; but Decius having recruited his forces, defeated them, and reduced them to the utmost distress. It was his aim to inflict upon them such an overthrow as should deter them from renewing their invasions of the empire. A battle was fought, in which the Goths, animated with the terrible energy and courage of despair, and being skilfully posted on the edge of a morass, resisted all the efforts of the Roman forces to break them; and young Decius having fallen, the emperor, eager to revenge the death of his son, plunged furiously into the morass, sunk struggling into its absorbing depth, and disappeared. The Roman army suffered an immense loss, but the Goths were in no condition to prosecute their victory.

A.D. 251.

Gallus.

Gallus was proclaimed emperor by the surviving army, and having immediately concluded a dishonourable peace with the Goths, hastened to Rome to enjoy the gratifications of unrestrained indulgence. His son Voluscan he created Cæsar, and contrived to get the son of Decius into his power, and put him to death. His conduct excited a general indignation against him; and at length Æmilianus, commander of the forces in Mœsia, raised the standard of revolt against him. A battle was fought, in which Gallus was defeated and slain, his son sharing his fate. In three months, Æmilianus himself was deposed and killed, the army declaring in favour of Valerianus, general of the army stationed in Gaul.

A.D. 253.

Valerian.

Of Valerian, who had been distinguished by his virtues while in a private station, great expectations were formed. Having appointed his son Gallienus to be his associate in the empire, he left him to defend it against the incursions of the Goths and Germans, and marched to the East to oppose the Persian king Sapor, or Shah Pur. Valerian was defeated and taken prisoner by the Persians, who treated him with great and contemptuous cruelty. His degenerate son Gallienus made no effort to obtain his release, being apparently more satisfied to reign alone.

A.D. 259.

Gallienus.

The captivity of Valerian, and the accession of the feeble Gallienus, seemed to be the signal for a universal assault upon the defenceless empire. It was invaded on all sides by the hostile barbarians, who seemed to vie with each other in striving for the honour of being the destroyers of Rome. Several victories over the Germans were gained by the generals of Gallienus; but each army resolving to make its own general emperor, a period of hopeless and helpless anarchy ensued, which threatened the immediate disruption of the empire. The host of competitors which thus sprung up in all quarters, is known by the designation of "the thirty tyrants," though not actually amounting to so many. The very number of these contending rivals impeded the success of any, no one being possessed of sufficient power to strike a decisive blow. At length Gallienus was killed while besieging Aureolus, one of the usurpers, in Milan.

A.D. 268.

Marcus Aurelius Claudius.

He was succeeded by Marcus Aurelius Claudius, a man of great courage, skill, and virtue, capable of upholding the tottering state of the empire. He soon defeated Aureolus, then overcame the Germans, and next routed the Goths in a great battle at Nissa. His attention was next directed to the affairs of the East; but while making preparations for his march thither, he was seized by a pestilential disease, of which he died at Sirmium, after having reigned two years.

A.D. 270.

Aurelian.

A feeble attempt to obtain the imperial power was made by the brother of Claudius, which terminated after the lapse of seventeen days, by the unfortunate victim of ambition becoming his own executioner. The army now made choice of Aurelian, a native of Sirmium, the son of a peasant of that country, and raised to high military rank and fame by his own surpassing merits. It was reserved for this distinguished man to show what could be accomplished by an imperial hero. The hopes of the Goths had revived on the death of Claudius, and they had renewed their invasion. They were met by Aurelian, and a bloody battle was fought, to which night, not victory on either side, gave a temporary suspension. Wearied with mutual slaughter, both parties were averse from renewing the undecided combat, and a treaty was formed, by which Aurelian consented to relinquish that part of Dacia which lay beyond the Danube, and to make the river the boundary of his empire in that direction. The Goths furnished a body of cavalry as auxiliaries to the Romans, and engaged to abstain from future invasion. By this treaty, Aurelian strengthened the Roman empire in that quarter, obtaining a well-defined boundary, and leaving to the enemy a devastated region, no longer worth defending.

The Alemanni, in the mean time, had entered the Roman dominions, and laid waste the country along the Po. Aurelian marched rapidly against them, inflicted on them several sanguinary defeats, and freed Italy from the terrors of the barbarian invaders. The Vandals also sunk before his matchless valour and conduct; and having now secured the western part of the empire, he directed his arms against the east, to encounter a female antagonist.

Zenobia queen of Palmyra.

This was the justly celebrated Zenobia (Zeinab) queen of Palmyra, widow of Odenathus, who had been one of the numerous claimants of imperial honours during the reign of Gallienus, and to whom that easy monarch had been willing to grant the title of his colleague. Palmyra, or Tadmor, is stated in the Bible to have been built by Solomon. The situation of that beautiful spot, a green island in the midst of a sandy ocean, and almost equidistant between the Euphrates and the Phœnician coast, pointed it out to the wisest of kings as a suitable place for commercial enterprise, and admirably adapted to promote his great idea of changing the line of intercourse between the east and the west, from the Red Sea to the Euphrates, and rendering Palestine, not Egypt, the great emporium of nations. After the decline of the kingdom of Israel, this idea seems to have been relinquished; but still Palmyra continued to form an excellent intermediate station between the Euphrates and Asia Minor, for the caravans employed in the Indian and Arabian trade. It thus grew in wealth, if not in political power or importance, yielding ready obedience to the great dominant empires, each in its turn, and seeking nothing from them but protection. From the Parthians it seems to have suffered no injury; but the revolution which gave central Asia to the Sasanide dynasty, involved Palmyra in the general warfare. Odenathus, said by some to have been an Arab Emir, was one of the most considerable of the inhabitants of Palmyra. Irritated by the insults of the Persians, and instigated by his high-spirited wife, Zenobia, he headed his countrymen in their resistance to the plundering bands of the Persian king, successively defeated them, and acquired sufficient power not only to rescue Palmyra, but even to carry the war into the enemy's country, and to advance to the gates of Ctesiphon. In a short time all Mesopotamia and Syria owned his sway, and he was acknowledged as colleague by Gallienus. Odenathus having been cut off by private treachery, the falling sceptre of Palmyra was immediately seized by Zenobia, who wielded it with no timid or feeble hand. For the space of six years did she maintain her sway, and even added Egypt to her dominions, justifying the proud title she had assumed, Queen of the East. Such was the woman against whom Aurelian thought it no disgrace to lead in person his Roman legions.

The result was what might have been anticipated. Zenobia was defeated in two successive and bravely-contested battles; Palmyra was besieged, and after a gallant resistance, its own resources being exhausted, it was compelled to capitulate, and Zènobia was taken prisoner while attempting to make her escape into Persia. Scarcely had

Roman History.

Aurelian withdrawn his forces, when the Palmyrenians again revolted; and the angry conqueror having again made himself master of this city of romance, reduced it to ruins, of which the extent, beauty, and magnificence still amaze the traveller. Among the victims of the emperor's wrath was Longinus, the secretary of Zenobia, and the reputed author of an admirable treatise on the sublime. Having thus reduced and destroyed Palmyra, he suppressed an insurrection in Egypt, and returned to Rome, where he celebrated his victories and conquest by a triumph the most remarkable that the city had ever witnessed. Zenobia, who had been compelled to grace this triumph, by walking on foot in the train of her conqueror, received afterwards from him a small estate at Tibur, where she spent in tranquillity the remainder of her life as a Roman matron, leaving a family which was not extinct in the fifth century. A.D. 271.

A violent sedition soon afterwards arose at Rome, in consequence of an attempt by Aurelian to debase the coinage. It was followed by so much bloodshed, and gave so much offence to the emperor, that his native sternness, and the pitiless decision of a warrior, degenerated into harshness and cruelty. Being again obliged to lead his army against the Persians, he left the city, and sought the more congenial pursuits of war; but was afterwards assassinated at the instigation of his private secretary Mnestheus. The murderers were torn to pieces by the enraged soldiery, who almost adored their warlike emperor. A. D. 275.

Nothing can better prove the effect of the masculine government of Aurelian, and the regulated subordination which it had given to the troops, than the fact that the army actually allowed six months to pass in tranquillity, while they awaited the election of an emperor by the senate. That body at length elected Marcus Claudius Tacitus, an aged senator of high character, and a decendant of the celebrated historian of that name. He had scarcely begun to prove the wisdom of their choice, by the enactment of some salutary laws, when he was compelled to march against the Alani, a Scythian tribe, who were devastating Asia Minor. He was successful in the war; but the fatigues and anxieties of the campaign were too severe for a frame already enfeebled by age, and he died in Cappadocia.

acitus.

D. 276.

lorianus.

The imperial diadem was immediately assumed by Florianus, brother of the late emperor; but the Syrian army chose Marcus Aurelius Probus, a general of great and varied merit, to be the successor to the throne. Florian finding himself opposed by a man against whom he could not hope for success, put an end to his own life, and thus left the empire to his rival.

obus.

Closely resembling Aurelian in personal bravery, and, like him, also a native of Sirmium, Probus began a reign scarcely less warlike and glorious than that of his great countryman. He defeated the Germans in several battles, and drove them beyond the Rhine and Danube, which were now considered the natural limits of the empire. To complete the boundary-line in that quarter, he constructed a strong wall from the Danube to the Rhine. Passing along the northern frontier of the empire, he reduced the Goths to quiescence, entered Asia, and led his army against Varames (Bahram) king of Persia. That monarch not daring to encounter the hardy veterans of Probus, consented to a peace of which the terms were dictated by the emperor. Three competitors next fell before his power, and he now seemed at leisure to cultivate the arts of peace, for which he had a strong natural predilection. He accordingly employed his legions in draining pestilential fens, planting vineyards, and improving instead of devastating the face of the country. This restoration of the ancient and wise military discipline of earlier and more virtuous days, gave offence to the licentious soldiery; who mutinied and slew the brave and good emperor. D. 282.

Roman History.

Reverting to the custom formerly so prevalent, the army proclaimed as emperor Carus, prefect of the prætorian guards, and the senate reluctantly ratified their choice. In the hope of promoting tranquillity, and securing the inheritance of the imperial dignity in his own family, Carus gave the title of Cæsar to his two sons, Carinus and Numerianus, who were thus his appointed successors. He led his army against the Goths, who had renewed their predatory incursions, and defeated them; but was prevented from following up his victory in consequence of a new invasion of the Persians. Leaving Carinus to protect the western provinces, and taking Numerianus along with him, he marched into Asia, and gave the Persians a complete overthrow. Pursuing the defeated enemy, he entered their own country, advanced to Ctesiphon, and began the siege, when he was killed in his tent, some authors say by a flash of lightning, more probably by some secret conspiracy. A. D. 283.

Numerianus.

Numerianus was acknowledged by the army as his successor; but his gentle and pacific disposition exposed him to the ambition of Aper, præfect of the prætorian guards, by whom he was privately murdered, and his death was concealed till the traitor might have time to secure his own elevation. But the bloody deed being discovered, a tumult arose in the army, in the midst of which Diocletian slew Aper, and was proclaimed emperor in his stead. He did not, however, at once obtain undisputed possession; for Carinus, hearing of his brother's death, assembled a powerful army, and began his march against the usurpers. On his way he encountered and defeated another rival, Julianus, and advancing into Mœsia, was met and opposed by Diocletian. The troops of Diocletian, however, were unable to contend with the hardy veterans of Carinus, who gained the victory, but was slain in the moment of his success by a tribune, to avenge the violated honour of his wife; and thus, though defeated, Diocletian remained in possession of the diadem. A. D. 284.

Diocletian and Maximian.

The reign of Diocletian is one of much historical importance. It was rendered conspicuous by the introduction of a new system of imperial government, and by the last and greatest persecution of the Christians. Very soon after his accession to the throne, Diocletian, feeling the weight of the imperial government greater than he was disposed to bear alone, chose as his colleague Maximianus, who had been his companion in arms, and to whom he was willing to delegate the chief part of the military cares. Maximian had soon an opportunity of using his power and displaying his courage, in consequence of an insurrection in Gaul. This insurrection he speedily suppressed, and obtained some victories over the German invaders of the province. In the mean time, Diocletian had been equally successful against the Sarmatians and the Persians. But scarcely had they obtained these victories, when new disturbances and new invasions broke out in every part of the wide empire, the wandering nations pressing inwards from all quarters, and threatening to crush the entire Roman power. To make head against so many invading armies seemed impossible, without a further division of power. For Diocletian seems to have entertained the opinion, that to entrust large armies to experienced commanders was only to put it in their power to become aspirants for the throne; and that the only way to secure their fidelity was to give them such a share in the imperial government as should engage their own interest in its preservation. A. D. 286.

In pursuance of this scheme, he induced his colleague Maximian to name as his Cæsar and successor Constantius Chlorus; while he himself chose Maximinus Galerius. In this choice Diocletian was apparently guided by the same A. D. 292.

principle which had led to his selection of Maximian as his own colleague, the principle of dissimilitude. A man comparatively peaceful himself, he chose to be associated with Maximian, a rough warrior: to this rugged Augustus, or emperor, he assigned a peaceful and mild Cæsar, Constantius, again choosing for his own Cæsar the warlike and fierce Galerius. A new division of the empire followed. Diocletian took the eastern provinces; Galerius was appointed to Thrace and Illyricum; Maximian received Italy and Africa; and Gaul, Spain, and Britain, were entrusted to Constantius. Each of the Cæsars, although they differed in their dispositions, was a man of courage and military experience; and for a time the arrangement seemed productive of the very best consequences, but it ultimately tended to hasten the dismemberment of the empire and its consequent overthrow.

British war.

Constantius, to whom Britain had been assigned, had to begin his tenure of power by a war for its possession. The usurper Carausius had several years before raised himself to the chief command in Britain, which he retained in spite of the efforts of the imperial generals. He was slain by Allectus, a new usurper, just as Constantius was preparing to cross from Gaul against him. Constantius speedily defeated Allectus, and gained the complete possession of his province, which he maintained with equal valour and moderation, governing with such justice as to make himself equally beloved by his army and the native inhabitants. In the mean time, Galerius was equally successful on the Danube, where he defeated the invaders; Maximian in Africa, and Diocletian in Egypt; so that this division of power seemed to secure the defence of the empire, by enabling its rulers to oppose every new assailant. A war against the Persians threatened more disastrous consequences. Diocletian had sent for Galerius to conduct this war; but in the first battle the Persians gained the victory, and inflicted on the Romans a very severe defeat. Next year Galerius, at the head of a more powerful army again invaded Persia; but profiting by experience, he kept his forces on the hilly regions of Armenia, where the Persian cavalry could not act, and watching his time, rushed like a mountain torrent on the Persians, and gave them a terrible overthrow. The rout was complete and irrecoverable, and so greatly were the Persians dispirited, that they were glad to yield to the conditions of peace offered by the conqueror. The province of Mesopotamia was ceded to the Romans, and the Tigris again became the eastern boundary of the empire.

Persian war.

Great persecution of the Christians.

These successful wars might have been followed by a period of peace and prosperity; they ushered in scenes of unparalleled atrocity. Diocletian had made the city of Nicomedia the seat of his residence; and there he maintained a court of eastern splendour, to which he invited men of learning and philosophy. But the philosophers who frequented his court being all animated with extreme hatred against Christianity, exerted themselves in instigating the emperor to extirpate a religion too pure and lofty to suit their polluted minds. Galerius is said also to have stimulated Diocletian to undertake the destruction of a religion, the gentle and peaceful spirit of which he could neither understand nor appreciate. Three imperial edicts were successively published, requiring the books of the Christians to be everywhere sought for and burned, forbidding them to meet together for the purpose of religious worship on pain of death, inflicting punishments of every kind, imprisonment, slavery, infamy, and death upon all the dignitaries of the church, and sanctioning the employment of every possible method to produce, enforce, or compel apostacy, and a return to the established idolatry of the empire. The barbarities which followed upon the issuing of these edicts were utterly inconceivable. Malicious ingenuity was racked to the utmost to devise tortures for the persecuted followers of Jesus. For the space of ten years did this persecution rage with scarcely mitigated horrors; and such multitudes were massacred in all parts of the empire, that at last the imperial murderers ventured to erect a triumphal column, bearing the barbarously boastful, yet false inscription, that they had extinguished the Christian name and superstition, and restored the worship of the gods to its former purity and splendour.

A.D. 303.

The scheme of this great and bloody persecution was devised by the emperor Diocletian and his Cæsar Galerius, during a winter residence in the palace of Nicomedia. Soon after the issuing of the persecuting edicts, Diocletian repaired to Rome, and there, along with his colleague Maximian, enjoyed the honours of a triumph for the various victories which had been gained in their joint sovereignty. This was remarkable as the last triumph that ever entered the proud gates of Rome. Diocletian had already set the example of a residence in the provinces; and other causes soon conspired to render this example both common and expedient, so that Rome ceased to be the capital of even the Roman world. Wearied with the cares of government, offended with the rude freedoms of the citizens of Rome, and feeling the effects of advancing age, Diocletian began to entertain serious intentions of abdicating the imperial power. These intentions were confirmed by a severe illness under which he laboured, after his return to Nicomedia; and at length he prevailed on his reluctant colleague Maximian to accompany him in his abdication, as he had in his assumption of the toils and the honours of sovereign dominion. Accordingly, the two emperors formally relinquished the imperial station, power, and titles; and were succeeded by Galerius and Constantius, who now from being Cæsars, became each an Augustus. A new division of the empire necessarily followed, of which Galerius seized the lion's share, without however provoking any hostile opposition from Constantius. Galerius retained all the eastern provinces, together with Italy and Africa; Constantius was satisfied with the possession of Spain, Gaul, and Britain. Galerius appointed two Cæsars, Severus, to whom he consigned Italy and Africa, and Maximin, to whom he entrusted the Asiatic provinces. Diocletian survived his abdication about nine years, which he spent in tranquillity, ease, and luxurious retirement at Salona (Spalatro), amusing himself in the erection of a magnificent palace, and the calm pleasures of rural and horticultural pursuits, resisting every attempt to induce him to return to the paths of ambition, and declaring that he had never known the true enjoyment of life till after his resignation of power.

Last Roman triumph.

A. D. 30

Galerius and Constantius.

Constantine, son of Constantius, was detained for some time by Galerius, who was apprehensive of danger from the talents of that young prince; but he contrived to escape, and by a rapid flight secured his safety, and joined his father in Britain, who was preparing to march against the Scots and Picts, as the inhabitants of the northern regions of that island now began to be called. While Constantius was on his march northwards, he was seized with a mortal illness, and died at York, having nominated as successor, his son Constantine, who was accordingly saluted Augustus by his army. Galerius refused to ratify this elevation to the imperial dignity of a prince whom he at once hated and feared; but sanctioned his being termed a Cæsar, bestowing the now vacant rank of Augustus upon Severus, one of his own Cæsars. This dignity had been expected by Maxentius, son of the abdicated emperor Maximian. Indignant at his disappointment, Maxentius caused himself to be proclaimed emperor by his army; and to colour this usurpation, he induced his father to leave his retreat, and resume the imperial title. A scene of contention followed, scarcely paralleled in the annals of Rome. Severus march-

A. D. 30

ed against the two usurpers; but was abandoned by his own troops, yielded, and was slain. Galerius levied a great army, and marched into Italy against Maximian and Maxentius; who, dreading his power, retired to Gaul, and endeavoured to procure the support of Constantine. This politic prince did not consider it expedient to provoke a war at that time, and for no better cause; and Galerius having withdrawn from Italy, and returned to the east, Maximian and Maxentius returned to Rome. To aid him in the struggle, Galerius conferred the title of emperor on his friend Licinius; and thus there were at once six pretenders to the sovereignty of the empire, namely, Galerius and Licinius, Maximian and his son Maxentius, Maximin, who had been nominated Cæsar by Galerius, and Constantine, the son and successor of Constantius. Among these rivals, Constantine possessed a decided superiority in prudence and abilities, both military and political.

. D. 307.

The harsh temper of Maximian soon led to a quarrel between him and his son Maxentius; and finding himself unable to obtain an ascendancy over one who was no less intractable than himself, he quitted Rome, and went to Gaul to Constantine. There also he found himself disappointed of that power which he so greatly longed to possess, and began to plot against the life of Constantine, his son-in-law. But being detected, he was condemned to death, the only favour shewn to his age and former dignity being permission to choose in what manner he should die. Thus perished one competitor for the throne. Nor did Galerius long survive him. A loathsome disease, contracted by excessive indulgence in habits of sensuality, brought his turbulent life to its termination, leaving his power to be divided between his Cæsars, Maximin and Licinius. There were now four rivals contending for the empire, Constantine, Maxentius, Maximian, and Licinius. Maxentius speedily provoked open hostilities with Constantine, who marched at the head of a powerful army towards Rome.

D. 310.

D. 311.

stan- de- es him- a istian, D. 311.

It was while Constantine was proceeding on this momentous expedition, that he made an open and public declaration in favour of Christianity. Before that time, the persecuting edicts of Diocletian had been much mitigated by the forbearance and leniency of Constantius; and Constantine not only followed his father's example, in being merciful to the persecuted Christians, but even shewed them some marks of positive favour. Very considerable numbers of them, in consequence, flocked to his standards, and swelled the ranks of his army. Their peaceful, orderly, and faithful conduct, contrasting most favourably with the turbulent and dissolute behaviour of those who formed the mass of common armies, won his entire confidence. To what extent this led Constantine to form a favourable opinion of Christianity, or inclined him to view with esteem and respect tenets which had produced such results, cannot be ascertained. How far his avowed reception of Christianity was influenced by the prudence of the politician, how far by the convictions of the convert, it is impossible to determine. The accounts of his dream, and his vision, which united to enforce his trust in Christianity, bear too much the aspect of fiction, or of having been the illusive consequences of mental anxiety, brooding intensely on the possible results of a great religious revolution, to be woven into the narrative of sober history. This, at least, is certain, Constantine caused the *cross* to be employed as the imperial standard, and advanced with it to promised victory.[1]

After the armies of Maxentius, led by his generals, had sustained two successive defeats, he found it imperatively necessary to rouse himself from his sensual and inactive life at Rome, and to advance against his formidable assailant. He accordingly mustered a very numerous army, put himself at its head, marched out of Rome, and met the host of Constantine near the little river Cremera, about nine miles from the city. A dreadful encounter took place, both parties being stimulated by every motive that could animate men to erect the utmost energies of mind and body. It was not merely a battle of emperors; it seemed also a strife of religions. At length the troops of Maxentius gave way, wavered, broke, and fled in headlong and irretrievable confusion; Maxentius himself, endeavouring to enter the city by the Milvian bridge, amidst the crowd of fugitives, was precipitated into the Tiber, and perished, partly weighed down by his armour, and partly encumbered and overwhelmed among numbers of struggling wretches, whose dying gripes knew not to respect the purple.

A. D. 312.

Constantine and Licinius.

Constantine entered Rome victorious, restored to the senate their authority, disbanded the prætorian guards, and destroyed their fortified camp, from which they had so long awed the city and given rulers to the empire. After a brief stay in Rome, he proceeded towards Illyricum to meet Licinius, with whom he had formed a secret alliance before marching against Maxentius. The two emperors met at Milan, where their alliance was ratified by the marriage of Licinius to Constantine's daughter. During this calm interview, Constantine prevailed upon Licinius to consent to the repeal of the persecuting edicts of Diocletian, and to the issuing of a new edict, by which not only the sanguinary enactments of the former emperor were revoked, but Christianity was encouraged, its religious teachers were honoured, and its adherents advanced to places of trust and influence in the state.

A. D. 313.

This placid and beneficial intercourse between the emperors, was speedily interrupted by an irruption of the Franks into Gaul, to which they afterwards gave their name. Constantine hastened to oppose them. Anxious to take advantage of this opportunity to crush separately the two emperors, whom united he could not match, Maximin made a very rapid march against Licinius, and almost succeeded in overpowering him unawares. Licinius, however, kept his enemy at bay till he had mustered sufficient force, and then gave him a total overthrow near Adrianople. Maximin fled almost alone to Nicomedia, and there died, either of poison or of mortified rage and despair.

A. D. 313.

The peace, which had seemed to be established on so firm a foundation between Constantine and Licinius, was soon interrupted. A war, conducted with great skill and courage on both sides, arose for the sole supremacy of the empire. But the activity, talents, and enterprise of Constantine prevailed. Licinius was defeated in a bloody battle near Sirmium; but though defeated, he was not overpowered. He speedily rallied the remains of his beaten army, mustered fresh forces, and again met his rival in the field, again to sustain another and a more complete discomfiture. Through the intervention of Constantine's daughter, an agreement soon afterwards took place, by which the provinces south of the Danube were ceded to the conqueror, and the dominions of Licinius limited to the Asiatic regions. For about eight years a sort of uneasy peace continued between the two rival emperors, Licinius feeling, and hating to feel, the natural superiority of Constantine. Another open rupture was unavoidable; and both parties now made preparations for a contest, the issue of which should be final. The two hostile armies met on the banks of the Hebrus, near Adrianople. Licinius had taken up a strong and advantageous position, in which he waited the attack of his adversary. For some days the two armies lay and watched each other's evolutions. At last Constantine with great skill drew his enemy from his position, and forced him to an encounter on equal terms. The battle was fierce, obstinate, and sanguinary; but the commanding genius, and heroic courage of Constantine secured him a complete victory. The spirit of Licinius was still unbroken. The siege of

---

[1] It is not necessary to attempt any explanation of the celebrated dream and vision of Constantine, which have so much engaged the attention of both ecclesiastical and infidel historians. The circumstances, according to the best authorities, were the following. While he was marching towards Rome against Maxentius, at the head of his army, on a sudden there appeared in the air, about noon-day, a luminous cross, bearing the following inscription: 'Εν τούτῳ νίκα, BY THIS CONQUER. During the ensuing night, he was directed in a dream, to frame a standard resembling the vision he had seen, and to inscribe on it, and on the shields of his soldiers, the *labarum*, or monogram of the sacred name of Christ. That such a standard was at that time used, and that Constantine conquered, are historical facts beyond dispute; for the reality of the dream and the vision, we must refer to the testimony of the emperor himself, and of contemporaneous historians.

A. D. 324.

Byzantium detained Constantine, and allowed his antagonist to muster all his remaining strength, in order to strike one more blow for life and empire. Chrysopolis was the scene of the decisive conflict. But the raw levies of Licinius could not withstand the conquering veterans of Constantine; the struggle produced rather a carnage than a battle, and the utter annihilation of his last army left to Licinius no resource but unconditional submission. He was deprived of his imperial honours, and permitted to retire to Thessalonica, there to pass the remainder of his days in obscurity and inglorious ease. But the life of a dethroned monarch is not usually long. He was accused of tampering with the barbarians, and conspiring with their aid to rekindle the flames of war. Such an accusation was of itself enough to cause sentence of death to be pronounced; it was immediately put in execution, and the empire was once more transmitted to the sway of a single emperor.

Constantine.

Constantine, thus possessed of supreme power, immediately put in force some of those important purposes which had long engaged his thoughts. He issued several edicts for the suppression of idolatry; and at the same time restored to the Christians both the churches and the property of which they had been deprived during the last persecution. We have not sufficient information to enable us to judge accurately respecting the intentions of Constantine, or respecting the power of circumstances in obliging him to modify his own schemes, so as to adapt them to certain events which he could not altogether mould. But it is scarcely possible to ascribe too much to the deep policy of this emperor. He was well aware of the characters of the two conflicting religions, Christianity and Paganism. He had also marked with discriminating eye the deep degeneracy of Rome and its inhabitants. Neither had the consequences of the partition of the empire by Diocletian escaped his politic observation; and if the hope of preventing its final dissolution was to be cherished, he saw it to be indispensably necessary to attempt a reconstruction of the empire, upon an arrangement entirely new. The whole fabric of the ancient constitution of republican Rome had been pervaded by its religious worship and institutions. It was natural for him to determine that the new constitution of the renovated empire, should be pervaded by the worship and the institutions of Christianity. And as these had already attained a considerable degree of maturity, he adopted them as they were, partly perhaps because he durst not venture to offend the Christians by any attempted reformation, or reconstruction; partly because the state of his own religious knowledge, so far as we have any means of judging, was very inadequate and imperfect.

Establishment of Christianity.

Being resolved to give a new constitution to the Roman empire, and to make Christianity its basis and ruling principle; being at the same time aware of the inveterate force of the associations connecting every thing in Rome with its ancient idolatrous worship, enhancing immensely the difficulty of making any immediate and thorough change there; and having before him the example of Diocletian, Constantine resolved to change the seat of empire, in order to facilitate his change of the imperial constitution. The most formidable enemies of the empire had for a considerable time been the Goths and the Persians; and the necessity of being nearer to the scene of danger, may have led to the idea of selecting an eastern situation for the new seat of government. The siege of Byzantium, which Constantine had formerly conducted in person, probably directed his attention to that city, as the most eligible situation; and it must be owned that it possesses advantages almost unequalled, as the seat of an empire both European and Asiatic. On it accordingly the emperor fixed his choice; and receiving from him immense additions and embellishments, together with a new name, it became *Constantinople*, the new imperial city.

Seat of empire transferred to Constantinople.

Previously, however, to this great change in the seat of government, there had been held a general council of the Christian teachers at Nice, for the purpose of determining the Arian controversy, which the emperor attended in person; and where he obtained the opportunity of making such enactments respecting the civil constitution of the church, as he either deemed it expedient, or found himself enabled to make. But the controversies which at that time, and for a long period afterwards, divided the church, furnished unhappily the means, and set the precedent, of persecutions conducted by one body of Christians against another; and in which both were too ready to sacrifice their spiritual independence, for the purpose of obtaining the aid of the civil power in crushing their antagonists.

A. D. 3

A. D. 3

In the arrangements of his new imperial constitution, Constantine adopted much of the pomp and ceremony of an Asiatic court. A complete disjunction between civil and military authorities took place; and all the great officers of state were modelled anew, with new titles suited to the new arrangements, as officers of the court, of the army, and of the civil department. The officers of the court and of state, were chiefly the lords or counts of the bed-chamber and the palace *(comites cubiculi, et palatii)*, and the ministers of the interior, of the finances, of justice, of the crown-treasury, and of the household troops, or body guards. The officers of the army were the general-in-chief, and the generals of cavalry and of infantry; the next class were the counts and dukes *(comites et duces)* of the army. The civil department was divided into four great *præfectures*, each had its *diocese*, and each diocese its *province*, administered by *præfecti prætorio*, *vicarii*, and *rectores provinciarum*, which officers had no military authority, as the military and state officers had no civil power. A new system of taxation was also established, consisting chiefly of a land-tax, a tax upon trade, and the obligatory enforcement of what had formerly been a free gift to the emperor upon extraordinary occasions. Such is a very brief outline of the new constitution given by Constantine to the empire, obviously more Oriental than European or Roman in its character.

New co stitution the emp

Notwithstanding the Asiatic aspect thus imparted to his government, Constantine retained his ability and readiness for war, when enemies dared to insult his dominions. Several defeats repressed the hostile invasions of the Sarmatians and Goths, who had renewed their attempts upon Thrace; and the Persian monarch did not venture to provoke the power of an emperor equally renowned for his military and for his civil virtues. Disease at length assailed a frame that had been long and severely tried by the toils, cares, and indulgences of imperial state; and after being openly admitted by baptism into that church of which he had been so long an avowed adherent, he expired in the thirtieth year of his reign.

A.D. 337. Constantine. Constantius. Constans.

The three sons of Constantine had been named Cæsars by their father, and on his death they divided the empire among them. Constantine obtained Gaul, Spain, and Britain; Constantius, the Asiatic provinces, with the capital, Constantinople; and Constans, Italy and Africa. The late emperor had assigned provinces to his two nephews, Dalmatius and Hannibilianus; but the three new emperors, on the ground of a false accusation, barbarously murdered their uncles, cousins, and every member of the imperial house, except two cousins, Gallus and Julian, one suffering under a hopeless malady, the other a mere child. This bloody deed did not long secure to the brothers the quiet possession of their dominions. A dangerous war arose in the East, where Constantius was unable to resist the growing power of the Persians, but suffered several heavy defeats, and was in danger of losing the whole of Mesopotamia, when the Persians were obliged to offer a peace, in consequence of their own dominions being assailed by the nomad tribes beyond the Oxus.

Death of Constantine. A.D. 340.

In the mean time, ambition had kindled a war between the other two imperial brothers, Constantine and Constans. Not satisfied with his portion of the empire, Constantine first seized upon Africa, and then attempted to wrest Italy from Constans. He crossed the Alps, and began to ravage the country round Aquileia; when falling into an ambuscade he was slain, together with the greater part of his troops. Constans immediately took possession of his fallen brother's dominions, and thus became the sovereign of two-thirds of the empire. Satisfied, apparently, with this great acquisition, he plunged into the most dissolute indulgences, refused to cede any portion to Constantius, and even allowed that prince to wage an unequal war against the Persians, refusing to lend him any assistance. At length his general, Magnentius, raised the standard of revolt. Constans fled towards Spain, but was overtaken and killed near the Pyrenees.

Death of Constans. A.D. 350

While Constantius was preparing to avenge the death of his brother, a new revolt broke out in Illyricum. The army of that province compelled their general, Vetranio, to assume the purple; and Constantina, sister of the emperor, encouraged him to the deed, and even urged him to form an alliance with the usurper Magnentius, who had so recently slain her brother Constans. Not deeming it prudent to engage in a war of such magnitude without providing for the administration of affairs during his absence, Constantius placed his cousin Gallus in the rank of Cæsar, and advanced to Constantinople, which Vetranio had seized while the emperor was engaged in the Persian war. Pretending to be willing to admit Vetranio to an equal share of power with himself, he obtained permission to enter the imperial city; and immediately roused the feeling of the army and the people so far, that they declared him sole emperor. Vetranio quietly submitted, his life was spared, and he retired to Prusa, where he spent the remainder of his life in calm seclusion. Maxentius, fully determined to maintain his usurped power, marched at the head of a strong army into Pannonia to meet Constantius. The hostile forces came to an encounter on the plains of Mursa, and a furious combat ensued. It terminated in favour of Constantius, but the victory was purchased by the loss of his bravest troops; a loss which the exhausted state of the population could not adequately supply. Next summer Constantius gained possession of Italy; and Maxentius having fled to Gaul, sustained there another defeat, and seeing further resistance in vain, put an end to his own life.

A.D. 353.

Constantius was not long permitted to enjoy his triumph in tranquillity. His cousin Gallus, whom he had created Cæsar, instigated by the ambitious Constantina, and being himself of a morose and haughty disposition, caused so much dissatisfaction in the provinces of the East, that Constantius was obliged first to recall him, and soon afterwards to put him to death. Of the race of Constantine the Great, there now remained only Julian, the cousin of the present emperor; and he escaped the fate of his brother Gallus, partly in consequence of the intercession of the empress Eusebia, partly because he had hitherto preferred a scholar's life to the dangerous eminence of military fame. He was permitted to prosecute his studies among the philosophers of Athens, from whom he imbibed that love of the mythology of ancient Greece, which led to his subsequent apostacy from Christianity.

Death of Constantius. A.D. 361.

Having thus once more arranged the affairs of the empire, Constantine paid a visit to Rome, where he was received with demonstrations of the most flattering character. But he was again called away, in consequence of the Germanic tribes assailing the western, and the Persians the eastern provinces of the empire. He sent Julian to command the armies in Gaul, and to oppose the Germans, while he himself endeavoured to maintain the eastern provinces. In his campaigns he obtained but little success; and was even compelled to abandon the siege of Bezade, which the Persians had taken. Mean while, Julian was distinguishing himself in a very remarkable manner in Gaul. Instead of a mere scholar, ignorant of every thing but the jargon of the sophists, as Constantius had thought him, he appeared at once, when in command of the army, an intrepid soldier, and a consummate general. The Franks he completely overthrew in several engagements, gained by his personal courage and his skilful conduct, even though the generals had secret orders rather to thwart than second his efforts. Having repelled the Germanic tribes, he crossed the Rhine, plunged through the morasses, penetrated the forests, and traversed the plains of Germany, spreading havoc and dismay among these ancient enemies of the empire. Constantius, envious of his renown, and jealous of his rising power, demanded from him the best legions of his army, on the pretext that their services were required in the Persian war. The legions refused to obey, and proclaimed Julian emperor. Both parties prepared for a war, to decide their pretensions to the imperial diadem; but while Constantius was exerting himself to the utmost, and while his mind was filled with rage and apprehension, he was seized with a fatal illness, and left the throne to his rival without bloodshed.

Julian the Apostate.

The high reputation of Julian, which had preceded him, procured for him a triumphant reception at Constantinople. Immediately on his arrival, he began a rigorous reform in the whole administration; banished the corrupt and servile ministers of his predecessor; dismissed those whose sole employment had been to gratify the sensual and luxurious habits of the court; appointed men of talent and activity to administer the affairs of the empire; and revived in Constantinople some of the forms of the ancient Roman constitution, particularly the senate and the consular title. But along with these reforms, he had planned a change of a much more extensive nature, nothing less than the subversion of Christianity, and the establishment of a somewhat reformed paganism in its stead. Trained as he was, in the philosophic lore of Greece, he imagined that he saw the deep mysteries of a true natural religion concealed beneath the fables of the heathen mythology; and though he did not imagine the popular mind capable of understanding the deeper meaning, he purposed to remove some of the grossest parts of the external mythic rites, give these, so reformed, to the people, and retain the secret mysteries for the learned. All this, he was well aware, could not be accomplished at once. But he adopted the most subtle methods to promote his ulterior designs. He revoked all the edicts against idolatry; discouraged Christianity, by removing Christians from all places of public honour and influence, and prohibiting them from teaching in the public schools, with the evident design of preventing them from being taught, that they might sink into insignificance.

Attempt to rebuild Jerusalem.

His attempt to rebuild the temple of Jerusalem was one of the most remarkable of his systematic endeavours to overthrow Christianity. He was sufficiently acquainted with the scriptures to know, that the final desolation of Jerusalem and dispersion of the Jews had been predicted, and was a standing miracle testifying to the truth of Christianity. This he endeavoured to refute, and turn against the cause, by rebuilding the temple in more than its original splendour, and restoring the Jews to their long-lost capital. But in this daring attempt he was signally defeated. If we may credit the testimony of contemporaneous historians, the workmen were driven from the attempt by thunders, whirlwinds, and flames bursting from the foundations which they were vainly endeavouring to lay, till terrified by these supernatural events, they were compelled to abandon the enterprize.

Persian war.

From these fruitless endeavours for the subversion of Christianity, Julian was called to take the field against the Persians, who had renewed their aggressions. Though peculiarly desirous of literary and philosophic fame, Julian was by no means destitute of military ambition. He returned a very haughty answer to the Persian ambassadors who had come to treat with him; and set out at the head of a powerful army of skilful veterans, determined to humble the pride and the power of the Persian monarch. For some time his expedition was one continued series of brilliant achievements, till bearing down all opposition, he reached the walls of Ctesiphon. But there he found himself too far from his resources to be able to continue his operations in the siege of a place which promised no speedy conquest. To advance was impossible, to retreat highly dangerous, to remain destruction. Reluctantly he commenced a disastrous retreat, through sandy deserts, oppressed with intolerable heat, deficient in provisions for his troops, and surrounded by clouds of swift Arabian cavalry. Several sharp encounters took place, in which the Roman forces gained the advantage whenever the enemy came to close combat, but suffered dreadfully from the light skirmishing warfare which they generally waged. At length a Persian arrow pierced the unguarded breast of Julian, inflicting a wound of which he died in a few hours, after an active reign of about twenty months. A. D. 363.

Jovian.

The distressed army could not be without a leader; and after a short consultation Jovian, the *first of the domestics*, a title which conferred senatorial dignity, and a rank equal to that of the military *duces*, was proclaimed emperor; and after some severe conflicts with the Persians, was obliged to conclude a treaty neither advantageous nor honourable to the empire, except that it was necessary for the preservation of the wreck of the army. Returning to his own dominions, he immediately revoked all the decrees issued by Julian against Christianity, and in favour of paganism, thus restoring the former to the supremacy which it had enjoyed since the time of Constantine. Before he reached Constantinople, to which he was directing his course, Jovian was found dead in his bed, having been suffocated, as was supposed, by charcoal. A. D. 364.

Valentinian.

After a period of ten days spent in consultation and debate, Valentinian was chosen by the imperial ministers and generals, and the army cordially ratified the choice. Soon after his elevation, Valentinian raised his brother Valens to the dignity of Augustus, and divided with him the empire, giving to Valens the eastern territories, and retaining to himself Illyricum, Italy, Gaul, Spain, Britain, and Africa. Thus were the Roman dominions once more divided into the eastern and western empires; and from the time of Valentinian, they were never again thoroughly united. Valentinian established his court, not at Rome, but at Milan, being nearer the centre of his dominions; and he was almost immediately engaged in hostilities with the restless and warlike tribes of the Germanic race. He made the most energetic efforts to drive back these invaders, and to maintain the extent of the empire undiminished; a task every year more and more difficult, from the increasing torrent of invaders, and the sinking strength of the exhausted empire. Not only were the German tribes in motion, pressing into Gaul, but the tribes bordering on the Baltic were beginning those piratical depredations which made them so long the terror of the adjacent maritime countries. In Britain the Scots and Picts were overpowering the Roman province, so that in every quarter of the western empire, nothing was to be seen but the march and countermarch of contending armies. Theodosius, the Roman general in Britain, succeeded in defending that province from its assailants, and thus gained the friendship of the emperor. To give the appearance of greater stability to his throne, Valentinian raised his son Gratian to the rank of Cæsar, and caused him to be received by the army as his successor.

In the mean time a dangerous war arose in Africa, where the avarice and cruelty of Count Romanus, the military governor, had excited general dissatisfaction. The complaints of the injured Africans having been guilefully misrepresented to Valentinian, he punished the complainers. Despairing of redress, the people revolted, and chose Firmus, the son of a man of great wealth and influence in the country, for their leader. Romanus was quite unable to suppress this rebellion; but Valentinian despatched the warlike Theodosius with a strong force, to reduce them to subjection. Immediately on his arrival, the aspect of affairs was changed. Firmus was defeated with great loss, and fled to a friendly tribe in the interior; but fearing to be betrayed, he committed suicide, to avoid falling into the hands of the conqueror. Valentinian himself had in the mean time been engaged in conducting an expedition against the Quadi, and other nations on the Danube, in which he was successful; but died suddenly of apoplexy, near the modern city of Guntz in Hungary. A.D. 37

Gratian.

Gratian, the eldest son of Valentinian, succeeded his father in the western empire, and immediately associated with himself his brother Valentinian II., at that time only a youth of five years old, assigning to him Italy and Illyricum. Among the first and the worst acts of his reign, was the sanctioning the execution of Theodosius, whose brave and skilful conduct had preserved Britain, and recovered Africa. To this he was instigated by the calumnious insinuations of envious courtiers, who both hated and feared the rising merit of that gallant warrior. The reign of Valentinian, though filled with wars, had been so prosperous that it had secured for his sons a period of comparative tranquillity, more suited to their youth and inexperience. But the eastern empire had neither enjoyed equal prosperity, nor was enjoying the prospect of equal tranquillity.

Almost at the very commencement of his reign, Valens, the eastern emperor, was compelled to make preparations for a new Persian war; and, in the midst of these preparations, was alarmed by a dangerous rebellion. This was raised by Procopius, a distant relation of Julian, whose pretensions to the throne were founded partly on his consanguinity to the former emperor, and partly on a rumour that Julian had himself secretly invested him with the purple. Procopius was at first successful; but his haughty and cruel temper disgusting his own supporters, he was deserted by them, taken by the emperor, and put to death. The Persian war proceeded favourably, Sapor receiving a severe defeat, which was soon followed by a peace. But a more important event occurred, formidable not only to Valens, but also to the whole of the western world. This was the appearance of a new moving nation of barbarians, called Huns. Respecting the origin of this people, there are va-

The Hun

rious opinions, of which the most commonly received is that which represents them as sprung from the great family of the Mongolian Tartars, and in some way connected with those tribes called by the Chinese, Hioung-Nou. But there was also among them a manifest mixture of various nomad tribes, of which the predominant were probably the Finnish. It would indeed be absurd to imagine that a mighty migration of nomad tribes, sweeping onwards from the wilds of Mongolia to the Tanais (Don) and the Palus Mæotis (Sea of Azov), could be other than a mingled mass of all the various tribes whom they had conquered and absorbed in their tide-like course. Crossing the Tanais, the Huns drove before them the nations north of the Danube; and these uprooted nations in their turn threw themselves headlong upon the Roman provinces, both impelled and supported by the countless hordes that continued to press resistlessly behind. The Goths, unable to repel these terrible barbarians, sought and obtained permission to settle in the waste lands of Thrace, which formed part of the Roman province of Mœsia. Unfortunately for both themselves and the empire, the Goths had been taught Arianism, and as a very violent hatred subsisted between the Arians and the orthodox Christians, the Goths neither were well received by the Romans, nor entertained sentiments of much friendship towards them. And not less unfortunately, the officers whom Valens appointed to superintend the new settlements of the Goths were men of the most depraved and abandoned characters, and treated them with the utmost perfidy and cruelty. At length Lupicinus, the chief of these officers, attempted at a feast to murder Fritigern and the other Gothic leaders; but the plot being prematurely discovered, the Gothic chiefs escaped, and arming their followers, massacred the greater part of the Roman troops in the province. In the mean time, the Huns advancing on their devastating career, drove the Ostrogoths before them into the territories possessed by the Visigoths; and thus mightily swelled the strength of the infuriated Goths. Uniting themselves under Fritigern, the Goths laid waste Thrace, Macedon, and Thessaly, and approached to the very walls of Constantinople.

In this state of affairs, Valens, assailed by a strong and vengeful foe, applied to Gratian, the young emperor of the west, for aid. He had been engaged in warring successfully against the Germans, and was at that time in the field; but seeing the urgent necessity of saving the eastern empire, he immediately marched to the assistance of his uncle. Before his arrival, the Gothic chief, Fritigern, thinking it lawful to use deceit against a deceitful foe, found means to draw Valens into a situation in which he was almost compelled to fight, without waiting for the arrival of succour. A decisive battle was fought near Adrianople; Valens himself was killed on the field, and nearly two-thirds of the Roman army were cut to pieces. Not even on the dreadful field of Cannae had the Romans sustained a more fatal overthrow; and the stern unconquerable spirit of the republic being no more, the fate of the eastern empire seemed to be inevitable. But what direct force might not have been able to accomplish, was effected by a rare combination of wisdom, valour, and probity. In consequence of his wars with the invaders of his own dominions, Gratian was unable to undertake the conduct of the war against the Goths; but he called to his aid Theodosius, son of that Theodosius whom he had unjustly put to death, and whose death he had bitterly repented. Him he now raised to the dignity of emperor, and gave him at once the eastern empire, with the addition of the province of Illyricum. Theodosius thus raised to the purple, speedily showed himself worthy of the high trust committed to him, that of restoring the fortunes of a falling empire. The courage of the Romans had been so much shaken by their late defeat, that Theodosius did not think it prudent to hazard a general engagement with the Goths; but, like another Fabius, he saved his own forces, harassed the enemy, taught his men that the Goths were not invincible, and gradually restored to them their courage, perfected by improved discipline and temperate caution. At length Fritigern died; and the Goths having no longer a leader capable of controlling the haughty chiefs of their ill-compacted confederacy, became disunited, and one by one submitted to the superior skill, policy, and authority of Theodosius. Great numbers of them received the pay, and were incorporated into the armies of that empire which they had so recently been on the brink of destroying, and the remainder voluntarily engaged to defend the Danube against the Huns. Thus, in about four years, the eastern empire was rescued from the most formidable danger by which it had ever been assailed, and seemed once more in a state of security.

D. 378.

eodo-

While Theodosius was thus employed, another calamity befel the western empire. The character and conduct of Gratian had defrauded the fair expectations formed of him on his accession, and exposed him to the contempt of the more warlike part of his subjects. Maximus, who held the chief command in Britain, revolted against him, passed into Gaul, and prepared to dethrone the feeble emperor. The army violated its allegiance, and Gratian having fled towards Italy, was overtaken and killed at Lyons. The death of this prince left his young brother Valentinian II. nominal emperor of the west, though the usurper Maximus assumed that title. Theodosius was obliged to conceal his resentment against the murderer of his benefactor, not being yet in a condition to quit his own dominions; and he even entered into a treaty with him, leaving him in the undisturbed possession of Gaul and Britian. But Maximus, encouraged by the success with which his rebellion had been followed, resolved to deprive Valentinian of even the nominal power which he enjoyed in Italy. Unable to defend his territories, he fled to Theodosius, and besought his aid. Theodosius having completed the pacification of his own dominions, immediately marched against the usurper, defeated him in two successive engagements, and his own troops having yielded him up, put him to death. Valentinian II. was thus restored to the throne of the western empire; a throne which his weak character did not enable him to fill and to defend.

Valentinian II.

Overthrow of paganism at Rome.

Theodosius, after his triumph over Maximus, resolved to visit Rome, and aid his imperial pupil in reforming the abuses prevalent in that city. This visit is memorable on account of the decrees published by Theodosius for the complete suppression of idolatrous worship in Rome. All sacrifices were prohibited under heavy penalties, the idols were defaced, and the temples of the gods abandoned to ruin and contempt. These decrees met but a feeble resistance, and from that time may be dated the complete and final overthrow of pagan idolatry in Rome. It would be an easy though an unpleasant task, to show how the ill-judging teachers of Christianity, in their zeal to make converts, in order to make the transition more easy to the pagan multitude, adopted many of the rites and festivals of the ancient idolatry, assigning merely to some saint what had been ascribed to some subordinate deity, and thus introduced much of the ill-disguised heathenism which forms so large a proportion of papal superstition: but this we leave to the pen of the ecclesiastical historian. Having thus completed the triumph of Christianity over paganism, Theodosius returned to the east, and employed himself in the kindred task of putting an end to the heresies of the church, establishing the predominancy of the orthodox over the Arian party.

A.D. 392.

Valentinian II. had but a short time recovered possession of the empire of the west, when he was murdered by Arbogastes, a Frank of a bold and warlike character, who had obtained a great ascendancy over him. Arbogastes did not himself assume the purple, but gave it to Eugenius, deeming it more safe to possess the power than the name of emperor. Theodosius once more prepared to avenge the murder of an emperor. He raised a powerful army, forced the passes of the Alps, encountered the army of the usurper, and inflicted on him a decisive overthrow. A.D. 394. Eugenius was killed by his own defeated troops, and Arbogastes, fearing the just resentment of the victor, died by his own hand.

The whole Roman empire might have been once more reunited under one imperial sovereign, had Theodosius been ambitious of that sole dominion. But being perfectly persuaded of the necessity of an emperor in each of the imperial cities, he assigned to his younger son Honorius the sceptre of the western empire, and associated Arcadius, the elder, with himself in that of the east. Scarcely had he completed this arrangement, when his constitution, which had always been feeble, overtasked with the exertions of this campaign and the cares of state, yielded to the shock, and he expired, to the universal regret of the empire, which beheld the splendour of the Roman name passing away with him its last great emperor. A.D. 395.

Stilicho, master-general of the army.

The Roman world now presented the miserable spectacle of two emperors of such imbecility as to be incapable of conducting the administration of public affairs, in a time of such peril and alarm as would have required the prudence of an Augustus joined to the martial skill and talents of a Cæsar. That Theodosius was not unaware of the feebleness of his two sons, may be conjectured from the fact of his assigning the care of at least the western empire to Stilicho, the master-general of the army. This able general seems to have been a Vandal by origin, but had by his courage and his great abilities raised himself to the highest military fame and station before the death of Theodosius; and to him that prudent emperor entrusted the guardianship of the empire. In the east, the crafty and avaricious Rufinus enjoyed similar influence over the feeble Arcadius, but without equal merit to sanction his possession of that power. Stilicho governed by the inherent right of commanding genius; Rufinus by the dark intrigues of a guileful and selfish nature. Stilicho seemed to regard himself as entitled to the supreme care of both empires; and Rufinus endeavoured to secure his authority in the east by persuading Arcadius to marry his daughter. He was however frustrated by the eunuch Eutropius, a person still more crafty than himself, who induced the young emperor to share his throne with the beautiful and accomplished Eudoxia. In a short time afterwards, Rufinus was killed by the leader of a body of Gothic troops in the confidence of Stilicho, who did not however obtain the ascendancy over Arcadius, being supplanted by the intrigues of Eutropius.

In the mean while, a dangerous war broke out in Africa, under the command of Gildo, brother of Firmus, who had been the leader of the last revolt. To suppress this insurrection, Stilicho sent Mascezel, the brother and deadly foe of Gildo. The Romans obtained the victory almost without bloodshed; and Gildo terminated his days by his own act, in a dungeon into which he had been cast. Mascezel did not long enjoy his victory, having been drowned either by accident, or, as some allege, by the contrivance of Stilicho.

War with the Goths.

But the fiercest storm that had ever assailed the empire was now ready to burst upon it in its hour of weakness. The Goths had yielded to the arms, and especially to the policy of Theodosius. After the death of Fritigern and of Athanric, they had been for some time without a leader able to combine them into one body. A leader of equal craft and courage now appeared in the famous Alaric, who having succeeded in establishing his authority over his countrymen, only waited for a fair pretext, and a favourable opportunity to put in practice a scheme of greater magnitude and daring than had entered into the mind of any of Rome's assailants since the time of Hannibal. The corrupt and avaricious ministers of Arcadius soon afforded him a pretext sufficiently plausible, by withholding the subsidy paid to the Goths since the agreement with Theodosius. Not deeming the lands of Thrace worth his while, Alaric led his forces into Greece, passed the straits of Thermopylæ without opposition, devastated its fairest lands, and plundered Athens, Corinth, Argos, and Sparta. A.D. 39 The unwarlike emperor of the east and his effeminate courtiers did not dare to meet the warlike barbarian; and Stilicho marched against them to rescue Greece from her rude plunderers. The great military genius of Stilicho was soon apparent in the advantage he obtained over the Goths, whom he at length succeeded in driving into a straitened position in Elis, whence it seemed impossible for them to escape. Taking advantage of the relaxation which security had produced in his antagonists, Alaric forced the lines of circumvallation, crossed the narrow strait at the mouth of the gulph of Lepanto, and resumed his ravages in Epirus. Before Stilicho could again reach his enemy, he received information that the emperor of the east had concluded a peace with Alaric, and had even made him master-general of Illyricum.

Alaric the Goth.

Stilicho yielded to the unwise policy of Arcadius, and returned to Italy; but was very speedily recalled to march against his baffled but unvanquished foe. Resolved if possible to make himself master of the western empire, Alaric crossed the Julian Alps, and marched rapidly towards Milan, where Honorius held his court. Stilicho hastened to recruit his army and to defend the empire; but before his preparations were complete, the swift march of Alaric compelled Honorius to fly from Milan. In his flight he was almost surrounded by the Goths, and took refuge in Asta, where he was immediately besieged. Stilicho hastened to the rescue of the emperor; and gained a great, but not decisive victory over Alaric at Pollentia. Rallying the remains of his shattered army, Alaric quitted the scene of his defeat, and marched furiously to Rome, determined to wreak his vengeance on that proud city, or to perish at its gates. But Stilicho at the head of a chosen body of his army hastened with scarcely less swiftness to the relief of the threatened capital, and arrived in time to protect it from the rage of Alaric. He did not however deem it safe to force his antagonist to a battle, dreading perhaps the almost invincible energies of a brave enemy's resolute despair; and thought it preferable to purchase his retreat, though at the expense of a very large sum of money.

Though frustrated in this attempt, Alaric did not relinquish his intention of making himself master of the western empire. He retreated towards Gaul, and attempted to seize Verona, intending to retain it as an open door by which to invade Italy when he should be supported by the strength of Gaul. Stilicho being apprised of his intention, followed, beset, and brought him to an engagement at Verona, and inflicted on him a second great overthrow, but could not prevent his escape, with a spirit undismayed, and a resolution only confirmed of implacable hostility to Rome. After this deliverance, Honorius went to Rome to enjoy the honours of a triumph; but this timid prince was not satisfied with a residence in any city which was exposed to the dangers of invasion. He therefore withdrew to Ravenna, a small fortified town on the banks of one of the mouths of the Po, deemed inpregnable from its situation; and here he determined to fix his imperial residence.

The Vandals.

Another enemy now appeared to summon forth afresh the energies of the brave and indefatigable Stilicho. This was another combined host of roving nations, chiefly Vandals, Alani, Suevi, and Burgundians, under the command of Radagaisus. On their march a large body of this moving mass separated, and entered Gaul; while the rest under their chief entered Italy and laid siege to Florence.

Again did Stilicho by his superior tactics save his own army, and overthrow that of the enemy, enclosing them within such entrenched lines as they could not force, and reducing them to such distress that they were compelled to surrender at discretion. Radagaisus was put to death; and the greater part of his army sold as slaves. Of this fresh tide of migrating barbarians, the portion which turned towards Gaul was more successful. They devastated the whole of that country, crossed the Pyrenees, and formed a settlement in Andalusia.

D. 408.

Stilicho was now suspected of a secret intercourse with Alaric, whom he had several times defeated, but always suffered to escape. A correspondence certainly existed between them; and Stilicho even attempted to persuade Honorius to frame a treaty with Alaric, and to give him the province of Illyricum. In the midst of these political intrigues, Olympius found means to gain the confidence of Honorius, and procured the murder of the brave and able Stilicho, the deliverer of Italy. As if to prove the infatuation of guilt, Olympius next procured the murder of the wives and children of the barbarians throughout Italy, which, instead of weakening their power, strengthened it by the just resentment which so atrocious a deed awoke in their fierce, yet human bosoms. They immediately invited Alaric to head them in avenging the slaughter of their families; and thus about thirty thousand brave and disciplined men were by one bloody and treacherous deed converted from auxiliaries into the most implacable foes, while the death of Stilicho encouraged Alaric to invade a country no longer defended by that renowned warrior, before whom his own martial genius had stood rebuked.

ome be-
ged.
D. 408.

itu-
s.
D. 409.

Delighted to see his great scheme so nearly within his reach, Alaric once more entered Italy and marched directly against Rome.[1] By a skilful arrangement of his forces, he cut off all supplies, and the devoted city was soon subjected to the aggravated horrors of war, famine, and pestilence. Safe in his retreat at Ravenna, the emperor made no effort to save his capital; and after suffering the most dreadful miseries, the senate purchased a cessation of hostilities and the retreat of the besieging army, by the payment of an enormous ransom. Alaric withdrew to Tuscany, and waited the ratification of this treaty by the emperor, being unwilling to come to extremities, under the hope of yet obtaining such an alliance with Honorius as should raise him to the command of the armies of the whole western empire, which he might govern in the name of the emperor, as Stilicho had done. Honorius refused to ratify the treaty; and Alaric once more invested Rome. In this second siege Alaric took measures to secure a more speedy triumph. He seized upon the harbour of Ostia, which contained the granaries for supplying the city; and the Romans were compelled at once to capitulate. Still the conqueror modified his triumph, contenting himself with raising Attalus, præfect of the city, to the empire. Notwithstanding this virtual dethronement of Honorius, Alaric continued to negotiate with that feeble monarch, whose name bore a higher dignity than that of Attalus. Having again failed to obtain his wishes, he deposed Attalus, and marched against Rome, resolved no longer to control the strong impulse which had long urged him to the sack of Rome. The barbarian army once more approached the walls. During the darkness of night the Gothic slaves within the city seized one of the gates, and threw it open to their countrymen, setting fire to some adjacent houses to light their entrance and to begin the work of devastation, spoil, and carnage. For six successive days of horror the Goths were allowed to glut their furious appetites in the sack of the prostrate queen of the world, restrained only by their own respect for the churches, where numbers of the trembling inhabitants found a sanctuary.

Taking of Rome by Alaric. A.D. 410.

It was not the intention of Alaric to destroy Rome, but rather to make himself its sovereign. After he had attempted this by policy and intrigue, he accomplished it by force. His ambition now expanded with his success; and he resolved to subjugate all Italy, pass into Sicily and add it to his conquest, thence into Africa, and annex it to his dominions, and thus to make himself the sovereign of the whole western empire. But while on his march through southern Italy for the accomplishment of these vast designs, he was suddenly smitten with a mortal malady, and died near Consentia. Before his death he gave orders that he should be interred in the channel of the small river Busentinus. The river was turned aside by the labour of captives, the royal sepulchre dug in the vacant bed, the body, richly adorned with the spoils and trophies of Rome, was deposited, the waters were restored to their channel, and the prisoners who had executed the work were murdered, that it might not be known where he lay, and that the hand of man might never insult the ashes, and the foot of man never tread upon the grave, of Alaric the Goth, the conqueror of Rome.

Death of Alaric. A.D. 410.

After the death of Alaric, the command of the Gothic army devolved upon his brother Adolph, who, though not destitute of talents, possessed neither the fierce passions nor the high ambition of Alaric. He concluded a peace with Honorius, consenting to quit Italy upon condition of the princess Placidia being given to him in marriage. This being done, he acted as a Roman general, led his forces into Gaul, and reconquered that country for the emperor. Thence he passed into Spain, and began a fierce war against the other barbarian nations by whom that country had been invaded; but was murdered in the midst of his victorious career. His successor Wallia continued the war with equal vigour and success, till he subdued nearly all Spain, and founded the Gothic monarchy. Placidia was sent back to her brother Honorius, on the remonstrances of the emperor's victorious general Constantius, at the head of a powerful army; and she was afterwards given in marriage to the brave leader by whom she was thus recovered.

A.D. 423.

Constantius did not long enjoy his dignity; and upon his death Placidia sought a retreat in the court of Theodosius, taking with her to Constantinople her two infant children Valentinian and Honoria. Within a few months after this event, which renewed the intercourse between the imperial families of the East and of the West, the emperor Honorius died of dropsy. The throne was immediately seized by John, the Primicerius, or principal secretary of the late emperor. Thedosius II. who had succeeded his father Arcadius in the empire of the East, prepared to place his cousin on the throne of Rome. The eastern army took Aquileia, and obtaining possession of Ravenna, where the usurper then was, put him to death, and secured the Italian crown. After some little delay, the son of Honorius, an infant only six years old, was raised to the throne, by the name and title of Valentinian III., emperor of the West; the administration of affairs being conducted by his mother Placidia. It is worthy of remark, that both divisions of the Roman empire

Valentinian III.

---

[1] The state of Rome at that eventful period cannot be better described than in the language of Gibbon. "It had attracted the vices of the universe, and the manners of the most opposite nations. The intemperance of the Gauls, the cunning and levity of the Greeks, the savage obstinacy of the Egyptians and Jews, the servile temper of the Asiatics, and the dissolute, effeminate prostitution of the Syrians, were mingled in the various multitude; which, under the proud and false denomination of Romans, presumed to despise their fellow-subjects, and even their sovereigns, who dwelt beyond the precincts of the Eternal City."

were at this juncture governed by females; the East by Pulcheria, in the name of her brother Theodosius II., and the West by Placidia, in the name of her son Valentinian III.

The two rival generals, Bonifacius and Ætius.

While Rome was assailed on all sides by fierce barbarian nations, it was extremely necessary that either the sceptre should be swayed by a warlike monarch, or that men of military talents should occupy the chief places of trust and influence. The western empire was governed by a woman in the name of an infant; but there were two men at the head of its armies equal to the burden of its support and defence, had they not been rendered foes by jealousy and intrigue. These were Bonifacius in Africa, and Ætius in Italy, both men of great abilities, but the latter envious and designing. In order to ruin his less cunning rival, Ætius wrote to Bonifacius to inform him that the empress Placidia wished his death, and meant to recall him from Africa for that purpose; and at the same time he persuaded Placidia that Bonifacius meant to rebel, and advised her to recall him for the purpose of proving his obedience. When the order reached Bonifacius, it confirmed the fallacious statement of Ætius, and he refused to return; this refusal convinced Placidia of his traitorous design, and she caused him to be proclaimed a traitor, thus driving him into rebellion. Bonifacius was well aware that he could not hope to contend successfully against the veteran troops of Rome, led by Ætius; and he therefore had recourse to the aid of Genseric, king of the Vandals, at that time settled in Spain. This ambitious and daring barbarian immediately crossed the straits of Gibraltar, entered Africa, and commenced a course of dreadful devastation. Bonifacius learned, when too late, how he had been deceived; and he then attempted, but in vain, to check the progress of the savage invaders. He was defeated, the cities that opposed the Vandals were taken, and Africa was wrested from the power of Rome, and completely overrun by the barbarians.

Genseric the Vandal.

As the innocence of Bonifacius had been proved by the deceitful letters of Ætius, he was received on his return to Italy, with marks of favour by the empress. This roused the utmost wrath of Ætius, and a sort of civil war arose between the two rivals, in which Bonifacius was slain; but the empress, who was now thoroughly acquainted with the treachery of Ætius, proclaimed him a traitor, and he fled to the Huns, with whom he had maintained a secret alliance. In a short time afterwards he returned to Italy, requesting re-admission to the councils of the empire, and supported in his requests by an army of sixty thousand barbarians. Placidia was obliged to accept his proffered assistance, to raise him to the dignity of a patrician, and to the command of the imperial armies, and consequently to the government of the empire.

No sooner had Ætius secured this object of his ambition, than he resolved to recover the lost province of Africa; and for this purpose, availing himself of the indignation which the cruel and barbarous treatment of his sister by Genseric had excited in the mind of Theodoric, king of the Visigoths, he endeavoured to frame such a treaty with that monarch as should induce him to aid the Romans against the common foe. This politic design was however discovered by the crafty barbarian, Genseric, who defeated it by inducing the terrible Attila, king of the Huns, to invade the empire. For some time this powerful barbarian had ruled with despotic sway over the whole nation of the Huns, and kept both the courts of Rome and Constantinople in terror, levying a tribute from each, as the price of his temporary forbearance. The death of Theodosius II., and the accession of Marcian, the nominal husband of Pulcheria, infused a more determined spirit into the councils of the eastern empire; and the fury of Attila might have been directed against it, rather than the west, had it not been for the intrigues of Genseric, who induced the fierce king of the Huns to bend his course westward, and pour the torrent of his almost countless multitudes through Germany into Gaul. The haughty barbarian had also another pretext. The princess Honoria, daughter of Valentinian, is said to have offered him her hand; and Attila, availing himself of the proffer, demanded her in marriage, together with a portion of the empire as her dowry, and advanced at the head of an immense army to enforce his demands. All opposition was in vain, till he reached Orleans in Gaul, which sustained a siege for some time, in the hope of succour from the confiderate forces of Ætius and Theodoric. At length the allied army appeared, when the Huns were actually forcing their way into the town, and Attila called them back, and retired into the plains around Chalons, (*in campis Catalaunicis*,) to obtain space for the evolutions of his mighty army. After a battle, fierce, varied, obstinate, and bloody, in which the nations from the Wolga to the Atlantic were engaged, Attila was beaten back to his camp, and the field, covered with the dead bodies of 162,000 slain, remained in the possession of Ætius, Theodoric having fallen in the battle. Attila retreated into Germany, still too formidable to be more than harassed on his march.

Attila the Hun.

Battle of Chalons A.D. 45

During the following spring, he renewed his attempt, but now directed his course into Italy itself, and laid siege to Aquileia, which he took after a protracted and desperate resistance. Ætius could not induce the Visigoths to render him any assistance, and his own forces were unable to meet the vast armies of the Huns; yet he continued to keep the field, and to impede the progress of the dreadful invader. His march was now to be directed against Rome, when he was prevented, partly by the offers of an embassy sent to him from the timid Valentinian, and partly in consequence of a superstitious feeling of apprehension for his own life, both friends and foes reminding him that Alaric had not long survived the taking of Rome. He consented to accept a large ransom and the princess Honoria, threatening to return filled with implacable vengeance, should the stipulations of the treaty not be fulfilled. Soon after his return to his almost imperial village, he fell a victim to intemperance, and died by the bursting of a blood-vessel, on the night after a feast held in honour of his own nuptial engagement with the fair Ildico. Thus perished the terrible Attila, a man of matchless energy of character, a barbarian surpassing all in the barbaric pride and cruelty in which he delighted; who directed his ambassadors to say to the two emperors of Constantinople and Rome, "Attila, *my* lord, and *thy* lord, commands thee to provide a palace for his immediate reception;" who delighted in uttering the ferocious boast, that the grass never more grew on the spot once trodden by his horse; and who actually adopted the appellation given to him by a trembling enemy, *Attila, the scourge of God.*

Death of Attila. A.D. 45

Upon the death of Attila, the kingdom of the Huns was torn to pieces among his followers; and Rome might have enjoyed safety, had not the jealousy and ingratitude of Valentinian led him to murder with his own hand the brave Ætius, the only person capable of protecting the empire. Not long afterwards, Valentinian himself was killed by the patrician Maximus, whose wife the weak and dissolute tyrant had violated, and who ascended the throne thus rendered vacant.

A.D. 45

Maximus

Soon after his assumption of the imperial dignity, the wife of Maximus died; and wishing to obtain a sanction for his elevation, he married Eudoxia, the widow of Valentinian, and sister of the eastern emperor. In some moment of strange imprudence, he told the empress that he had caused the murder of her first husband Valentinian; and to revenge the deed, she privately invited Genseric, the Vandal conqueror of Africa, to invade Italy, and dethrone the usurper. Genseric had built and equipped a powerful fleet, which rendered him master of the sea, and put it in his

ome
ken by
enseric.
.D. 455.

power to devastate the maritime countries around the Mediterranean. His answer to Eudoxia was the speedy appearance of a Vandal fleet in the Tiber. The terror of the Roman citizens vented itself on Maximus, who was put to death in a tumult of popular indignation; but Genseric landed and took possession of the city, which immediately became a scene of horrors, surpassing those caused by the storm and pillage of Alaric and his Goths. For the space of fourteen days and nights did the savage Vandals indulge their rapacious appetite for plunder, by seizing upon all the public and private wealth which had escaped the Goths, or been accumulated since their departure. Eudoxia herself was despoiled of her jewels, and compelled, along with her two daughters, to embark on board the vessels of the barbarous plunderer. Great numbers of the Roman citizens were carried away to Africa as slaves, the only mitigation of their sufferings being what was purchased from the Vandals by Deogratias, bishop of Carthage.

vitus.

Before the death of Maximus, he had appointed a noble Gaul, named Avitus, to the command of the troops in that country. When the death of Maximus left the empire without a sovereign, the army proclaimed Avitus; and the friendship of Theodoric, the king of the Visigoths, induced him the more readily to accept the dangerous honour. But he enjoyed his elevation a short time. Ricimer, commander of the barbarian mercenaries in the armies of the empire, descended of the royal race of the Visigoths by the mother's side, and of the nation of the Suevi by the father's, having defeated the Vandals in a naval action, and been hailed "deliverer of Italy," found himself strong enough on his return, to depose Avitus, who was allowed to become bishop of Placentia, but he did not live to enjoy his ecclesiastical preferment.

D. 456.

ajorianus

For a short time Ricimer continued to govern the empire without the appointment of an imperial ruler; but at length he raised to that position Majorianus, a man of courage and merit, who had been trained under the care of Ætius, and was equally skilled in the arts of the field and the cabinet. His first attempt was to check the growing degeneracy of Rome, by amending the laws, making a new distribution and arrangement of the taxes, restoring and reforming the magistracies, preventing the destruction of public edifices, and especially by such a vigorous resumption of the ancient discipline of the armies, as should render them able to meet their enemies with their former certainty of victory. He levied troops, repelled an invasion of the Vandals, constructed a fleet, and prepared to carry the war into Africa, for the recovery of that province, which had long been the very granary of Rome. But it was not the policy of Ricimer to allow a truly able and heroic monarch to occupy the imperial throne, lest he might rouse the Romans from their deep degeneracy. He fomented a sedition in the army, in consequence of which Majorianus was compelled to abdicate; and five days after his abdication he died, as was reported, of a dysentery, more probably of treachery. In him perished the hopes and the prospects of Rome, of ever again obtaining deliverance from the degradation of barbarian sway.

D. 461.

ius
erus.

, At the command of Ricimer, the senate named as emperor Libius Severus, an obsequious dependant of the imperious barbarian, who continued to hold the nominal dignity of emperor for a period of six years, during which the whole power was so completely retained by Ricimer, that the name of Severus is scarcely ever mentioned by the historians of the time. At length the growing power of the Vandals in Africa, and their incessant depredations on the coast of Italy, compelled Ricimer, who had no naval force to oppose them, to apply for aid to the emperor of the east, and to offer him the appointment of a western emperor as an inducement. The opportune death of Severus enabled Ricimer to make this offer freely, if indeed he had not caused that death; and Leo, the eastern sovereign, nominated Anthemius to that ill-omened station. A combined armament was prepared by the Constantinopolitan and Roman emperors, and sent against the Vandals; but the superior conduct of Genseric prevailed, and the confederate force was almost totally destroyed. Bereft of his eastern support, Anthemius was unable to maintain himself against the powerful and ambitious Ricimer, who first withdrew from Rome to Milan, and there held a separate and independent court, and then marched toward Rome in open rebellion against the emperor. For some months Anthemius defended the city; but at length it was carried by storm, and the unhappy emperor being dragged from concealment, was murdered by the command of Ricimer.

Anthemius
A.D. 467.

A.D. 472.

Anycius
Olybrius.
A.D. 472.

Anycius Olybrius, the son-in-law of Valentinian III. was next placed on the throne, by this daring and successful setter-up and puller-down of emperors. Within about a month after this exploit, Ricimer himself followed his imperial victims to the grave, being cut off by a painful disease; and before other two months had elapsed, Olybrius died a natural though an early death.

Julius
Nepos.

Even ambition could not rouse the sluggish court of the east to activity, although the death of Ricimer rendered it probable that the nomination of a new emperor would meet with little opposition. At length Leo named to that dignity Julius Nepos, who had married a relation of the empress, and had previously held the government of Dalmatia. In the meantime, Gundobald, the Burgundian prince, and nephew of Ricimer, had raised to the throne an obscure soldier named Glycerius; but upon the approach of Nepos, supported by the troops of Leo, Glycerius fled, the Burgundians not thinking proper to engage in a war for his defence, and he is said to have consulted his safety in the new character of bishop of Salona.

Glycerius.
A.D. 474.

Nepos enjoyed the sovereignty but a very short time. The barbarian confederates, or auxiliary troops, broke out into a violent sedition, and marched, under the command of their general, Orestes, a native of Pannonia, of high descent, against Ravenna, where Nepos had his court. Instead of confiding in the strength of the fortress, and hazarding the contest, Nepos fled across the Adriatic to his former Dalmatian province, and lived in obscurity till he was murdered by the instigation of his former rival Glycerius.

A.D. 475.

Romulus
Augustulus

Orestes did not himself think proper to assume the purple, but gave it to his son Romulus, or, as corrupted by the half-barbarian half-Greek pronunciation of Pannonia, Momyllus, to whom, as raised to the imperial dignity, was also given the name of Augustus, afterwards changed into Augustulus; in whom thus met, by a strange combination, the names of the founders of the city, and of the empire. But Orestes soon found that it was easier to usurp than to retain supreme power. The barbarian mercenaries, headed by Odoacer, a bold and enterprizing chief of the Heruli, demanded a partition of the lands of Italy among them, to at least a third; and upon the refusal of Orestes, they flew to arms, mustering from all quarters, besieged and took Pavia into which Orestes had thrown himself, and put him to death. Odoacer next directed his march to Rome, and was met by Augustulus, who voluntarily abandoned the insignia of imperial sway, and appealed to the clemency of the conqueror. His life was spared, and he was allowed to retire to the villa which had belonged to Lucullus, where he was allowed a sum of money for his support. Odoacer retaining the entire sovereignty, contented himself with the title of king, and thus put an end to the Roman Empire of the West, in the 1229th year from the foundation of Rome.

Odoacer,
king of the
Heruli.

A.D. 476.

Statistics of Rome.

Though this was the actual termination of the Roman Empire, yet it ought to be added, that Odoacer never assumed the purple and diadem, or the title of king of Italy, being satisfied with the regal title alone, without any local application; and that after a comparatively peaceful, prosperous, and prudent reign of fourteen years, his fortunes sunk before the superior genius of Theodoric, the king of the Ostrogoths, a prince alike capable of founding or reconstructing a monarchy, under whose sway all vestiges of the imperial government were swept away, or remodelled, and Italy was formed into a kingdom.

Theodoric the Ostrogoth.

There is no portion of profane history more pregnant with important instruction, than that which relates to the rise, the growth, the fluctuations, and the fall of Rome. It equally demands the studious attention of the scholar, the statesman, the philosopher, and the Christian. In its literature, the scholar will find treasures second only to those of Greece; in its political struggles and changes, the statesman will find much to guide him in his endeavours to mould the constitution of his own country; in its peculiar mental aspect and character, the philosopher will find a full development of one of the most vigorous and striking phases of mind that have ever been displayed in the history of humanity; and in its resistance to the pure and simple truths of the gospel, the Christian will be led humbly to ponder on the deep depravity of man, and the danger of rejecting that system of religion which can alone elevate the character of individuals, and promote the security and happiness of communities. To point out the full application of these views would require a dissertation far beyond our limits; and we must therefore leave the intelligent and inquisitive reader to trace them for himself, well assured that the labour will amply prove its own reward.

(B. O.)

STATISTICS OF ROME.

Having thus related at length the rise and progress, decline and fall, of the empire of Rome, we now proceed to give a topographical and statistical description of that famous city.

Rome, by the shortest route, Brighton, Dieppe, Paris, Geneva, Simplon, Milan, Bologna, Florence, and Sienna, s about 1169 English miles distant from London.

Hills of Rome

The hills of Rome are chiefly composed of volcanic granular tufa, but the greater part of the Capitoline is lithoid tufa, which resembles the peperine stone of Albano, and the same material is found in some parts of the Cælian and Aventine hills. The valleys among the hills are chiefly of siliceous-calcareous sand, but argillaceous substances are very prevalent in the soil of Rome.[1] The height, in English feet, of the principal hills above the sea, is as follows: Capitol, at west angle of Tarpeian rock, 151; at north end, 160; Palatine, 170; Aventine, 148; Cælian, 146; Esquiline, 180; Quirinal, at Pope's palace, 150; Pincian, 206.

Modern Rome occupies a triangular space, each side of which is nearly two miles long. The ground upon which it is built covers about 1000 acres, or one mile and a half square; its walls form a circuit of fifteen miles, and embrace an area of 3000 acres. The greatest part of the population of Rome is now comprised within the limits of the Campus Martius. Three of the seven hills are covered with buildings, but are only thinly inhabited; the Transtiberine district, including the Borgo, contains the rest of the inhabitants. The ancient city, however, was more than treble the size of the modern, for it had very extensive suburbs beyond the walls. The greater portion of the city stands extremely low, being only from forty to fifty feet above the sea, though sixteen miles distant from it. The Tiber, where it enters the city, is only about twenty feet above the level of the sea.

According to the unanimous opinion of all ancient writers, Rome was originally confined to the Palatine hill,[2] and after the union of the Romans with the Sabines, the latter, with their king Tatius, had their abode on the Capitoline. After the death of Romulus, a temple to his honour, under the name of Quirinus, was erected by Numa on the Quirinal hill, to which it gave the name.[3]

The Cælian hill was added by Tullus Hostilius, who had his own dwelling there, and appropriated part of the mount for the residence of the conquered Albans.[4] The Aventine mount was annexed to Rome by Ancus Martius, the fourth king, who gave it for the accommodation of the Latins after his conquest of their country.[5] He also surrounded mount Janiculum with a wall, and erected upon it a fort, lest this advantageous post should fall into the possession of an enemy. He likewise connected it with the city, by throwing across the Tiber the famous bridge called the *Pons Sublicius.* When the waters of the river are not above their usual level, the traveller may still see the foundations of this bridge, the scene of the heroic exploit of Horatius Cocles.[6] The city, which now contained four hills, the Palatine, the Capitol, the Cælian, and the Aventine, was enclosed with a stone wall by Tarquinius Priscus; and his successor Servius Tullius having added the Quirinal, Viminal, and Esquiline hills, surrounded the whole city with a wall, built of large squares of peperine stone, and fortified it on the eastern side behind the Viminal hill, by his celebrated "Agger,"[7] which was finally completed by Tarquin the Proud. All around the wall, on both sides, was a circle of ground, called the Pomœrium, consecrated by the augurs, and held sacred; and it was unlawful to build within its limits, or even to pass the plough over it.[1] This consecrated circle, however, was not necessarily preserved close to the walls, and it was frequently extended without any change being made in the walls themselves. But the boundaries of the city could only be enlarged by those who had made any acquisition of territory to the Roman state.[2] The first who took advantage of this privilege was Sylla, and his example was followed by Augustus, Claudius, Nero, and Trajan.[3] All their improvements, however, consisted in restoring or enlarging the Pomœrium; and no change was made in the walls of Rome till the time of Aurelian, who built a wall round the city, and enlarged it so as to comprehend the Janiculum and the Pincian hill, with great part of the Campus Martius.[4] Various exaggerated accounts have been given of the walls of Aurelian, and antiquaries are much divided respecting them, but their probable compass appears to have been about twenty-one miles. The walls of Rome were repaired during the reign of the emperors Arcadius and Honorius. One-third of them was destroyed by Totila about the middle of the sixth century. His ravages were hastily restored with rude and dissimilar materials, by Belisarius, to stand the second siege. Since that period they have been so often shattered, repaired, and remodelled, that but little of their original structure can now remain.

---

[1] Brocchi's Description of the Soil of Rome; Burgess's Antiquities of Rome, vol. i.

[2] It is impossible to ascertain the precise limits of the city of Romulus, but an outline of it has been traced by Tacitus: "Igitur a Foro Boario, ubi æreum Tauri simulacrum adspicimus, quia id genus animalium aratro subditur, sulcus designandi oppidi cœptus, ut magnam Herculis aram amplecteretur. Inde certis spatiis interjecti lapides, per ima montis Palatini ad Aram Consi, mox ad Curias veteres, tum ad sacellum Larium: Forumque Romanum et Capitolium non a Romulo, sed a Tito Tatio additum urbi credidêre." Tacit. Ann. lib. xii. cap. 24. Compare also Dionysius, lib. ii. cap. 50; and Sextus Aurelius Victor in Romulo.

The Palatine was nearly a square, and hence Rome was sometimes called "Roma Quadrata."

"Et quis extiterit Romae regnare quadratæ?"

Ennius, quoted by Festus.

[3] "Tura ferant, placentque novum pia turba Quirinum.
Templa Deo fiunt, collis quoque dictus ab illo;
Et referunt certi sacra paterna dies."

Ovid. Fast. lib. ii. 507, &c.

Ἱερὸν μὲν οἶν αὐτῷ ἔστι κατεσκευασμένον εν τῷ λόφῳ τῷ Κυρίνῳ προσαγορευομένῳ δι' ἐκεῖνον.

Plutarch. "in Romulo."

[4] Tit. Liv. lib. i. cap. 30. Eutropius in Tull. Host. &c. "Cælium montem intra mœnia clausit, numero et potentia crescente Roma" Vide Messala Corvino, lib. de August. Progen. p. 696. Aug. Histor. &c.

[5] "Aventinum novæ multitudini datum, &c. . . . . Janiculum quoque adjectum, non inopia loci, sed ne quando ea arx hostium esset; id non muro solum, sed etiam ob commoditatem itineris, ponte Sublicio tum primum in Tiberi facto, conjungi urbi placuit." Liv. lib. i. cap. 33.

[6] Liv. lib. ii. cap. 13, &c.

[7] "Aggere et fossis et muro circumdat urbem; ita Pomœrium profert." Tit. Liv. lib. i. cap. 44. See also Plin. Hist. lib. iii. cap. 5.

The number and situation of the ancient gates of the city are involved in hopeless obscurity. Rome at present has sixteen gates, including the four of the *Citta Leonina*, but several of them have been walled up.

Palatine mount.

The Palatine mount is about a mile and a half in circuit, and is nearly square. The ruins of the successive edifices which have stood upon it have raised the soil around its base considerably above the ancient level. About one-half of the surface of it is called the Villa Farnese, which occupies all the north-west side, and about one-half of the two sides contiguous, and is let and cultivated as a kitchen-garden. Adjoining, on the south, is the Villa Spada, which lies along a part of the west side overlooking the site of the Circus. Another part of the hill is covered by the upper and lower gardens. Roncioni, and the side opposite to the Cælian mount, is partly occupied by the convent and gardens of Saint Bonaventura. This celebrated spot, which contained the whole Roman people, till the destruction of the republic, was the site of the dwellings of her senators, and the temples of her gods. But the mansions of the Gracchi, of Hortensius, Crassus, Clodius, Catiline, Cicero, and many others, were all swept away, to make room for the palace of Augustus,[5] which is supposed to have stood on the north-west part of the Palatine, looking down on the *pulchrum littus*, "the beautiful shore" near the Tiber. His successor, Tiberius, erected a dwelling for himself on the north side of the Palatine, looking into the Velabrum.[6] Another was built on the north-east corner fronting the Capitol by Caligula, who joined the Palatium and the Capitol by a bridge thrown across the Forum.[7] But by far the most magnificent was the "Domus Aurea," erected by Nero. The only description on record of this gorgeous palace is that of Suetonius, which we shall give in his own words: "In nothing was he so ruinous as in building. He erected a house extending from the Palatine as far as the Esquiliæ. At first he called it his House of Passage; afterwards, when it had been destroyed by fire and restored again, he gave it the name of the Golden House. To form an idea of its extent and magnificence, it may suffice to state the following particulars. The vestibule admitted his colossal statue, which was 120 feet high. The building was on so large a scale that it had a triple portico a mile long, also an immense pool like a sea, enclosed by buildings, presenting the appearance of towns. There were moreover grounds laid out for tillage, and for vineyards, and for pasturage and woods, and stocked with a vast number of every description of cattle and wild animals. In other respects, every thing was overlaid with gold, embellished with gems, and with mother-of-pearl. The ceilings of the banqueting-rooms were fretted into ivory coffers, made to turn, that flowers might be showered down upon the guests, and were furnished with pipes for discharging perfumes. The principal banqueting-room was round, and by a perpetual motion, day and night, was made to revolve after the fashion of the universe. There were baths streaming with salt and sulphurous waters."[8] "On the ruins of his native country," says Tacitus,[9] "Nero erected a palace, in which the profusion of gold and precious stones did not raise the chief admiration, for these were ornaments that widely-diffused luxury had rendered common; but universal astonishment was excited by its spacious glades, and large artificial lakes, by its thick woods and shades, like vast wildernesses, by its ample lawns and avenues, and far extended prospects." The successors of Nero made various alterations on the imperial palace. It suffered by fire for the third time under Commodus.[10] The Goths and Vandals, in the fifth century, pillaged it of most of its treasures, but they do not appear to have rendered it uninhabitable; for even so late as the beginning of the seventh century Heraclius held a state ceremony in the palace of the Cæsars. Its final destruction seems to have been in a great measure the work of the Farnese popes and princes, who carried off its materials to build their palaces and villas, and buried its magnificent halls beneath their wretched gardens. Many extensive chambers and halls have at different times been discovered, but after being rifled of their statues and ornaments, they have all been filled up again. The whole mount is now one mass of confused and undistinguishable ruins. The very soil is formed of crumbled brick-work. Nothing has been told, nothing can be told, to satisfy the belief of any but a Roman antiquary.

Palace of the Cæsars.

Capitoline hill.

The celebrated Capitoline hill, the least of all in extent, but greatest in fame and importance, is 470 yards long and 185 broad, and contains about sixteen acres. It exhibits two summits separated by a valley, which is called by antiquaries the *Intermontium*. The height of this hill has been materially diminished, both by the ruins around its base, and by the repeated earthquakes that have shattered the friable tufa of which it is composed, and have thus both lowered the actual height and filled up the base. On the summit of this famous mount

Capitol.

> ——— the Capitol,
> Above the rest, lifted his stately head;
> On the Tarpeian rock her citadel,
> Impregnable.

Here also stood the temple of Jupiter Feretrius, the temple of Jupiter Capitolinus, and many other interesting objects. The temple of Jupiter Optimus Maximus was one of the largest and most splendid of the ancient world. Its roof was of burnished gold, the pavement of the finest materials, the columns were of precious marbles, the doors of bronze overlaid with gold, the statues of ivory; and many other objects of surpassing costliness and art embellished the whole interior.[1] In the centre of the temple was the statue of Jupiter Capitolinus seated on a throne of gold, with Juno on his left, and Minerva on his right side. This splendid edifice was destroyed during the civil wars between Marius and Sylla, but was shortly after rebuilt by the latter, who enriched it with the spoils of Greece. It was a second time destroyed by fire during the bloody conflict that took place in the Capitol between the partisans of Vitellius and Vespasian.[2] The Capitol rose again from its ashes, with renewed splendour, and through the liberality of Vespasian, and especially of his son Domitian, it greatly surpassed its former magnificence. Its immense wealth appears to have remained untouched till the time of Honorius, when the necessities of that emperor forced him to lay hands upon the gold which ornamented it; and about seven years after his death, it was completely despoiled of its treasures by Genseric king of the Vandals. Of all the ancient splendours of the Capitoline hill, scarcely a vestige now remains. Its invulnerable citadel, its temples and golden statues, its triumphal arches and splendid porticoes, all have been swept away, and its very name is now almost lost in the semi-barbarous appellation, Campidoglio. At present the Capitoline mount is covered with buildings, which, although not devoid of elegance, are unworthy of a spot which was once so august.

At the base of the northern and principal ascent to the Capitol, are two colossal lionesses of Egyptian porphyry, pouring a stream of water into spacious basins of marble; and at the top of the ascent are two ancient colossal statues of Grecian marble, representing Castor and Pollux standing by the side of their horses. Here we enter the square, supposed with great probability to be the *Intermontium*, in the centre of which stands the equestrian statue of Marcus Aurelius. In front, and on each side, are three palaces, erected by Michael Angelo; that of the senators, the conservatori, and the statue gallery. The Museum Capitolinum contains a splendid collection of busts, statues, sarcophagi, &c., and the staircase is lined with an old plan of Rome, which formed originally the pavement of a temple in the forum, but unfortunately it is not entire. Beneath the senators' palace are the remains of an ancient edifice, supposed to have been the *Tabularium*, where the laws and public records were suspended on tables of bronze; and in its stables, cellars, and gardens, are considerable remains of the ancient fortifications of the citadel. Near the base of the Capitoline hill are the remains of the Mamertine prisons, built (according to Livy) by Ancus Martius. A lower cell, called the Tullianum, was added by Servius Tullius.[3] There are still two dungeons remaining, an upper and a lower; and in ancient times, prisoners who were condemned to be strangled, or to die of hunger, were thrust down into the lower cell by a circular aperture called Robus. It was in these dungeons that Jugurtha was suffered to die of hunger.[4] Here the accomplices of Cataline, when, through the influence of Cicero's eloquence, they were condemned to immediate death, were conducted from the senate house and strangled.[5] Here too Sejanus, the minister of Tiberius, met the just punishment of his crimes;[6] here Perseus, the captive king of Macedonia, lingered in hopeless confinement; and here Simon, the bravest of the Jewish leaders, was put to death, while Titus ascended in triumph to the temple of Jupiter Capitolinus.[7] The northern and highest summit of the Capitoline mount is occupied by the church and monastery of Ara Cæli; and on that part of the hill which lies towards the river, is the

> steep Tarpeian,
> The promontory whence the traitor's leap
> Cured all ambition.

Aventine hill.

The Aventine, well known for the unpropitious augury of Remus, is the most western of the seven hills. It is separated from the Palatine by the valley of the Circus Maximus, and the Tiber flows round its northern base. It has two distinct summits, which are divided by a valley. On this mount stood the famous temple of Diana, erected in the joint names of all the Latin tribes. Here also stood the temple of Juno Regina; the temple of the Bona Dea; the temple, portico, and library of Liberty, the first public library in Rome.[8] But of these, and many other magnificent and celebrated edifices, no traces now remain, nor is their place supplied by any buildings, even of modern times, except some decaying churches and half deserted convents.

Cælian hill.

The Cælian, which is the most southern of the seven hills, is of a triangular form, and is crossed by the lofty and ruinous arches of Nero's aqueduct It is stated by Tacitus, that this mount was originally called *Querquetulanus*, from the quantity of oak trees that grew upon it; and that it received its name from Cælius Vibenna, an Etruscan chief, who inhabited some part of it when he came to the succour of Tarquinius Priscus.[9] Tiberius commanded that it should be called Mons Augustus, but the intention was never carried into effect.[10] The name of Lateran has prevailed in modern times, derived from a senator named Lateranus, who had a splendid edifice upon it in the time of Nero.[11] Deserted as it now is, the Cælian mount was once covered with temples and monuments of magnificence; but of these splendid buildings every trace has long since vanished, and the surface of the hill is strewed over with shapeless ruins, of which the date, the author, and the object, are alike unknown. The only buildings worthy of particular attention are the curious and interesting church of San Stephano Rotondo, which is universally admitted to be an ancient temple, though antiquaries are by no means agreed respecting the name of its tutelar god; and the sumptuous basilica of St. John Lateran, which stands on the eastern summit of the hill.

Esquiline hill.

The Esquiline is more extensive than any of the rest, and more irregular in its form. It is partly covered with the buildings of modern Rome, and partly abandoned to desolation. The Esquiline hill was added to Rome by Servius Tullius, and it was in his flight from the senate-house, to his palace on the Esquiline, that he was murdered by the emissaries of Tarquin his son-in law. A street called *Vicus*

Sceleratus, between the forum and the Esquiline, was the scene of his daughter's horrible impiety, when she caused her chariot wheel to pass over the body of her father.[1]

Before the Augustan age, the Esquiline mount was inhabited by the meanest of the Roman people; and in that part of it which was without the wall their unburied bodies were promiscuously deposited.[2] Mæcenas having received a present of the ground from Augustus, covered it with gardens and groves, and erected on its summit a palace.[3] On this mount Julius Cæsar was born. Here also was the house of the younger Pliny, part of Nero's golden house, and the palace and baths of the emperor Titus. Here Virgil also is said to have had a house, near the palace of his patron Mæcenas. It is stated by Suetonius, that Horace was buried near the tomb of Mæcenas, at the extremity of the hill.[4] The Esquiline mount has two summits, the Cispius, on which stands the basilica of Santa Mari Maggiore, and which was supposed to have been anciently occupied with the temple of Juno Lucina; and the Oppius, crowned with the church of St. Pietro in Vincula, built upon a part of the extensive baths of Titus. Toward the extremity of the Esquiline, and not far from the Porta Maggiore, in a vineyard, stands a ruined edifice called the temple of Minerva Medica. Nothing now remains but the walls and part of the vaulted roof. Many beautiful statues have been found in the grounds that border it.

iminal ll.

The Viminal hill, which probably derived its name from the osiers *(vimines)* that grew upon it,[5] lies between the Esquiline and the Quirinal, but the fall of the ruins from these hills has rendered it almost impossible to recognize it. The only conspicuous object upon it is the church of S. Lorenzo in Pane Perna, with its adjoining buildings and vineyards. Near the Viminal hill stood the celebrated prætorian camp, which forms such a distinguished object in the decline of the Roman empire.

uirinal l.

The Quirinal hill was adorned in ancient times with the famous temple of Romulus Quirinus. On the opposite side, the magnificent temple of the Sun, built by Aurelian, is supposed to have stood. The Quirinal is the only one of the seven hills that is populous. It is covered with palaces, churches, streets, and fountains. But the only remains of antiquity that it can now boast, are the vestiges of the baths of Constantine, in that part of the Colonna gardens which overlooks the Piazza Pilotta, and a considerable part of the baths of Diocletian, one of the grandest remains of ancient splendour.

rum.

The site of the Roman Forum is between the Palatine and Capitoline hills. Its present surface is from fifteen to twenty feet above its ancient level, and various excavations are now making in it in the hope of discovering some relics of antiquity. "Here were held the comitia, or assemblies of the people; here stood the rostra from which the orators harangued them; the curia, or senate-house; the basilica, or courts of justice; the public tribunals, the statues and memorials of great men, and some of the most sacred temples of religion." After the destruction of the republic, another forum was built by Julius Cæsar; and his example was followed by Augustus, Nerva, Domitian, Trajan, Vespasian, and Antoninus Pius. The only remains of antiquity that now stand within the limits of the Roman forum are those commonly designated as the triumphal arch of Septimius Severus, the temple of Jupiter Tonans, the temple of Fortune, and the temple of Concord, and the solitary column dedicated by the Greek Exarch, Smaragdus, to the emperor Phocas, the ruined wall of the curia, and the three beautiful columns near the base of the Palatine hill, generally called "the disputed columns." Of the immense number of other buildings of all kinds, temples, basilicas, columns, statues, which once stood here, not a vestige now remains, and their very situations are a matter of bitter dispute. At the north-east corner of the Forum is the church of Santa Martina and St. Luke, which is supposed, with some probability, to occupy the site of the beautiful temple of Mars the Avenger, erected by Augustus. Near it is the church of St. Adrian, called *in tribus foris*, from the Roman forum, and the forums of Julius Cæsar and Augustus, of which it forms the connecting point. Behind these are three fluted Corinthian columns, and one pilaster of Parian marble, of the grandest and most perfect style of architecture, supposed to be the remains of the forum of Nerva. To the eastward, and at the base of the Quirinal hill, is the forum of Trajan, the centre of which has been excavated, down to the level of the ancient pavement, by the French. Here stood the famous equestrian statue of Trajan, which excited the admiration and envy of Constantine,[6] and many other honorary statues of distinguished individuals; and here still stands the triumphal column of Trajan, the finest in the world. This superb pillar is of the finest white marble, about 128 feet in height, and is covered with sculptured figures representing the wars and triumphs of the emperor Trajan. The ascent to the summit is by a winding staircase of 185 steps of solid Parian marble. A little to the north is the triumphal column of Marcus Aurelius, formed of the same materials and workmanship, though inferior in the beauty and perfection of its sculpture to that of Trajan. These columns formerly supported each a colossal statue of Trajan and Marcus Aurelius, but they have long since disappeared, while bronze statues of the apostles Peter and Paul have been substituted in their stead. In a deserted spot, which was once the forum boarium, or cattle-market of Rome, there is a magnificent four-fronted arch, commonly called Janus quadrifrons, which is the only one now remaining of the many ancient Jani of ancient Rome. It is built of immense blocks of Grecian marble, now so darkened and discoloured by time, and covered with bushes and ivy, that it has a peculiarly picturesque and venerable appearance. Near this arch, by passing under some low brick vaults opposite the church of S. Giorgio in Velabro, the best view is obtained of the celebrated "Cloaca Maxima," unquestionably the most ancient of all the ruins of Rome, and the only remains of the work of her kings. This stupendous and useful work was executed by Tarquinius Superbus.[7] In ancient times the arches were so large, that it is stated by Strabo and Pliny, that a waggon load of hay might pass through them.[8] Though greatly choked up by the elevation of the soil of modern Rome, it still, after a lapse of 3000 years, serves as the common sewer of the city. Almost close to the cloaca maxima is the far-famed fountain of Juturna.[9]

Trajan's pillar.

Cloaca Maxima

Proceeding along the Via Sacra, we come to some ruins which are supposed to be the remains of Vespasian's temple of Peace, built at the close of the Jewish war. It was one of the most magnificent temples of antiquity, and within it were deposited the spoils taken from the temple of Jerusalem. Others maintain, however, that these ruins belonged to the basilica of Constantine. Crossing to the opposite side, and passing under the broken and defaced triumphal arch of Titus, we behold the majestic ruins of the mighty Coliseum. This stupendous building was erected by Vespasian and Titus, on the spot which had previously

Statistics of Rome.

been covered with the pools belonging to the "golden house of Nero." Owing to the stability of its construction, it survived the era of barbarism, and was so perfect in the thirteenth century, that games were celebrated in it for the amusement of all the nobility of Italy. Its destruction was, in a great measure, the work of the Romans themselves, who carried off the materials to build their own dwellings.

> ——From its mass
> Walls, palaces, half cities have been rear'd ;

till at length Benedict XIV. secured it from further dilapidation, by erecting a cross in the middle of the arena, and proclaiming it to be consecrated ground, hallowed by the blood of the martyrs. The form of the Coliseum is elliptical ; the length measures $591\frac{1}{4}$ feet, and the breadth $508\frac{3}{4}$; it is $1683\frac{3}{4}$ feet in circumference, and 147 in height. The exterior elevation presents four divisions or storeys, of which the three lower are supported by half columns, and the uppermost by pilasters. The interior elevation, beginning from the arena, presented first the podium, a kind of covered gallery, destined for the use of the emperor and persons of the first description ; then three successive orders of seats for the spectators, called collectively the cavea; and at the top the attic, with the velarium or awning. It has been calculated that the cavea, with the podium, could contain 80,000 persons seated ; but taking into account the upper gallery, and the number of persons necessarily engaged about the arena, that not less than 100,000 souls have sometimes been contained within these walls. At the dedication, which lasted one hundred days, 5000 wild beasts were exhibited and slain.[1] The arena also was overflowed with water, and made the scene of a mock naval fight. The northern side is pretty entire ; but on the south, the stupendous arches have been stripped of their external decorations. In the interior the destruction is more complete ; the marble steps are all torn away, the steps and vomitories overthrown, and the sloping walls and broken arches are covered with weeds and shrubs. Around the arena the pictured representations of the fourteen stages of our Lord's passion are placed at regular intervals. In the centre of it stands a huge black cross, which offers the liberal recompense of one hundred days' indulgence to every person who devoutly kisses it. A broad pathway runs through the middle ; the rest is covered with a smooth green sod. "Here," says Mr. Forsyth, "sat the conquerors of the world, coolly to enjoy the tortures and death of men who had never offended them. Two aqueducts were scarcely sufficient to wash off the human blood which a few hours' sport shed in this imperial shambles. Twice in one day came the senators and matrons of Rome to the butchery. A virgin always gave the signal for slaughter; and when glutted with bloodshed, those ladies sat down in the wet and steaming arena to a luxurious supper. Such reflections check our regret for its ruin. As it now stands, the Coliseum is a striking image of Rome itself, decayed, vacant, serious, yet grand, half grey and half green, erect on one side and fallen on the other, with consecrated ground in its bosom ; inhabited by a beadsman, visited by every cast; for moralists, antiquaries, painters, architects, devotees, all meet here to meditate, to examine, to draw, to measure, and to pray."[2]

Circus Maximus.

Between the Aventine and Palatine hills stood the Circus Maximus, which occupied the whole valley; and though all traces of the building have disappeared, its form is still very apparent. This circus was first laid out by Tarquinius Priscus ;[3] but it does not appear to have attained any great degree of splendour till the time of Julius Cæsar, who enlarged the whole space, and rendered it capable of containing 150,000 spectators. Pliny states that in the time of Trajan it held 250,000.[4] It was the last place where games were celebrated in Rome. So late as the close of the fifth century, it was filled for the last time with spectators of the gladiatorial combats, when Telemachus, an Asiatic monk, having ineffectually tried remonstrance, descended into the arena to separate the combatants, and was stoned to death by the enraged people. But the sacrifice was not made in vain, for from that day Honorius abolished the combats of gladiators. The last remains of the Circus Maximus were removed by Paul III., "that universal destroyer of antiquities." Attached to this circus were the shops or *tabernæ*, in which, during the reign of Nero, began the conflagration that consumed ten out of fourteen quarters of the city. Of all the circuses of ancient Rome, one only is sufficiently entire to shew what a circus was. It stands on the Via Appia, beside the tomb of Cecilia Metella, and is called the circus of Caracalla, though there is no reason for believing it to have been built by that emperor. It is still in excellent preservation.

On the outside of the Coliseum are the mouldering ruins of a building, supposed to have been that famous fountain the Meta Sudans, which existed even in the time of the republic.[5]

Pantheo

One of the most attractive of the ancient edifices of Rome, is the Pantheon or Rotondo, "the pride of Rome." That glorious combination of beauty and magnificence, which was erected by Agrippa, is 132 feet in height, the same in diameter, and 396 feet in circumference. It is generally believed that the body of the building is of earlier erection than the portico ; that it was built for a thermal hall, or something belonging to the baths of Agrippa, and that the portico was afterwards added in order to convert it into a temple. It has long been a matter of dispute to whom the Pantheon was dedicated. The popular belief is, that it was dedicated to Jupiter and all the gods of antiquity ; but Pliny expressly says that it was dedicated to Jupiter the Avenger.[6] In the year 608, Pope Boniface IV. obtained permission of the emperor Phocas to consecrate it for a Christian church. It then received the title of St. Maria Rotondo, which it still preserves. About fifty years after its consecration, Constans II. stripped off the bronze covering of the roof, the bronze bassi relievi of the pediment, and the silver which adorned the interior of the dome, and carried away the spoil to send it to Constantinople ; but being murdered at Syracuse on his return, these ornaments were afterwards conveyed by the Saracens to Alexandria. In 1632, Pope Urban VIII., one of the Barberini family, carried off all the bronze that was left, and moulded it into ornaments for St. Peter's tomb in the Vatican, and cannon for the castle of St. Angelo. It has been calculated that upwards of forty-five millions of pounds weight of metal was taken away on that occasion. This gave rise to the pasquinade, "Quod non fecerunt Barbari Romæ, fecerunt Barberini." The same pope disfigured the building by placing before the dome two hideous belfries, as a perpetual monument of his wretched taste. As a sort of compensation, however, he replaced one of the three deficient columns of the portico. The other two were restored by Pope Alexander VII. The portal has been pronounced to be "positively the most sublime result that was ever produced by so little architecture." The original folding doors are said to have been carried off by Genseric; but the present gates are obviously ancient also, and are supposed to have been taken from some other Roman building. The four grand recesses in the interior, each supported by two magnificent columns, and two pilasters of giallo antico, are truly beautiful; but the niches in the intermediate spaces are wretchedly mean, and in bad taste. Behind the altars which crowd the principal recesses, are placed on shelves the busts of the most distinguished men of modern Italy. The pavement, which is supposed to be the work of Septimius Severus, is composed of porphyry and yellow marble, and of pavonazzetto, laid down in large slabs, alternately round and square. The splendid dome which rises over the whole is still uninjured. A large circular aperture at the top, surrounded with a girth of metal, admits a flood of light sufficient to illuminate the whole building. The remains of Raphael are interred in the Pantheon, together with many of those whose names reflected lustre on modern Italy in her proudest days. The situation of the Pantheon is extremely unfavourable. It is sunk in the dirtiest part of modern Rome. The congregated filth of the pavement, the incessant uproar, and the crowds of clamorous beggars, tend materially to lessen the enthusiasm with which the spectator gazes upon this monument of the taste and magnificence of antiquity. Yet in spite of all this, and of the dilapidations which it has suffered from the lapse of eighteen centuries, and the rapacity of barbarians, still, under every disadvantage, it is pre-eminently beautiful. "The pure and perfect architecture, the greatness of design, the harmony, the simplicity, and the imposing majesty of the whole, command our never satiated admiration, our approbation, and our praise." "Though plundered of all its brass, except the ring which preserves the aperture above; though it has been twice the prey of fire; though it is always open to the rain, and is sometimes flooded by the river, yet no monument of equal antiquity is so well preserved as this rotondo."[1]

Temple of Vesta.

Near the Tiber there is a beautiful little temple, popularly called the temple of Vesta, though no satisfactory reason can be given for the designation. Its form and elegance have been much admired; and bronze models of the "little temple of Vesta" are dispersed over most of Europe. It is entirely built of Parian marble, and its portico is composed of a circular colonnade of twenty fluted Corinthian columns. Of these only one is wanting; but all the architrave is lost. The small circular cell within the colonnade is now converted into a chapel, dedicated to "La Madonna dell' Sole," (the virgin of the sun.)

Churches.

Opposite to this beautiful building, stands the church of St. Maria in Cosmedin, built by Adrian I. on the ruins of an ancient temple, the name of which is unknown. It appears, like the Pantheon, to have eight columns, and fifteen at the sides. Six of the front columns of the most beautiful Parian marble may still be traced, built up into this hideous compound of deformity and bad taste. The church of S. Maria Egizziaca has been formed out of another ancient temple, which is usually called by the name of Fortuna Virilis. On that ruin-covered spot, which now bears the name of the Roman Forum, but without its ancient limits, stands the temple of Antoninus and Faustina. It is a fine specimen of ancient architecture. Its noble portico, which, though entire, has evidently suffered from fire, is composed of six Corinthian columns of Cippollino marble in front, and two on each side. The exquisite chiseling of the friese and cornice, the sculptured griffins, candelabras, vases, &c. which form the ornaments, are scarcely equalled in any Roman monument of the kind in existence. A little farther on is the church of the saints Cosmo and Damiano, supposed to be the double temple of Romulus and Remus. Near the Coliseum are the remains of Hadrian's magnificent temple of Venus and Rome.[2] Some striking ruins of the interior of the fabric still exist in the middle of the site. Pope Honorius I. covered the whole of St. Peter's basilica with bronze tablets which he took from the roof of this temple.

Many other ruins of the magnificent temples of ancient Rome are scattered throughout the city, but their remains are so scanty that it is impossible to obtain any information respecting their origin or extent.

Theatres.

Various temporary theatres seem to have been erected at different times in Rome, but the first that was built of stable materials in this city was the theatre of Pompey. It was rebuilt by Tiberius, and again by Claudius, but there is not a single vestige of it now remaining. The theatre of Marcellus was built by Augustus, who named it after his nephew, whose death has been commemorated by Virgil in such pathetic strains.[5] Of this once magnificent edifice nothing now remains except a very small portion of the two lower arcades, which are considered models of architecture.

Porticos.

Ancient Rome possessed a number of noble porticos, but all that now remains of these is a fragment of the portico of Octavio. It originally consisted of a double line of marble columns covered with a roof, so as to afford shelter to those who walked within it. In the open square stood the temples of Jupiter and Juno, the first in Rome that were built of marble. Here were exhibited many splendid paintings and statues; and this portico contained one of the three public libraries which Rome possessed in the Augustan age. The only remains of this magnificent building are four Corinthian columns, and three pilasters of beautiful marble, with a part of the ancient pediment. They stand in what a modern traveller has pronounced the "filthiest spot upon the whole face of the globe—the pescheria or fishmarket, the crowded quarter where the Jews are condemned to reside."

Thermæ, or baths.

It has been justly said that no monument of ancient architecture is calculated to inspire such an exalted idea of Roman magnificence, as the ruins of their thermæ, or baths. These magnificent structures were not, however, erected for bathing alone; but in them there were rooms for almost every kind of athletic exercises; walks shaded by rows of trees; fountains adorned with statues and precious marbles; libraries; spacious halls and vestibules decorated with the finest objects of art, where poets recited, orators declaimed, and philosophers lectured. A splendid description has been given by Pliny of the sculptures and paintings, the magnificent seats of solid silver, the silver pipes and baths, the polished vases, the pavements of precious stones, and all the sumptuous decorations of these magnificent buildings dedicated to the luxury and idleness of the Romans.[4] The thermae of ancient Rome are known to have stood in all their original magnificence so late as the fourth century, and their destruction seems to have been almost entirely owing to the rapacity of the modern Romans. Of all the thermae that adorned imperial Rome, the ruins of those of Titus, Diocletian, and Caracalla, are all that now remain in any considerable degree of preservation. The thermae of Caracalla are situated at the base of Mount Aventine, on the Via Appia. They were left incomplete by Caracalla, and were finished by Heliogabalus, and by Alexander Severus.[5] These baths, together with the outworks, were one mile in circumference, and their ruins still cover a vast extent of ground; but it is impossible to form from them any idea of the peculiar destination of the particular parts. They form a succession of immense halls, in the midst of which some aged trees have taken root in the soft green turf which now supplies the place of the pavement of costly marble and rich mosaic. One of these halls, the famous Cella Soleares, held 1600 seats of polished marble,[1] and was entirely covered with a flat roof of stone, supported by cancellated work of brass or copper, which, from the resemblance to the lacing of a sandal, is supposed to have given the hall its designation. On the western side of the ruins there are the remains of a rotondo, and a great number of smaller divisions of all sizes and forms. This enormous fabric was adorned with an immense number of statues and paintings. The celebrated Farnese Hercules, the Glycon, the bull, now in the museum at Naples, the Torso Belvidere, the Flora, the Callypigean Venus, together with many other statues, columns, bas reliefs, &c., were all found in these ruins. The thermae and palace of Titus were built with the materials, and on the site of the buildings and pleasure grounds, of Nero's golden house. They were finished or enlarged by Trajan, and afterwards repaired and embellished by Hadrian. They appear to have been of remarkable extent and magnificence. Part of the theatre of one of the temples, and of one of the great halls, still remains above, and many vaults and long galleries under ground. Some of these subterraneous apartments are curiously painted, and the ceiling of one of them contains some most exquisite specimens of paintings in arabesque, which afforded a model to the genius of Raphael, and enabled him to restore an art which had been lost for so many centuries.[2] In the time of Leo X. some excavations were made, and the famous group of the Laocoon was discovered in one of the halls, and several pillars of granite, alabaster, and porphyry, have since been found in various partial researches. In another part of the Esquiline Hill stand the Sette Salle, nine halls of one hundred feet in length, by fifteen in breadth, and twenty in depth, which have evidently been immense reservoirs of water, to supply the baths of Titus, and occasionally the enormous arena of the Coliseum, when naval engagements were represented.

---

[1] Rome in the 19th Century. Forsyth's Italy, p. 147.

[2] Vide Dion. Cassius, Hist. Rom., lib. lxix. p. 1153.

[3] Æn. lib. vi. 861.

[4] Pliny, lib. xxxiii. cap. 12. Rome in the 19th Century, vol. ii. p. 83. Seneca. Epist. 86. Statius.

The thermae of Diocletian, which are scattered over the summit of the Quirinal and Viminal hills, are said to have surpassed all the thermae of ancient Rome in extent and splendour. One of the circular halls has been converted into a granary, another into the church of St. Bernard. The *xystum penacotheca*, or great covered hall of the thermae, has been transformed into the church of St. Maria degli angeli, and still retains much of its original grandeur. It is 350 feet in length, 80 in breadth, and 90 in height. It was paved and incrusted with the finest marble by Benedict XIV. The vaulted roof is supported by sixteen Corinthian columns, eight of which are ancient, and are formed of one vast piece of Egyptian granite. This noble edifice is adorned with a variety of paintings; among others, with the martyrdom of St. Sebastian, by Domenichino; and the circular vestibule contains the monuments of Salvator Rosa and Carlo Maratti.

Bridges.

Seven bridges formerly conducted over the Tiber to the Janiculum and the Vatican Mount. Three of these, the Pons Sublicius, the Pons Palatinus, and the Pons Triumphalis, were long ago destroyed. Those which now remain are the Bridges of the Island, the Ponte Sisto, and the Ponte San Angelo. Out of Rome there is only one bridge over the Tiber, the famous Milvian or Æmilian bridge, now corrupted into Ponte Molle. Here the ambassadors of the Allobroges were seized by the vigilance of Cicero;[3] and here was fought the eventful battle in which Constantine defeated Maxentius. About three miles from Rome, the Anio, now the Teverone, is crossed by the Ponte Lamentano, formerly the *Pons Nomentanus*, beyond which rises the broad green height of Monte Sagro, the famous *Mons Sacer*, to which the Roman army and people twice retired from the tyranny of the Patricians.[4] The Ponte Salario, a very singular and picturesque structure, which also crosses the Anio, about three miles beyond the gate of the same name, was the scene of the celebrated combat between Manlius Torquatus and the gigantic Gaul.[5] The ground on the other side of it is supposed to be that on which Hannibal encamped during the few days he remained before Rome.

Triumph arches.

Rome contains the ruins of a number of triumphal arches. The most important of these are the arches of Titus, of Septimius Severus, and of Constantine. The arch of Titus is the oldest triumphal arch now existing in Rome. It is peculiarly rich in sculpture. The interior is decorated with two fine bas reliefs, representing on one side Titus in his car of triumph, and, on the other, the spoils of the temple of Jerusalem and the captive Jews. It was greatly mutilated, but has been recently restored. The arch of Severus, though more entire, is much less beautiful. The arch of Constantine is thought by far the most noble of the triumphal arches of Rome, but its columns, its beautiful sculptured medallions and bas reliefs, have evidently been pilfered from one of the triumphal arches of Trajan.

Aqueduc

Of all the stupendous aqueducts of ancient Rome, two alone remain even in ruins, the Martian and the Claudian. The former, which was built by Quintus Martius Rex the prætor, 125 years B. C., conveyed to Rome three different waters in three distinct channels; the latter was built by the emperor Claudius, and conveyed two waters to Rome, the aqua Claudia, and the Anio vetus. The first was conveyed a distance of thirty-five, the last of sixty-two miles. There is reason to believe that the aqueducts were destroyed by Totila, but notwithstanding their destruction, Rome is still the city in the world the best supplied with water, three popes having conducted to it three noble streams.[6]

Rome alone, of all the cities of the world, boasts those sublime monuments of antiquity, the obelisks of Egypt.[7] The most important of these are the obelisk that stands in the Piazza del Popolo; it was the first ever seen in Rome, and was brought from Egypt by Augustus, and placed in the Circus Maximus, where it served as the gnomon of a dial; the obelisk in the grand piazza of St. Peter's, brought from Egypt by Caligula; the obelisk in front of the Lateran church, the largest of them all, transported from Egypt by Constantius; the obelisk mentioned by Pliny, which was brought to Rome by Augustus, and erected in the Campus Martius; it now stands on Monte Citorio; and the obelisk which stood in the circus of Sallust, and now crowns the lofty summit of the Pincian hill.

Tombs.

The Roman tombs were distinguished by their impressive grandeur and magnificence. All along the long line of the Appian way are the mouldering remains of the ruined and blackening sepulchres,

> "Where Cæsars, heroes, peasants, hermits lie,
> Blended in dust together."

But among the immense number of proud sepulchres of the most distinguished Romans which crowded that "Queen of ways," all, with a very few exceptions, are unknown. About sixty years ago the tomb of the Scipios was brought to light, but "the Scipios tomb contains no ashes now." Exactly on the opposite side of the road to it is the sepulchre of the Maniglia family. The tomb of Cecilia Metella, the daughter of Metellus, and "the wealthiest Roman's tatistics Rome.

wife," is generally acknowledged to be a most beautiful sepulchral monument.[1] It consists of a round tower formed of immense blocks of Tiburtine stone fixed together without cement, and adorned with a Doric marble frieze finely sculptured. This beautiful tower was at one time turned into a fortress by the family of the Gætani. In the sepulchral vault was found the beautiful marble sarcophagus of Cecilia Metella, now in the Palazzo Farnese. Near the Porta San Paolo, in the "Prati del Popolo Romano," ("the meadows of the Roman people,") stands the grey pyramid of Caius Cestius. It rises about a hundred and twenty feet in height, and is entirely built of marble. Its form is graceful, and its appearance very picturesque. The "Prati del Romano" are planted round with mulberry trees, and now form the burial place of foreigners, excluded by their religion from the other cemeteries. By far the greater part of the strangers interred here are English.

tacombs

The extensive catacombs found about Rome owe their origin to the large excavations which were made by the Romans for obtaining pozzolano, an immense quantity of which they used, and exported for sand and mortar, and other purposes. These subterraneous labyrinths branch out many miles in various directions. Those under the church of St. Sebastian alone are said to have been explored to the extent of above fifteen miles. Those dreary regions afforded shelter to the first Christians during the dreadful persecutions which they suffered under the emperors. They were also used as sepulchres, but all the bones which they once contained have been carried off as precious relics. The chambers are all square, with arched recesses, and rectangular gaps, both in the walls and flooring, to receive coffins.

ilica.

Peter's.

It has been said that perhaps no city in the world abounds with such numbers of churches as Rome, or with fewer handsome ones as respects their architecture. Many of the old churches of Rome are still called basilica,[2] but that title properly belongs to the following seven, St. Peter's, St. John Lateran's, Santa Maria Maggiore's, S. Paolo *fuori le muro*, Sante Croce in Gierusalemme, S. Sebastiano, and S. Lorenzo *fuori le muro*. St. Peter's is the finest church in the world, excelling all others, not only in magnitude but in beauty. It was projected by Pope Nicholas V. in the middle of the fifteenth century; it was not, however, till the pontificate of Julius II. in 1506, that the first stone of the edifice was laid, and the whole building was not finished till the year 1621, during the pontificate of Paul V. No fewer than twenty-four popes, counting from Nicholas V., assisted in the erection of this magnificent structure. It is said to cover twenty acres, and to have cost many millions sterling. It is entirely built of Travertine stone, which looks as bright and fresh as if newly finished. The length of the building is 609 feet, and of the transept 500 feet, the height of the dome is 440 feet, the height of the nave 154, and its breadth 90 feet. The plan of the building was frequently changed. The original architect was Bræmante, but the greater part was from the design of Michael Angelo, which, however, has unfortunately been marred by Paul V. and Carlo Moderni, justly stigmatized as "a wretched plasterer from Como, who broke the sacred unity of the master-idea, and whom we must execrate for the Latin cross, the aisles, the attic, and the front."[3] From the front of the church on either side, a grand semicircular colonnade, composed of four rows of columns, sweeps round and encloses the immense circular area, in the centre of which stands a noble Egyptian obelisk of red granite, between two most beautiful fountains. The general effect is greatly injured by the Vatican Palace, which is built on one side of St. Peter's, overlooking the top of the colonnade, and destroying its uniformity. A covered portico extends along the whole breadth of the building, vaulted with gilt stuccos, and paved with various marbles. It lengthens on the eye by a grand succession of doors, niches, statues, and fountains, till the perspective terminates with the equestrian statue of Charlemagne. The nave is infinitely grand and sublime, and is impannelled with the rarest and richest marbles, and adorned with every art of sculpture and of taste.

Statistics of Rome.

The splendid canopy of the great altar, and the wreathed columns which support it, were formed out of the bronze taken from the Pantheon by Urban VIII. A double marble staircase leads down to the confessional or tomb of St. Peter, illuminated by more than a hundred never-dying lamps. His sepulchre is surrounded by a circular vault, which is lined with the tombs of popes, saints, emperors, and deposed or abdicated princes, among whom are the last of the Stuart family, the emperor Otho, &c.

The stupendous dome, viewed in its design, its altitude, or even its decoration, is altogether unrivalled, and has justly been pronounced the triumph of modern architecture. A broad paved road leads up to the top of the church, and from thence the dome may be ascended by a succession of ingeniously contrived staircases. From the top an extensive prospect may be obtained of the beautiful amphitheatre of hills which encloses the Campagna. The summits of the loftier Apennines behind, wreathed with snow; the Tiber in its sinuous windings through the waste; in the distance the blue waters of the Mediterranean gleaming in the sunbeams; and, far beneath, Rome, with her churches, her palaces, her dark and distant ruins, the rich verdure, and golden fruit of the orange gardens of her convents, contrasting with the deep shade of their mournful cypresses.[4]

St. John Lateran.

The church or basilica of St. John Lateran was built by Constantine, and during many ages before the erection of St. Peter's church, was regarded as the mother of churches, and head of the Christian world. It derived its name from Plautius Lateranus, the leader of the first and unsuccessful conspiracy against Nero.[5] This church has been frequently rebuilt, enlarged, and improved, and the old architecture now lies completely concealed in the modern. It is a very large but by no means handsome building, and its architecture is deformed by many glaring defects.

St. Paul's.

The old basilica of St. Paul, founded by Constantine, and rebuilt by Honorius, contained a hundred and twenty pillars

---

[1] There is a stern round tower of other days,
Firm as a fortress with its fence of stone,
Such as an enemy's baffled strength delays,
Standing with half its battlements alone,
And with two thousand years of ivy grown,—
The garland of eternity, where waves
The green leaves over all by time o'erthrown.
What was this tower of strength? Within its cave
What treasure lay so lock'd, so hid? A woman's grave.
Childe Harold, c. iv. st. 100.

[2] "A *basilica* seems at first to have been part of a palace. It is sometimes represented as a simple portico. It then included the buildings which were afterwards annexed. Some of these buildings which had served as *basilica* for law and trade, became places of worship to the primitive Christians, and the first churches that were erected expressly for that worship, erected perhaps on the site of some ancient basilicæ, retained the same name."—*Forsyth's Italy*, p. 87.

Statistics of Rome.

of the rarest marble and granite, the spoils of some of the noblest edifices of antiquity. A few years ago this church was destroyed by fire, but it is now rebuilding in a style of great magnificence.

St. Clement's.

The church of St. Clements on the slope of the Esquiline has the reputation of being the oldest existing church in the world. The churches of the Jesuits and of St. Ignatius are distinguished for their riches, and the immense number of ornaments which they contain. The church of Santa Maria sopra Minerva, built on the site of Pompey's temple of Minerva, contains the celebrated Christ of Michael Angelo, and in the church of St. Pietro *in Vincoli*, is the famous statue of Moses by the same artist. Many of the churches of Rome are adorned with fine paintings by the greatest masters, but their beauty and colouring has generally suffered much from time, neglect, dirt, and damp. In the church of Santa Maria della Pace are the four Sibyls of Raphael, and the church of the Augustines contains his inimitable fresco of Isaiah. A number of admirable paintings in fresco by Domenichino adorn a chapel in the church of San Liugi de Francesi. The church of the Capuchins possesses Guido's celebrated painting of the archangel Michael trampling upon Satan. Domenichino's ecstacy of St. Francis and a fresco of Giotto representing St. Peter walking upon the waves, also adorn this church. Daniel da Volterra's deposition from the cross, which Nicholas Poussin pronounced to be the third picture in the world, once enriched the church of the S. S. Trinità de Monti, but it was totally destroyed by the French in their clumsy attempt to remove it. Here is the tomb of Claud Lorraine, and his house stands beside the church; on the opposite side of the way is the house of Nicholas Poussin, and close by it a house once inhabited by Salvator Rosa. The church of San Andrea della Valle is built upon the spot where the curia of Pompey once stood, in which Cæsar fell. It contains some fine paintings in fresco by Domenichino. In the church of Sant' Onofrio the remains of Tasso repose. A number of the churches have been formed out of heathen temples, and it is curious to observe the striking resemblance which the modern Catholic churches bear to the ancient pagan temples in their plan and decoration, pictures, statues, worship of images, holy places, altars, and votive offerings, multiplied ceremonies, and pompous processions.[1]

There are in Rome

54 parishes, and 300 churches,
154 churches served by secular clergy,
130 ———— by regular clergy (monks,)
64 monasteries and convents for men,
50 ———————— for women.[2]

Nothing strikes a stranger with more admiration on his arrival in Rome than the immense number of fountains which pour forth on every side an inexhaustible supply of the finest water. They shew a great variety in their composition. Some of them are beautiful, one or two grand, but they are all, generally speaking, deficient in simplicity, and several of them, such as the renowned fountain of Trevi, are completely overloaded with mythological sculpture. The water of this fountain, which is the chief supply of modern Rome, is the delicious Aqua Vergine, the same that flowed into Rome in the age of Augustus.

Streets.

The streets of Rome are narrow, crooked, badly lighted, and dirty. The best street is the Corso, so named from being used for the course or promenade of carriages at the Carnival. Part of it is the ancient via lata, the rest follows the line of the Via Triumphalis. It is almost the only street that has the merit of being straight, and that can boast of *trottoirs* for foot passengers. It extends a mile in length, but is scarcely fifty feet in breadth. This, and all the other parts of the city, consist of buildings from three to five stories in height, built of stone, and plastered over. Every considerable tenement has a bust or portrait of the Virgin stuck upon one corner of it, at the second story, with a lamp in front at night, and an ornamental plaster moulding round it, into which are generally wrought some figures of angels or saints. Rome has no squares, and of the piazzas, the Piazzo del Popolo, and that in front of St. Peter's, are the only two that deserve notice. Both are adorned with obelisks, statues, and fountains. Gas light is unknown in Rome, and the lamps attached to the shrines of the Virgin were the only street lights until the French came and introduced the "reverberés" used in Paris. Rome contains 500 streets, 275 lanes, 148 places, and 5500 shops.

Rome has about 335 palaces, or noblemen's houses. Of these, about fifty or sixty are of a superior kind, uniting in their external appearance something of the fortress, the prison, and the palace. Many of the families to which these buildings once belonged have sunk into poverty, and their residences are now turned into ecclesiastical colleges or hotels, or let to foreign ambassadors or consuls. In the others which have escaped this fate, the lower storey is sometimes let for shops, sometimes retained for stables, coach-houses, and servant's rooms. The second storey is generally a picture gallery, consisting of a suite of rooms all opening into one another, and richly adorned with marble columns and painted ceilings. The owner of the building and of these precious works of art, lives in the third or highest story, and generously throws open the gallery to artists and to all who choose to give two or three paoli to the servants. The exterior of these palaces is lamentably destitute of architectural beauty, and in the interior, notwithstanding the magnitude of the apartments, and the magnificence of the decorations, they are, generally speaking, exceedingly incommodious and uncomfortable dwellings, and all of them are deficient in cleanliness and order. It is no uncommon thing for an Italian nobleman to reside in the attics of his own palace, and to let the principal apartments to lodgers. Over the gates of the palace are the escutcheons of the family, and as if in mockery, the initials S. P. Q. R. (Senatus Populusque Romanus.) The immense palaces of the Doria, the Colonna, and the Borghese, are still occupied only by their own families and dependants. The Doria palace contains the largest collection of paintings in Rome, among which are found some of the finest specimens of the ancient masters. The princely house of Colonna has produced more illustrious men, and can boast a nobler descent, than any in Rome. The gallery of their palace, which is by far the grandest in the city, once contained a number of celebrated paintings, but the finest have been sold. The palace garden, which hangs on the steep side of the Quirinal hill, contains the picturesque remains of a magnificent ancient edifice, the name of which is unknown. The palace of the Barberini family formerly contained that celebrated museum of ancient sculpture, vases, gems, medals, &c., which was so long the wonder and admiration of Europe, but it is now sold and dispersed. The famous Portland vase was brought from this museum. The palace of the Borghese once contained a fine museum of sculpture, and it still possesses the best collection of paintings in Rome. In the Palazzo Massimi is the famous Discobalus, the finest in the world, found in the grounds of the Villa Palombari on the Esquiline hill. The Palazzo Spada contains the celebrated statue of Pompey, at the foot of which Cæsar fell. In the palace of the Braschi stands the beautiful colossal statue of Antinous, which was dug up on the site of the ancient Gabii.

[2] Melchiori's Guide Methodique de Rome.

Statistics of Rome.

The palace of Lucien Bonaparte possesses a small collection, but entirely composed of masterpieces, and kept in beautiful preservation. The Palazzo Nuovo di Torlonia, the residence of Torlonia the Roman banker, who has purchased the title and estate of the Duca di Bracciano, is fitted up with all the magnificence that wealth can command. The gallery is adorned with Canova's colossal group of Hercules and Lychas. The Farnese palace contains the far-famed gallery painted in fresco by Annibal Caracci.

The Vati- an.

The Vatican has long been celebrated for its unrivalled splendour and magnificence. Its ceilings richly painted in fresco; its pictured pavements of ancient mosaic; its magnificent gates of bronze; its polished columns of ancient porphyry, the splendid spoils of the ruins of imperial Rome; its endless accumulation of Grecian marble, Egyptian granites, and Oriental alabasters; its bewildering extent and prodigality of magnificence; but, above all, its amazing treasures of sculpture, far surpass even the gorgeous dreams of Eastern magnificence.[1] In common with all the other collections of the fine arts in Rome, the Vatican suffered materially from the rapacity of the French, but on the downfall of Bonaparte the stolen treasures were restored to their rightful owners. The Vatican contains a museum filled with the most splendid specimens of ancient sculpture;—the tapestry chambers hung with tapestry woven in the looms of Flanders, and copied from the cartoons of Raphael;—a picture gallery, filled with the masterpieces of painting;—the *Camere* and *Loggie* of Raphael, painted in fresco by himself and his pupils;—the Sistina and Paolina chapels, painted in fresco by Michael Angelo;—and the library, the halls and galleries of which alone are more than thirteen hundred feet in length. The view from the balcony in front of the windows gave the name of *Belvidere* to the museum, and in consequence to the matchless statue of Apollo Belvidere, pronounced by universal consent to be the finest statue in the world. It was found near Antium, in the ruins of a Roman villa, supposed to have originally belonged to Nero. The name of its artist is unknown. Here, also, is the celebrated group of the Laocoon, which Pliny states to have been executed by Agesander the Rhodian, and Athenodorus and Polidorus, who are believed to have been his sons.[2] This wonderful masterpiece was found in the palace of Titus, on the very spot where it is described by Pliny to have stood, and every successive generation that has passed since it was formed, has gazed with admiration on its matchless sublimity. The Vatican also contains the two finest paintings in the world, the Transfiguration by Raphael, and Domenichino's Communion of St. Jerome. The library contains a splendid collection of books, and is peculiarly rich in rare and valuable manuscripts. But a minute account of the immense treasures of art accumulated in this magnificent building would occupy too much of our space.

Another of the Pope's palaces, the Lateran, has been converted into an hospital.

Iuseum of e Capitol.

The museum of the Capitol contains a very extensive collection of specimens of ancient sculpture. The finest works in it are the famous statue called the Dying Gladiator, found at Antium in the same spot with the Apollo Belvidere and the Fighting Gladiator; the two Furietti Centaurs; the old shrivelled crone, which some have called the Præfica, others a Sybil, others Hecuba; the group of Cupid and Psyche; Cupid bending his bow; the Osiris and Isis; the professor of the gymnastic art; the noble seated statue of Agrippina, the wife of Germanicus; the Camillus; the child playing with a swan; the bronze urn which bears the name of Mithridates; the four doves, a mosaic, which must be either the original or a copy of the famous mosaic of Sosus, in the temple of Pergamus, described by Pliny; and the bas-reliefs of the dispute between Agamemnon and Achilles; the Nine Muses; and the battle of the Amazons.[3] The Capitol contains also a museum of painting, but it is of very inferior interest.

The academy of St. Luke, in the Forum, contains Raphael's famous picture of St. Luke painting the Virgin's portrait. Here is preserved the skull of Raphael under a glass case.

Rome contains eleven public libraries, some of which are excellent. In the Augustine convent there is one containing upwards of one hundred thousand volumes, which is open to the public.

Villas.

There are a great many villas in the immediate vicinity of Rome, and even within its walls. Every villa has at least one building, called a casino, containing a suite of entertaining rooms, fitted up with all the luxury of painting and sculpture. The villa and garden of the Borghese, which are by far the most beautiful pleasure grounds at Rome, are open as a common drive to the whole metropolis. The villa Ludovisi, within the walls of the city, is nearly two miles in circuit. It contains an invaluable collection of celebrated pieces of ancient statuary, of which no copies are known to exist. The magnificent villa Medici, on the Pincian hill, is now converted into the French academy, where a number of young artists of promise are supported at the charge of the French government, with the view of enabling them to enjoy the advantages of a few years study at Rome. The villa Albani is enriched with the most precious collection of ancient sculpture that any private cabinet ever contained. The finest specimens of this collection are the famous Apollo *Sauroctonos*, the most beautiful bronze statue now left in the world, and which, in the judgment of Winkelman, is the original of Praxiteles, described by Pliny; the statue of Minerva, which is pronounced by Winkelman to be the only monument now existing at Rome of the sublime age of art that lasted from the age of Phidias to that of Praxiteles; and the far-famed relievo of Antinous, which, says Winkelman, "after the Apollo and the Laocoon, is perhaps the most beautiful monument of antiquity which time has transmitted to us."[4]

Castle of St. Angelo

The castle of St. Angelo, "the mole which Hadrian rear'd on high," was originally called "Moles Adriani," from the name of its founder, who destined it to hold his remains for ever. It is a circular building, and was formerly reckoned very strong; it has stood many sieges, but as a fortress it is wholly untenable against modern tactics. It has been so often taken and retaken, repaired and altered, that but little of the original structure now remains, except the walls. It communicates with the Vatican by a long covered gallery, made by Pope Alexander VI., to afford him a way of escape from the just fury of his subjects. The castle of St. Angelo is now used as a place of confinement for prisoners sentenced to the galleys. The upper part of it also serves as a state prison for criminals of rank, and those who fall under the suspicion and displeasure of the Pope.

Population

The population of Rome, which in 1800 amounted to 153,004, gradually diminished till it was only 117,882 in 1813. Since that period, however, it has progressively increased, and in 1836 consisted of 153,678, exclusive of Jews, who amount to 3700. On the dismemberment of the Pontifical territory in 1800, the population of those parts which now form the government was 2,400,000, in 1829 that population had increased to 2,679,524, being an augmentation of about one-eighth.

The population returns for the city of Rome in 1836, are thus given by the authorities:—

Productions.

The principal productions of the country are corn, such as wheat and maize, vegetables, rice, hemp, wines, vinegar, brandy, tartar, wine lees, oil, timber, charcoal, tobacco. The produce of secondary importance is fruit, potatoes, flax, seeds, and oleaginous vegetables, dye-woods, and barks of the cork and other trees, potash, soda, hay, mulberry-trees, aniseed, &c. The main agricultural products are cattle, both large and small, with their secondary productions, such as wool, cheese, butter, hides, bacon, &c.; silks, wax, honey, tallow, horns and bones, parchment, &c. Buffalos, goats, mules, and other animals for carriage, are found, but not in large numbers. Domestic fowls, and game of all sorts, are in abundance.

The cultivation of rice, vegetables, potatoes, hemp, olives, mulberry-trees, silk worms, horned cattle and sheep, with cheese and wool, is on the increase, while, on the contrary, corn, firewood, charcoal, wood, pine-kernels, horses, and the salted sardinias of the Adriatic are diminishing. The fishing-trade generally is declining or almost extinct. Other produce is nearly stationary.

Statis of Ron

With respect to the mineral productions of the Pontifical States, but little information can be given. They possess excellent earths, argillaceous and others, fit for various manufactures, and especially for earthenware. Pozzolano is found at Rome and elsewhere; travertine, peperine, and other building stones, at Tivoli, Albano, &c. Millstones, siliceous and fire-stones, fuller's earth, alabaster, are also found. In some parts are marbles, variegated and sculptuary. Rock crystals are found at Tolfa, and elsewhere. They produce also salts and bitumens, alum, vitriol, fossil coal, pitch and naphtha. They have no fossil, but abundance of marine salt, the annual produce of which is 76,000,000 lbs. There are many salt-springs in Romagna and the frontiers, and abundance of salubrious mineral springs, both hot and cold. Of metals there are indices of gold and silver in various places, but the quantities are small. Iron ore is believed to exist in the territory of Terni, Viterbo, Bologna, and elsewhere, but no sufficient trial has been made to enable a correct estimate to be formed of the probable produce. Copper ores, quicksilver, marcasite and lead, have also been found. Pozzolana is employed for subaquatic works, and is exported to some extent. The Viterbo vitriol mines produce more than 100,000 lbs., one-half of which is exported. There are many mines of fossil coal, which were worked with great success, and the coal was found most abundant and excellent, but they have of late been utterly neglected. About four million lbs. of sulphur are dug in Romagna, Pesaro, and Tormignano. The government works only the alum mines, all the rest are private undertakings.

Agricult

Roman agriculture is by no means in a flourishing state. Most of the lands in the Agro Romano, and generally in the Maremme, extending from the confines of Tuscany to those of Naples, are divided into large properties. The extent varies much, some containing no less than 8000 hectares, and others not exceeding a few hundred hectares; but, generally speaking, the landed properties vary from 500 to 1000 hectares. All the tract of country from the Apennines to the Mediterranean, with the exception of the suburban districts near the towns and villages, is divided into possessions of considerable size. But the number of wealthy proprietors is very small, perhaps there are not twenty landholders of ample fortune. The great majority of them are poor, a few of them are tolerably well off, but the opulent are rare indeed. The value of land is almost infinitely various; the rent in the Maremme varies from a half to four crowns per hectare. Beyond the Maremme it is sometimes let at twenty crowns per hectare (L.4) per annum, and in some cases the rental exceeds that sum. Lands do not ordinarily render more than two and a-half or three per cent. In the neighbourhood of the large towns of the State, land readily sells for forty years' purchase. The agricultural labourers are grossly ignorant, and they have no means of acquiring education, though they are neither indolent nor unwilling to better their condition. They in general live badly, using, for the most part, maize bread and *polenta*, beans and pulse, and other vegetables, but they seldom are able to obtain animal food. In winter their beverage is *picchetta*, a mixture of wine and water, and in summer wine alone. In the populous districts, wages vary from one to two pauls (5d. to 10d.) and in the Maremme from two to four pauls per day, according to the employment, the season, and the locality.

In the most populous and best cultivated districts, there is usually an annual change from spring grasses to corn produce, but in the Maremme the soil is often left to repose for from three to seven years. No operations on a large scale can be carried on there in summer, owing to the state of the climate. In the summer season, the animals are driven from the plains to the mountains, and after the gathering of the harvest, the Maremme are abandoned, on account of the malaria. The leases in these districts are sometimes subset to smaller cultivators, and even subdivided into small fractions. But in other parts of the country leases are rarely granted; land is almost all colonized, that is, farmed on the mezzeria principle, a system which is productive of the worst results. The general arrangement is, that the landowner shall receive from the coloni half the produce of the soil; but there are many cases in which the amount received is not one-sixth of the produce. The coloni are generally in debt to their landlords, and are often in a state of insolvency.

---

[1] The Tavola censuale = 1,000 square metres; so that 39,985,235 T. ◻ C. = 11,632,745 miles ◻ Italian, of 60 to the degree.

The Roman states produce a supply of cattle sufficient for the ordinary consumption. Horses are exported, and there is a small importation of oxen and swine. The breed of sheep is improving, and the export of wool is considerable, and is rapidly increasing. Olive plantations were long one of the most productive investments; but they are now less so than the cultivation of the white mulberry, which would spread widely were capital abundant. Vineyards have been too extensively planted, and now yield no return equivalent to the outlay. The culture of the wheat has diminished solely from the absence of external demand, and the consequent decline of prices. The instruments of husbandry employed are of the rudest kind. The heavy customs have prevented the introduction of improved implements, and the arts are too little advanced to allow their production at home. The principal impediments in the Roman states to agricultural improvements are, the political situation of the country; the protecting system, which keeps all the producing powers in backwardness; the want of capital; the want of population in the Maremme, and the mezzeria system elsewhere; the want of knowledge, and more especially of agricultural knowledge; the extreme difficulty proprietors have in finding managers for their estates who are able and willing to introduce the improvements that have been adopted elsewhere; mortmain, the heavy burden of taxation falling particularly on proprietors, agriculturists, and their productions, and the difficulty of sales from restricted relations.[1]

The population of the Roman states in general is rather agricultural than manufacturing, and their manufactures serve only for the home consumption. There is little demand for them abroad. The papal government has made enormous sacrifices, by protections, prohibitions, and premiums, for the encouragement of what is called native industry; but these measures, so far from increasing and improving manufacturing produce, have been the main causes of decline and decay. Their only effect has been to reward and to render permanent the most rude and ignorant processes of manufacture. Scarcely a valuable discovery has been introduced into their manufactories, and the looms are still such as were generally employed in the fourteenth century. Many a town in Great Britain, consisting only of 30,000 souls, produces a greater quantity of manufactured articles than the three million inhabitants of the pontifical states. The principal manufacture is that of woollens of ordinary quality. Rome is the chief seat of this manufacture, and the value of the fabrics produced annually, is calculated at 300,000 crowns, (L.60,000.) Next to woollens stands the manufacture of hats. They are well made every where, but especially at Rome, and to the amount of 200,000 crowns, (L.40,000.) There are silk manufactories in Rome, Bologna, Camerino, and Brugia; but the trade is declining. Next in importance to woollen and silk manufactories, are those of tanned and dressed leather. Gloves are made in Rome and Bologna, to the extent of from 90,000 to 100,000 pairs annually. Roman musical strings enjoy a very ancient and deserved reputation. The annual quantity made amounts in value to 10,000 crowns. There are scarcely any manufactories of cotton goods. The government has made great sacrifices to maintain an establishment at the Diocletian baths, but without success. The fabrics of hemp and flax are more numerous than those of cotton, but there are no factories; all the goods produced are manufactured either in public schools, orphan asylums, or private houses. The other articles of manufacture are ropes and cordage, wax and tallow candles, paper, cream of tartar, liquorice juice, pig iron, copper manufactures, earthenware, and glass. An extensive trade was formerly carried on in alum, which was dug in large quantities in the mountains of Tolfa, but the introduction of artificial alum, by lowering the prices, has greatly diminished this trade. Raw sulphur is found in large quantities and of excellent quality. After supplying the home consumption, both raw and refined sulphur are exported to the amount of four million lbs. giving an annual proceed of 120,000 crowns. The sulphuric manufactures of Bologna produce annually 50,000 lbs. of sulphuric, and 10,000 lbs. of nitric acid.

Trade.

The trade of the Roman states is far from extensive or flourishing. The principal exports are corn from Romagna and the frontier districts; but this trade is diminishing. Sheep 50,000 yearly, swine 40,000, oxen 10,000. The export to England of Roman wool is become very considerable, and is increasing rapidly. The provinces on the west of the Apennines export from 800,000 to 900,000 lbs. of wool for Piedmont and France. A million lbs. of cheese go to Tuscany and Sardinia; of lambs skins, about 400,000 lbs. are shipped to England, Piedmont, and Naples. Of horns and bones, there is an export of 15,000 lbs.; of honey, 10,000 lbs.; of skins, 100,000 lbs.; of tallow, 200,000 lbs.; of lard and fat, 150,000 lbs.; of hemp, 30 millions of lbs.; of white and brown rags, 3 millions lbs.; of oil, 1 million lbs.; of tobacco, 300,000 lbs., but the government monopoly is a great impediment to the extended cultivation of a plant to which the soil is well adapted. There is a large export of planks to Spain, America, and France, besides other articles.

Imports.

The imports are to some extent affected by the circumstance, that a chain of mountains traverses the country, making the north-west almost inaccessible to the south, so that while one part of the state is exporting, another is importing the same article. Colonial produce is received principally from England and France; and the consumption is, of raw sugar, 10,000,000 lbs.; coffee, 1,600,000 lbs.; pepper, 1,000,000 lbs.; cocoa, 50,000 lbs.; cinnamon, 40,000 lbs.; cloves, 35,000 lbs.; and raw cotton, 150,000 lbs. Of other principal articles, the yearly imports are, from 40,000 to 50,000 sheep; from 12,000 to 13,000 calves or oxen; 8000 to 9000 swine; 16,000 to 18,000 cows; some costly horses, principally for the capital; hides, about 1,200,000 lbs.; raw skins, 50,000 lbs.; coarse wool for mattresses, 1,000,000 lbs.; cheese, 1,300,000 lbs.; butter, 70,000 lbs.; wax, 700,000 lbs.; cochineal and kernes, salt fish from England, 8,700,000 lbs.; about 3,000,000 lbs. more of pilchards, Sardinian salmon, &c. are brought from Spain, France, Sicily, and Russia.

The tariff which regulates the import and export duties of the Pontifical states, is dated 28th April 1830.[2]

The prohibitions in the Roman states are not numerous. On imports they include the articles farmed, as salt, tobacco, alum, vitriol, playing cards, pictures, engravings, &c.

---

[1] See the communication of one of the largest landed proprietors in the Roman States, in Dr. Bowring's Report, &c. p. 78, 79.

[2] Report on the Statistics of the Roman States, by Dr. Bowring. 1837.

The Corn-Laws in the Roman States are as follows.

Mediterranean.	Adriatic.	Duties.	
		Import.	Export.
Wheat, when the price is Under 14 crowns	Under 12 crowns, per 640 lbs.	Prohibited.	Free.
up to 14 ...	Up to 12	Crowns 2	1
up to 15 ...	Up to 13	... 1	2
up to 16 ...	Up to 14	No duty.	Prohibited.
Flour, under 16 ...	Under 14	Prohibited.	Free.
up to 16 ...	Up to 14	Crowns 1 50	75
up to 17 ...	Up to 15	... 75	1 50
up to 18 ...	Up to 16	Free.	Prohibited.

A similar legislation is applied to bread, maize, beans, peas, potatoes, and chesnuts; but rice is subject to an export duty of one bajocco per 100 lbs.

The exports to England are few, and consist mainly of grain, raw hemp, rags, raw and refined sulphur, silk, cream of tartar, wood, lamb and kid skins, cork, &c. English vessels load goods at Civita Vecchia, but the major part of the above articles are shipped for England from Leghorn, Genoa, and Marseilles.

Rome receives from England colonial produce, fish, medicines, drugs, and dye-stuffs, metals, cotton-twist, piece goods of all sorts, hardware, and iron and steel goods, jewellery, glass, earthenware, porcelain, &c.

Roads. The roads of the Pontifical states are, generally speaking, well kept. They are best at a distance from the capital, and worst in its immediate neighbourhood, from the want of siliceous material for repairs. Ever from the time of the ancient Romans, the roads have been divided into the three classes of consular, provincial, and communal. By a decree of the 23d October 1817, this arrangement was regulated, and a board nominated to the charge of the roads; and it was determined to levy a tenth part of the praedial impost for the consular roads, a variable quota from the provinces for the provincial roads, and another at the charge of the municipalities for the communal roads.

The bankers Torlonia recently proposed a scheme of great utility, that of introducing steam navigation on the Tiber, establishing a port on its mouth, extending steam communication from it to Naples, Leghorn, and all the adjoining coast. But after the steam vessels and omnibuses were contracted for, and nearly ready, the government took alarm, and put an interdict on the scheme. In the stage coaches travellers pay 35 bajocchi per post, (somewhat less than 2d. per mile, English). Money, jewels, and effects of small bulk and large value, are conveyed from one end to the other of the Roman states, if under 100 crowns, at 2 per cent; from 100 to 500 at 1 per cent, &c. The government messengers have the privilege of conveying travellers for their own account, and their general charge is 60 bajocchi per post, (somewhat more than 3d. per mile), half of which they are required to pay to government. The price of travelling in ordinary vehicles averages at from 3 to 3½ crowns per 100 miles per individual, comprising one meal to be furnished by the *vetturino*. By carriage or carts the general charge for the carriage of goods is 1 crown per 100 miles.

Wages. Wages in the Roman states are low; and in general it may be stated, that the services which in England cost a shilling, in France a franc, in the Papal states cost a paul, (54 centimes, or about 5½d. sterling). A day's labour in summer costs 30 bajocchi, (14d. sterling), but in winter only 15 to 20 bajocchi, (7d. to 10d. sterling); and the prices of the ordinary articles of consumption vary much in the different parts of the Roman states. There is a very great difference between those in the capital and those on the two sides of the Apennines. The rate of wages paid in town and country are as follows:—

In town, a	valet	10	crowns per month, lodging and food.
	waiting-maid	6	ditto, ditto.
	footman	8	ditto, and clothing.
	maid-servant	2	ditto, lodging and clothing.
	wardrobe-keeper	4	ditto, ditto.
	coachman	10	ditto, and clothing.
	rider	7. 50	ditto, ditto.
	groom	6	ditto, ditto.
	cook	10	ditto, lodging and food.
	boy	3	ditto, and food.
In country,	labourer	6	ditto, lodgings and food.
	shepherd	4	ditto, ditto.
	boy	3	ditto, ditto.

The monthly expenses of maintaining a family in the country, composed of six individuals, are, (including rent,) 17 crowns, 10 bajs., making 2·85 crowns per person, without calculating medical charges, so that, according to the above estimate, a family of six person living in the country can subsist on 17s. a-week, or about L.41 per annum. But in Rome, the monthly expenses of a family of the middling classes, composed of six individuals, would be 52 crowns, 33; that is to say, 8·72 per individual, about L.2, 12s. 6d. per week, or about L.125 a-year, for the expenditure of a family of the trading classes.

Prices of ordinary articles of consumption in the markets of Rome.

Bread	Bajocchi 2½	per lb. of 12 oz.	
Flesh-meat	6½	”	
Fish	6	”	
Flour	3	”	
Salt	3	”	
Hogs' lard	9	”	
Salt meat	12	”	
Vegetables	2½	”	
Wine	10	per bocale.	2½ bocali equal to 1 gallon.
Oil	40	”	

Wages paid for different classes of labour:—

Masons	Pauls per diem 4½
Carpenters	6
Blacksmiths	6
House Painters	6
Stonemasons	6
Workers in stucco	6
Upholsterers	4
Coachmakers	6
Sawyers	5
Potters	4
Dyers	5
Spinners	6
Weavers	5½
Printers	Pauls per diem 5
Millers	3
Bakers	8
Waiter at public-houses	3½
Goldsmiths	5
Watchmakers	4
Tailors	5
Milliners	2
Shoemakers	5
Hatters	6
Agriculturists of various classes	3½

Statistics of Rome.

Civil government.

The civil government is in the hands of the College of Cardinals, and the executive is administered by the Cardinal Vicarius, who is a kind of prime minister. It has been defined to be "a government administered by monks, who conduct the affairs of a nation by the rules of a convent, and apply the maxims of the twelfth century to the business of the nineteenth;" and the apathy and timidity, the dread of independent thinking and of free inquiry which it manifests, fully justify the statement. Such is the dread of innovation, that even vaccination is not permitted in Rome. The press is held in rigid durance, and all the best works on mental philosophy are prohibited. As might have been expected, these restrictions have proved in the highest degree injurious to the prosperity of literature. The state of science in Rome is still less flourishing, for it has been the constant policy of the papal government from the days of Galileo to the present time, to discourage as much as possible the research after truth. Rome, therefore, has not one eminent man of science; there are very few who take even any interest in the matter; nor is there a single museum of natural history, public or private, worth notice. The constitution of society, too, is so framed as to hold every man in the situation in which he is born. However meritorious or enterprising he may be, he can scarcely ever expect by his own personal exertion to raise himself to a higher station, for there are barriers he can never pass.

The clergy constitute the nobility of Rome; they form the court of the sovereign, and fill all civil offices as well as ecclesiastical. The persons styled Roman princes are few in number, and, with two or three exceptions, very poor, and totally destitute of power or authority.

Religion.

The inhabitants of the papal states, with very few exceptions, profess the Romish faith. According to the official returns the number of Jews in Rome is 3700; of heretics and Turks, 201. The Jews are compelled to reside in one particular quarter of the city. There is now a Protestant place of worship in Rome, in which an English clergyman regularly officiates, but this is rather connived at than openly tolerated. Of late years there has been a considerable increase in the number of the clergy. In 1825 they amounted to 4938; in 1835, to 5273. According to the official statement, there were, in 1836, 37 bishops, 1468 priests, 2023 monks, 1384 nuns, and in houses of education, 698. There is thus in Rome one clergyman for every ten families; but it is supposed that the real number considerably exceeds the official return. The state of morals, both among clergy and laity, is far from satisfactory.

Statistics of Rome.

Education.

The absence of statistical accounts makes it impossible to state what is the number of children in the schools of the Roman territory. According to the calculation of the government, it is about 1 in 50 of the population. A bull was issued on this subject by Pope Leo XII., which was followed by a "Reglamento degli Studj," erecting a board intended to have the general direction of the business of education, the control of all universities and schools, and consists of certain cardinals in official stations, and others, to be nominated by the pope. It established two primary universities, Rome and Bologna, and six secondary universities. The universities have four faculties, theology, law, medico-surgery, and philosophy. But of this Reglamento only a very small portion refers to public schools. They are placed almost entirely under the control of the bishop. The teachers are elected by the communal council, but the bishop must confirm the nomination, and he possesses a perpetual power of dismissal without reference to the local authorities. But the business of education is almost universally neglected. The elementary schools in Rome are 872; the number of masters, 482, and of scholars, 14,099; that is to say, in the infant schools, 4800; in the gratuitous elementary schools for boys, 2694; for girls, 287; in the schools where a small sum is paid for instruction, 2115 boys, and 1600 girls. Many parts of Rome, however, as Trastavere and the Borgo, are very ill supplied. Rome contains four ecclesiastical boarding-schools, two seminaries, seven ecclesiastical colleges, five secular colleges, two universities, nine gratuitous parish schools, and sixty regionary; seven schools kept by monks, one for the deaf and dumb, five pious places of education for males, and fourteen for females.

Two banks for savings have lately been established, one in Rome, the other in Spoleto; that of Rome has been very successful, and in six months has received 50,000 crowns in deposits. The Monte di Pietà of Rome has existed for nearly three centuries. It has passed through many vicissitudes, and has now a circulating capital of about 230,000 crowns advanced on about 200,000 pledges. It is proposed to associate this establishment with the savings bank, which is now attached to the lottery office.

The following Table shews the Receipts and Expenditure of the Roman States.

General Heads of Receipt.			Expenses of Administration.			State Expenses.		
No.	Particular Heads.	Crowns.	No.	Particular Heads.	Crowns.	No.	Heads.	Crowns.
1	Predial imposts, landed property, &c.	3,280,000 00	1	Predial imposts, landed property, &c.	760,000 00	1	Sacred palaces, sacred college, ecclesiastical congregations, and diplomatic body abroad	500,000 00
2	Monopolies, customs, and taxes on consumption	4,120,000 00	2	Monopolies, customs, and taxes on consumption	460,000 00	2	Public debt	2,680,000 00
3	Stamps and registries	550,000 00	3	Stamps and registries	90,000 00	3	Expenses of state government	530,000 00
4	Post-office	250,000 00	4	Post-office	150,000 00	4	Justice and police	920,000,00
5	Lotteries	1,100,000 00	5	Lotteries	760,000 00	5	Public instruction, fine arts, and commerce	110,000 00
	Total of receipts	9,300,000 00		Total administration and charges	2,220,000 00	6	Charities and acts of public beneficence	280,000 00
	Deduct	2,220,000 00				7	Public works, cleaning and illuminating Rome	580,000 00
		7,080,000 00				8	Troops of the line and carabineers	1,900,000 00
						9	Other military charges, health, and marine	290,000 00
						10	Public festivals, aud extra expenses	44,000 00
						11	Reserve fund	100,000 00
							Total of expenses of the state	7,934,000 00

evenue.

Thus the net receipts exhibit 7,080,000 crowns, and the net expenditure 7,934,000 crowns, showing a deficit of 854,000 crowns.

The average cost of collection appears to be nearly one-fourth of the gross revenue. That of the predial imposts, 23 per cent.; of the customs. &c., 11 per cent.; stamps,

Statistics of Rome.

&c., 16 per cent.; post-office, 60 per cent.; lotteries, 69 per cent. The interest on the national debt absorbs about 38 per cent. of the net revenue.

Taxation.

If the population of the Roman states be estimated at 2,800,000, and the average expenditure at 9,000,000 crowns, the amount of taxation per individual would be about 12s. 10d. per annum.

The principal taxes levied are,—

1. Tax on consumption (exclusive of that on flour) which, if estimated on the whole of the male population above the the age of 16, would give 60 bajocchi per head, (2s. 6d. sterling.)

2. The personal tax which is levied according to the classification of the payers, with a reference to their wealth. If averaged upon the males above 16 years, its amount would be 40 bajocchi each, (1s. 7d. sterling.)

3. Additional impost on the value of the cadastral survey.

4. Various taxes of localities, markets, offices, &c., as on weights and measures; on fishing and hunting, &c.

Army.

The papal troops consist of

Polizia	4000
Custom-house officers	1500
Armed functionaries	5500
Artillery	1000
Cavalry	1000
Infantry	12000
Regulars	14000

And about 15,000 militia, who are not in active service.

Charitable institutions

It is a boast of the Romans that in no city is so large a sum devoted to public charity in proportion to the population. The proportional payments of Rome for charitable purposes are about double those of Paris. Rome has a yearly revenue from charitable funds of 1,900,000 francs; and the state grants annually 2,200,000, making a yearly revenue of 4,100,000 francs. But of the immense number of benevolent establishments in Rome, a great proportion are of doubtful, ill-directed, and even pernicious charity; and in spite of the liberality with which money is scattered, nowhere is more mendicity, wretchedness, idleness, and want.

Hospitals

Besides the foundling hospitals, which are very numerous, there are thirteen societies for giving dowries to girls on their marrying, and pecuniary gifts on their taking the veil. Of 1400 women who are married at Rome annually, no less than 1000 receive dowries from the public purse, the annual payment for this object being 32,000 crowns, or L.8000 sterling. Independently of public institutions, there is much private almsgiving. There are in Rome twenty-two establishments for the diseased, the insane, and the convalescent, of which eight are public, eleven are private hospitals, two are institutions for visiting the sick in their houses, and one is for the burial of the dead. These hospitals can accommodate about 4000 persons. The maximum of deaths is 11.60 per cent. the minimum 5.43. The average cost of ordinary patients is two pauls per day, (10d.)

Rome is one of the great recipients for abandoned children, which are brought thither from remote provinces, and even from the kingdom of Naples. In St. Spirito 800 boys are annually received; the Conservatory receives ordinarily 800 girls; five other hospitals have 544 boys and 670 girls. At the end of 1838, there were 1672 children in the St. Spirito asylum; 804 were deposited in that year, 684 had departed, and 1552 remained from the former year. No less than 580 children died in the year, being a mortality of 72 per cent.

Justice.

The latest official document respecting the administration of justice is that of 1832 The number of condemned persons in that year was 2708, but about 8000 more must be added to these for criminals already in prison, so that the number of prisoners is generally about 6000. Criminal proceedings in the Papal States are very dilatory. The prisons receive all offenders, whether of correctional or criminal police; and as there is no liberation of the accused on bail, there is necessarily a considerable aggregation of offenders. (B. Q.)

Statement of the Criminals in the different places of Detention, with the Classification of their Crimes and Punishment in December 1832.

No.	Places of Punishment.	Will hold.	Number of Criminals actually detained.	Length of Punishment.					NATURE OF OFFENCES.															Total.

Burgess's *Antiquities of Rome; Rome in the Nineteenth Century;* Eustace's *Classical Tour;* Forsyth's *Italy;* Melchiorri, *Guide Methodique de Rome;* Dr. Bowring's *Report of the Statistics of the Pontifical States.*

ROMILLY, Samuel, one of the most enlightened and virtuous public men whom England has ever possessed, was, as his family-name indicates, the descendant of a French family. He was the son of a jeweller in London, and was born there on the 1st of March 1757.

The education of this child, destined in time to occupy so distinguished a place, was conducted for some time with even less care than might have been expected from the station held by his family. But, heartily disliking his father's business, he was at length allowed to change it for professional employments, though as yet in an inferior department. At the age of sixteen he was articled to one of the six clerks in chancery; and in the easy mechanical duties of his master's chambers, relieved by the zealous prosecution of his studies both in English and Latin, passed several years of his life. He then resolved on coming to the bar, a step which, he informs us, all his friends, with one exception, considered as highly imprudent. One circumstance which helped to determine Romilly was very interesting; the purchase of a seat in the office in which he had been articled would have cost a sum which he knew it would be inconvenient for his father to advance.

He had completed his twenty-first year when he entered himself at Gray's Inn, becoming, at the same time, a pupil of an able equity-draftsman. General reading both in English and Latin, translation habitually practised from the latter language into the former, the composition of a few political essays for the newspapers, and occasional attendance on the houses of parliament, now alternated with a closeness of application to legal study, which, after a time, injured his health, and compelled him to retire, first to Bath, and afterwards to the continent. At Geneva he became acquainted with some of the men who were then beginning to attract notice in that city; and, among acquaintances thus made, the most valuable was that of Dumont. After visiting some of the nearest scenery of the Leman Lake, and of Savoy, Romilly proceeded to Paris, where he met D'Alembert, Diderot, and other eminent men.

On the last day of Easter term 1783, he was called to the bar. For some years afterwards, he obtained an increasing employment in the drawing of chancery pleadings; but during this time, as he says himself, he had hardly once occasion to open his lips in court. In the spring of 1784, he went upon the midland circuit, which he continued to frequent until, even as admitted in his own modest Memoir, he was decidedly its leader. His chancery business, however, to which at length he entirely devoted himself, had become very great before he confined himself entirely to town; and his principal reason for remaining so long on the circuit, is assigned by himself in one of his calmly characteristic expressions of honourable ambition: he desired to qualify himself for being a *judge*.

Long before he left the circuit, he had attained a distinguished position in the eyes of those who were qualified to appreciate him, not merely as a lawyer, but as a statesman. In 1784, he became acquainted with Mirabeau, who was then in London, and of whose character he appears to have formed an exceedingly just estimate. Mirabeau was the medium through which Romilly became known to Lord Lansdowne, and thus to the leaders of that political party of which he had throughout been an honest and warm adherent. To that nobleman he was recommended, both by the hearty praises of Mirabeau, and by a pamphlet he had written, called "A Fragment on the Constitutional Power and Duties of Juries." Lord Lansdowne, directing Romilly's attention to a recent sanguinary tract on Criminal Punishments, induced him to write an answer, which was published anonymously, under the title of "Observations on a late Publication, entitled 'Thoughts on Executive Justice.'" In the mean time he continued vigorously to prosecute in private the inquiries into the Reform of the Laws, especially the Criminal Laws, of which he had thus begun to announce publicly the parts.

In the vacation of 1788, he paid a third visit to Paris. Introductions from England, and other circumstances, brought Romilly and his fellow-traveller Dumont into intercourse, upon this occasion, with many men distinguished then, and with others still more celebrated in the bloody struggle that was about to ensue. Mirabeau at this time translated into French, and published, observations made by Romilly on the Hospital and Prison of Bicêtre. This pamphlet had the honour to be suppressed by the police of Paris, but in the original English was afterwards printed by the author himself in an obscure London periodical. In July 1789, Romilly wrote a pamphlet which was afterwards published; "Thoughts on the Probable Influence of the French Revolution on Great Britain." But the lively interest he took in the events which emerged in Paris, while he was engaged in composing these remarks, led him back to that city in August of the same year; and he now saw, both in public and private, many of the persons who had become most distinguished in the National Assembly. Dumont's observations upon the eventful summer of 1789 in France, were translated into English by Romilly, and, with the addition of some observations by himself on England, were published in 1792, receiving the title of "Groenvelt's Letters." Many of Romilly's opinions on the progress of the French Revolution are contained in his published correspondence with Dumont, Madame Gautier, Dugald Stewart, and others, and in a diary which he kept during a journey to Paris in the autumn of 1802.

While Romilly was thus advancing to the highest rank in his profession, and had gained the confidence and admiration of some of the best statesmen in England, his domestic position underwent a most beneficial change, the immediate cause of which was a visit paid to Lord Lansdowne. In his private Memoirs he thus speaks of a person whom he accidentally met on this occasion. "I saw in her the most beautiful and accomplished creature that ever blessed the sight and understanding of man. A most intelligent mind, an uncommonly correct judgment, a lively imagination, a cheerful disposition, a noble and generous way of thinking, an elevation and heroism of character, and a warmth and tenderness of affection, such as is rarely found even in her sex, were among her extraordinary endowments. I was captivated alike by the beauties of her person and the charms of her mind. A mutual attachment was formed between us, which at the end of little more than a year was consecrated by marriage. All the happiness I have known in her beloved society, all the many and exquisite enjoyments which my dear children have afforded me, even my extraordinary success in my profession, the labours of which, if my life had not been so cheered and exhilarated, I never could have undergone,—all are to be traced to this trivial cause." The object of this beautiful eulogium was the eldest daughter of Mr Garbett of Knill Court in Herefordshire. His marriage with this lady took place in January 1798, when he had nearly completed his forty-first year.

He continued to be chiefly occupied in the discharge of his duties as a leader of the Chancery bar for several years, after which he united with these the other avocations that have given to his name so distinguished a place in the list of British statesmen. In the autumn of 1805 he had received from the Prince of Wales the offer of a seat in parliament, which he declined upon grounds strongly marking his sturdy independence of character. These reasons were the same which, many years before, had made him interfere to prevent a similar offer from being addressed to him by Lord Lansdowne. He said that, notwithstanding the declaration made, in both cases, of his being totally unfettered, yet he never could feel real independence while he thus held his place in the Commons by favour; and, he adds, "I formed to myself an unalterable resolution, *never*, unless I held a public office, to come into parliament but by a popular election, or by paying the common price for my seat. As to the first of these, I knew, of course, that I must never look for it; and as for the latter, I determined to wait till the labours of my profession should have enabled me to accomplish it without being guilty of any great extravagance." He was soon rewarded for the scrupulous feeling of honour which had thus forced him to decline a place, that held out to him, as he confesses, very strong temptations.

In February 1806, he was appointed Solicitor General under the government of Mr Fox and Lord Grenville, with neither of whom had he previously any connexion. He was obliged, much against his will, to accept the honour of knighthood, and was elected to represent the borough of Queenborough, accepting this seat, without scruple, from the government. "If I had come in," says he, "as a private individual, I would not have accepted a seat from any body; but as long as I hold the office to which I have been appointed, I must support the administration. As soon as they appear to me unworthy to be supported, it will be my duty to resign." Of the public life which commenced under these auspices, and was prematurely brought to a close in thirteen years, Sir Samuel Romilly kept a minute and faithful diary, the contents of which have lately been made known to the world. No existing record of a political career presents a purer picture than does this;—the history of a course of public conduct directed invariably by those qualities of mind and heart which we have, even in this hasty sketch, seen to have guided the earlier years spent in his family and in his profession. It is impossible to embrace, within these limits, so much as a catalogue of the parliamentary measures in which he took a share, in the way of inciting others to action, in the way of himself acting and speaking and writing in favour of reforms in the laws and constitution, in the way of resisting encroachments on public rights or on just economical principles. And if a selection were to be attempted of a few of his principal public acts, that selection could not be made without omitting many which, in particular views, might be considered more important than those that would be specified.

But the design which lay closest to Romilly's heart, and occupied most of the energies of his capacious intellect, was the amelioration of the law of England, especially in its criminal sections. For such plans his official duties, added to those of his profession and of his place in parliament, allowed him at first no leisure; but from some of these trammels he was speedily released, by the fall of the Whig ministry in March 1807. In the new parliament he was returned for Horsham, on the Duke of Norfolk's interest, engaging to pay L.2000 for his seat if he should be able to keep it in spite of a petition, which was expected to be presented in consequence of doubts entertained as to the qualification of many of the voters. The petition proved successful, and his next election was made on terms equally characteristic. A seat was offered him for Wareham, for which, although L.3000 were demanded, he was asked to pay but L.2000, the remaining L.1000 being promised from a fund subscribed for extraordinary purposes by the leaders of the opposition. Romilly peremptorily refused to be indebted even to the public men with whom he systematically acted. He accepted the seat, but paid the whole price himself.

He now occupied a very prominent position in parliament. The eyes of the most liberally organized constituencies in the country were directed towards him; and in 1811, when a dissolution was impending, it was proposed in several such places to put him up as a candidate. For Liverpool, which was one of these, he at once refused to stand, on account of the disturbances which the contest was sure to occasion. In regard to the county of Middlesex, a negotiation was attempted by Major Cartwright, which was frustrated by Sir Samuel's flatly refusing to give, before his nomination, a pledge in favour of annual parliaments, and of such reform as should make the suffrage co-extensive with the taxation. He however accepted a requisition from Bristol, but was defeated by a coalition between the Tories and a section of the Whigs. He then obtained a seat for Arundel, on the interest of the Duke of Norfolk, an assurance of perfect independence being given him by the patron, but no price being paid on this occasion. Romilly's justification of his change of views is very briefly stated in his diary. His known course in parliament protected him, as he thought, from being either required by his patron to be subservient, or suspected by the public of really being so; and therefore he could safely do that which, by a change of the law, it had now become necessary for him to do if he wished for a seat at all. "Since Curwen's bill," says he, "has declared illegal the purchase of seats in the manner which was formerly practised, there is no choice for a person like myself, but to come into parliament upon such an offer as is now made me, or to decline parliament altogether. And I cannot think that it is my duty to decline it." This seat Romilly held till the dissolution in 1818, when he accepted a requisition from electors in Westminster, upon which a severe contest ensued. One of the two vacant seats was considered as sure for Sir Francis Burdett; the return of Romilly for the other was opposed not only by a ministerial candidate, but by Hunt, Cartwright, and Douglas Kinnaird. Romilly and Burdett were returned, the former standing at the head of the poll from its opening till its close.

The results to which this great victory was expected to have led, were unfortunately never realized. Romilly had a constitutional tendency to hypochondria, or at least to lowness of spirits, which his continual labour both of body and mind prevented for years from reaching a dangerous height, although perhaps this very labour it was, that at length caused the overwrought organism to fall suddenly to pieces. The health of his wife, whom he idolized rather than loved, had for some time caused him serious uneasiness: she became alarmingly unwell. Soon after his election for Westminster, on the 10th of October, he closed abruptly those brief notices of her illness which had lately been the only entries in his diary; and on the 29th of that month she died at Cowes. Her husband travelled to town, labouring, during his journey, or at any rate after it, under an inflammatory fever; and in one of its paroxysms he put an end to his existence, three days after the death of his wife. He died on the 2d of November 1818, when he had nearly completed the sixty-second year of his age.

The public character of Sir Samuel Romilly would be best drawn by a few warm and vigorous strokes, all of which, with no exception worth noticing, would convey images of distinguished excellence. These traits would exhibit his manly and ratiocinative oratory, lighted up into eloquence by the fervour of his moral sense,—the consummate capacity, integrity, and knowledge of the law, and the comprehensive and philanthropic views of legislation, which made it a national misfortune for England that he never became one of her chancellors,—that antique spirit of mental independence, which bowed to the demands of no man, and of no party, not even his own, unless his conscience told him that those demands were just. And these virtues of the statesman and the jurisconsult, which, by their stern majesty, commanded from those that viewed them at a distance an awe not altogether unmingled with fear, were tempered in private life by the warmest and kindest feeling, by the most felicitous union of public labours with personal accomplishments.

His private Memoirs and Diaries, with a selection from his correspondence and other papers, were published by his sons in 1840, in two volumes octavo.

Romford || Ronda.

ROMFORD, a market-town of the county of Essex, in the parish of Hornchurch, and hundred of Havering, eleven miles from London. The population was in 1801, 3179; in 1811, 3244; in 1821, 3777; and in 1831, 4294.

ROMNEY, NEW, a town in the county of Kent, in the Lathe of Sheepway, seventy-two miles from London. It was once a place of much more importance than it is at present. It is surrounded with rich but unhealthy marshes, and is defended against the sea by a strong dyke, called Dunchurch Wall, on which is a good carriage road over the marshes. The population was in 1801, 755; in 1811, 841; in 1821, 962, and in 1831, 983.

ROMORANTIN, an arrondisement of the department of the Loire and Cher in France, seven hundred and thirty square miles in extent. It comprehends six cantons, divided into forty-eight communes, containing, in 1836, 47,722 inhabitants. The capital is the city of the same name at the junction of the Romorantin and the Saudre, and has some beautiful promenades on the bank of the former river. It contains 1200 houses, with 7181 inhabitants, who manufacture to a considerable extent woollen cloth and tanned leather.

ROMSEY, or RUMSEY, a large market and borough town of the county of Hants, seventy-three miles from London. It is in the division of Andover, of the hundred of King's Somborne, and stands on the river Test, on the road between Southampton and Salisbury, and is surrounded by pleasant meadows, which, by irrigation, are rendered highly fertile. It is divided into two parishes; with one church in common, a spacious building in the form of a cross, which, in ancient times, was the chapel of a richly endowed abbey. All the early abbesses were of royal blood, and so distinguished by their piety as to be deemed saints. The trade, which formerly consisted in making woollen stuffs, has nearly been annihilated; by the late law it elected annually four aldermen and twelve counsellors, who chuse the mayor. The population was in 1801, 4274; in 1811, 4297; in 1821, 5128; and in 1831, 5432.

ROMPEE, or ROMPU, in *Heraldry*, is applied to ordinaries that are represented as broken; and to chevrons, bends, or the like, whose upper points are cut off.

RONA, one of the Hebrides, is reckoned about twenty leagues distant from the north-east point of Ness in Lewis, and is about a mile long, and half a mile broad.

RONCESVALLES, a valley in Spain, in the province of Navarne, and district of Sanguessa. It stands at the foot of the Pyrenees, and is the largest valley in the province, but covered with wood. The town of the name is small, but on the great road from France to Madrid, having a church, an Augustin monastery, and an hospital. It has become a place of celebrity from the warlike deeds which the spot has witnessed, both by the defeat of Roland and the twelve peers of France at a remote period, and by the operations under the Duke of Wellington and Marshal Soult.

RONDA, a city of Spain, in the kingdom of Granada, and province of Andalusia. Ronda is about four thousand five hundred feet above the level of the sea, but being surrounded with mountains of vast elevation, it is, in fact, with regard to them, a largely extended valley. The mountains that surround it are more or less covered with snow throughout the whole year; and it is conveyed to the cities of Seville, Cadiz, Gibraltar, and other places, for the daily consumption of their luxurious inhabitants. The plain on which the city stands is one of the most verdant and fertile spots in this the best part of Spain. This city, long a Roman station, under the name of Arunda, abounds with inscriptions, monuments, and ruins of that people, which has been diligently explored by sundry antiquarians. The inhabitants amount to about twenty thousand. Longevity is so very general, that it is a proverb in Andalusia, that in Ronda a man at eighty is still a boy. The public buildings are numerous, but not striking, though some of the churches and convents have the ornaments and riches so commonly belonging to spiritual edifices in this country.

Roorterpoor || Rood.

ROORTERPOOR, a considerable town of Hindustan, province of Delhi, district of Morabad, forty-two miles north by east from Bareilly. Long. 79. 20. E. Lat. 29. 1.

RONSARD, PETER DE, a French poet, was born at the castle of Poissoniere in Vendomois in 1524. He was descended of a noble family, and was educated at Paris in the college of Navarre. Academical pursuits not suiting his genuis, he left college, and became page to the duke of Orleans, who resigned him to James Stuart, king of Scots, married to Magdalene of France. Ronsard continued in Scotland with King James upwards of two years, and afterwards went to France, where he was employed by the duke of Orleans in several negotiations. He accompanied Lazarus de Baif to the diet of Spires. Having from the conversation of this learned man imbibed a passion for the belles-lettres, he studied the Greek language with Baif's son under Dorat. It is reported of Ronsard, that his practice was to study till two o'clock in the morning; and when he went to bed, to awaken Baif, who resumed his place. The muses possessed in his eyes an infinity of charms; and he cultivated them with such success, that he acquired the appellation of the *Prince of Poets* of his time. Henry II. Francis II. Charles IX. and Henry III. loaded him with favours. Having gained the first prize of the *Jeux Floraux*, they thought the reward promised below the merit of the work, and the reputation of the poet. The city of Toulouse caused a Minerva of massy silver of considerable value to be made and sent to him. This present was accompanied with a decree, declaring him *The French Poet*, by way of distinction. Ronsard afterwards made a present of his Minerva to Henry II., and this monarch appeared as much elated with this mark of the poet's esteem for him, as the poet himself could have been had he received the present from his sovereign. Mary, the beautiful and unfortunate queen of Scots, who was equally sensible of his merit with the Toulonese, gave him a rich set of table-plate.

He wrote hymns, odes, a poem called the *Franciad*, eclogues, epigrams, sonnets, &c. In his odes he takes bombast for poetic raptures. He wishes to imitate Pindar; and by labouring too much for lofty expressions, he loses himself in a cloud of words. He is obscure and harsh to the last degree; faults which he might easily have avoided by studying the works of Marot, who had, before he wrote, brought French poetry very near to perfection. But what could be expected from a man who had so little taste, that he called Marot's works, 'a dunghill, from which rich grains of gold, by industrious working, might be drawn?' He has, however, some pieces not destitute of real merit; and there are perhaps few effusions of the French muse more truly poetical than his Four Seasons of the Year, where a most fertile imagination displays all its riches. Ronsard, though it is doubtful whether he ever was in orders, held several benefices in commendam; and he died at Saint-Cosme-les-Tours, one of these, December 27, 1585, being then 61 years of age. He appeared more ridiculous as a man than as a poet; he was particularly vain, and his immoderate indulgence in pleasure, joined to his literary labours, served to hasten his old age. In his 50th year he was weak and valetudinary, and subject to attacks of the gout. He retained his wit, his vivacity, and his readiness at poetic composition, to his last moments. Ronsard's poems have been published in folio, in quarto, and in 10 volumes duodecimo, in 1567.

ROOD, a quantity of land equal to forty square perches, the fourth part of an acre.

ROOF.

Roof.

Definition.

Roof expresses the covering of a house or building, by which its inhabitants or contents are protected from the injuries of the weather. It is perhaps the essential part of a house, and is frequently used to express the whole. To *come under a person's roof*, is to enjoy his protection and society, to dwell with him. *Tectum* was used in the same sense by the Romans. To be within our walls, rather expresses the being in our possession. A roof, therefore, is not only an essential part of a house, but it even seems to be its characteristic feature.

Strictures on various kinds of roofs.

The Greeks, who have perhaps excelled all nations in taste, and who have given the most perfect model of architectonic ordonnance within a certain limit, never erected a building which did not exhibit this part in the most distinct manner; and though they borrowed much of their model from the orientals, as will be evident to any one who compares their architecture with the ruins of Persepolis, and of the tombs in the mountains of Shiraz, they added that form of roof which their own climate taught them was necessary for sheltering them from the rains. The roofs in Persia and Arabia are flat, but those of Greece are without exception sloping. It seems therefore a gross violation of the true principles of taste in architecture, at least in the regions of Europe, to take away or to hide the roof of a house; and it must be ascribed to that rage for novelty which is so powerful in the minds of the rich. Our ancestors seemed to be of a very different opinion, and turned their attention to the ornamenting of their roofs as much as any other part of a building. They showed them in the most conspicuous manner, running them up to a great height; broke them into a thousand fanciful shapes, and stuck them full of highly-dressed windows. We laugh at this, and call it Gothic and clumsy; and our great architects, not to offend any more in this way, conceal the roof altogether by parapets, balustrades, and other contrivances. Our forefathers certainly did offend against the maxims of true taste, when they enriched a part of a house with marks of elegant habitation, which every spectator must know to be a cumbersome garret. But their successors no less offend, who take off the cover of the house altogether, and make it impossible to know whether it is not a mere screen or colonnade we are looking at.

Error of Sir Christopher Wren in the roof of St Paul's.

We cannot help thinking that Sir Christopher Wren erred when he so industriously concealed the roof of St Paul's Church in London. The whole of the upper order is a mere screen. Such a quantity of wall would have been intolerably offensive, had he not given it some appearance of habitation by the mock windows or niches. Even in this state it is gloomy, and it is odd, and a puzzle to every spectator. There should be no puzzle in the design of a building, any more than in that of a discourse. It has been said that the double roof of our great churches which have aisles is an incongruity, looking like a house standing on the top of another house. But there is not the least occasion for such a thought. We know that the aisle is a shed, a cloister. Suppose only that the lower roof or shed is hidden by a balustrade, it then becomes a portico, against which the connoisseur has no objection. Yet there is no difference; for the portico must have a cover, otherwise it is neither a shed, cloister, nor portico, any more than a building without a roof is a house. A house without a visible roof is like a man abroad without his hat; and we may add, that the whim of concealing the chimneys, now so fashionable, changes a house to a barn or storehouse. A house should not be a copy of any thing. It has a title to be an original; and a screen-like house and a pillar-like candlestick are similar solecisms in taste.

Roof.

Little at
tention
to this
of a buil
ing.

The architect is anxious to present a fine object, and a very simple outline discusses all his concerns with the roof. He leaves it to the carpenter, whom he frequently puzzles, by his arrangements, with coverings almost impossible to execute. Indeed it is seldom that the idea of a roof is admitted by him into his great compositions; or if he does introduce it, it is from mere affectation, and we may say pedantry. A pediment is frequently stuck up in the middle of a grand front, in a situation where a roof cannot perform its office; for the rain that is supposed to flow down its sides must be received on the top of the level buildings which flank it. This is a manifest incongruity. The tops of dressed windows, trifling porches, and sometimes a projecting portico, are the only situations in which we see the figure of a roof correspond with its office. Having thus lost sight of the principle, it is not surprising that the draughtsman, for he should not be called architect, runs into every whim; and we see pediment within pediment, a round pediment, a hollow pediment, and, the greatest of all absurdities, a broken pediment. Nothing could ever reconcile us to the sight of a man with a hat without its crown, because we cannot overlook the use of a hat.

Advan-
tages o
high-pi
ed roof

But when one builds a house, ornament alone will not do. We must have a cover; and the enormous expense and other great inconveniences which attend the concealment of this cover by parapets, balustrades, and screens, have obliged architects to consider the pent-roof as admissible, and to regulate its form. Any man of sense, not under the influence of prejudice, would be determined in this by its fitness for answering its purpose. A high-pitched roof will undoubtedly shoot off the rains and snows better than one of a lower pitch. The wind will not so easily blow the dropping rain in between the slates, nor will it have so much power to strip them off. A high-pitched roof will exert a smaller thrust on the walls, both because its strain is less horizontal, and because it will admit of lighter covering. But it is more expensive, because there is more of it. It requires a greater size of timbers to make it equally strong, and it exposes a greater surface to the wind.

ture o
them.

There have been great changes in the pitch of roofs. Our forefathers made them very high, and we make them very low. It does not, however, appear that this change has been altogether the effect of principle. In the simple unadorned habitations of private persons, every thing comes to be adjusted by an experience of inconveniences which have resulted from too low-pitched roofs; and their pitch will always be nearly such as suits the climate and covering. Our architects, however, go to work on different principles. Their professed aim is to make a beautiful object. The sources of the pleasures arising from what we call *taste* are so various, so complicated, and even so whimsical, that it is almost in vain to look for principle in the rules adopted by our professed architects. We cannot help thinking, that much of their practice results from a pedantic veneration for the beautiful productions of Grecian architecture. Such architects as have written on the principles of the art in respect of proportions, or what they call the "ordonnance," are very much puzzled to make a chain of reasoning; and the most that they have made of the Greek architecture is, that it exhibits a nice adjustment of strength and strain. But when we consider the extent of this adjustment, we find that it is wonderfully limited. The whole of it consists of a basement, a column, and an entablature, and the entablature, it is true, exhibits something of a connection with the framework and roof of a wooden building; and we believe that it really originated from this in the hands of the orientals, from whom the Greeks certainly borrowed their forms and their combinations. We could easily show in the ruins of Persepolis, and amongst the tombs in the mountains, which were long prior to the Greek architecture, the fluted column, the base, the Ionic and Corinthian capitals, and the Doric arrangement of lintels, beams, and rafters, all derived from unquestionable principle. The only addition made by the Greeks was the pent-roof; and the changes made by them in the subordinate forms of things are such as we should expect from their exquisite judgment of beauty.

But the whole of this is very limited; and the Greeks, after making the roof a chief feature of a house, went no farther, and contented themselves with giving it a slope suited to their climate. This we have followed, because in the milder parts of Europe we have no cogent reasoning for deviating from it; and if any architect should deviate greatly in a building where the outline is exhibited as beautiful, we should be disgusted; but the disgust, though felt by almost every spectator, has its origin in nothing but habit. In the professed architect or man of education, the disgust arises from pedantry. For there is not such a close connection between the form and uses of a roof as shall give precise determinations; and the mere form is a matter of indifference.

fference tween e ancient eek and e modern ofs.

We should not therefore reprobate the high-pitched roofs of our ancestors, particularly on the Continent. It is there where we see them in all the extremity of the fashion; and the taste is by no means exploded, as it is with us. A baronial castle in Germany and France is seldom rebuilt in the pure Greek style, or even like the modern houses in Great Britain; the high-pitched roofs are retained. We should not call them Gothic, and ugly because Gothic, till we show their principle to be false or tasteless. Now we apprehend that it will be found quite the reverse; and that though we cannot bring ourselves to think them beautiful, we ought to think them so. The construction of the Greek architecture is a transference of the practices that are necessary in a wooden building to a building of stone. To this the Greeks have adhered, in spite of innumerable difficulties. Their marble quarries, however, put it in their power to retain the proportions which habit had rendered agreeable. But it is next to impossible to adhere to these proportions with freestone or with brick, when the order is of magnificent dimensions. Sir Christopher Wren saw this; for his mechanical knowledge was equal to his taste. He composed the front of St Paul's Church in London of two orders, and he coupled his columns; and still the lintels which form the architrave are of such length that they could carry no additional weight, and he was obliged to truss them behind. Had he made but one order, the architrave could not have carried its own weight. It is impossible to execute a Doric entablature of this size in brick. It is attempted in a very noble front, the Academy of Arts in St Petersburg. But the architect was obliged to make the mutules and other projecting members of the corniche of granite, and many of them broke down by their own weight.

effect ur using e.

Here is surely an error in principle. Since stone is the chief material of our buildings, ought not the members of ornamented architecture to be refinements on the essential and unaffected parts of a simple stone building? There is almost as much propriety in the architecture of India, where a dome is made in imitation of a lily or other flower inverted, as in the Greek imitation of a wooden building. The principles of masonry, and not of carpentry, should be seen in our architecture, if we would have it according to the rules of just taste. Now we affirm that this is the characteristic of what is called the Gothic architecture. In this no dependence is had on the transverse strength of stone. No lintels are to be seen, and no extravagant projections. Every stone is pressed to its neighbours, and none is exposed to a transverse strain. The Greeks were enabled to execute their colossal buildings only by using immense blocks of the hardest materials. The Norman mason could raise a building to the skies without using a stone which a labourer could not carry to the top on his back. Their architects studied the principles of equilibrium; and having attained a wonderful knowledge of it, they indulged themselves in exhibiting remarkable instances. We call this false taste, and say that the appearance of insecurity is the greatest fault in it. But this is owing to our habits; our thoughts may be said to run in a wooden train, and certain simple maxims of carpentry are familiar to our imagination; and in the careful adherence to these consist the beauty and symmetry of the Greek architecture. Had we been as much habituated to the equilibrium of pressure, this apparent insecurity would not have met our eye; we should have perceived the strength and relished the ingenuity.

Rational nature of the Gothic architecture.

The Gothic architecture is perhaps entitled to the name of rational architecture, and its beauty is founded on the characteristic distinction of our species. It deserves cultivation; not the pitiful, servile, and unskilled copying of the monuments; this will produce incongruities and absurdities equal to any that have crept into the Greek architecture; but let us examine with attention the nice disposition of the groins and spaundrels; let us study the tracery and knots, not as ornaments, but as useful members; let us observe how they have made their walls like honeycombs, and admire their ingenuity as we pretend to admire the instinct infused by the great Architect into the bee. All this cannot be understood without mechanical knowledge, a thing which few of our professional architects have any share of. Thus would architectonic taste be a mark of skill; and the person who presents the design of a building would know how to execute it, without committing it entirely to the mason and the carpenter.

These observations are not a digression from our subject. The same principles of mutual pressure and equilibrium have a place in roofs and many wooden edifices; and if they had been as much studied as the Normans and Saracens seem to have studied such of them as were applicable to their purposes, we might have produced wooden buildings as far superior to what we are familiarly acquainted with, as the bold and wonderful churches still remaining in Europe are superior to the timid productions of our stone architecture. The centres used in building the bridge of Orleans and the corn-market of Paris are recent instances of what may be done in this way. The last mentioned is a dome of 200 feet diameter, built of fir planks; and there is not a piece of timber in it more than nine feet long, a foot broad, and three inches thick.

The Norman architects often roofed with stone.

The Norman architects frequently roofed with stone. Their wooden roofs were in general very simple, and their professed aim was to dispense with them altogether. Fond of their own science, they copied nothing from a wooden building, and ran into a similar fault with the ancient Greeks. The parts of their buildings which were necessarily of timber were made to imitate stone buildings; and Gothic ornament consists in cramming every thing full of arches and spaundrels. Nothing else is to be seen in their timber-works, nay even in their sculpture. Look at any of the maces or sceptres still to be found about the old cathedrals; they are silver steeples.

Effects of the rivalship between the masons and carpenters of ancient times.

But there appears to have been a rivalship in old times between the masons and the carpenters. Many of the baronial halls are of prodigious width, and are roofed with timber; and the carpenters appeared to have borrowed much knowledge from the masons of those times, and their wide roofs are frequently constructed with great ingenuity. Their aim, like the masons, was to throw a roof over a very wide building, without employing great logs of timber. We have seen roofs sixty feet wide, without having a piece of timber in it above ten feet long and four inches square. The Parliament House, and the Tron Church of Edinburgh, and the great hall of Tarnaway Castle, near Forres, are specimens of those roofs. They are very numerous on the Continent. Indeed Britain retains few monuments of private magnificence. Aristocratic state never was so great with us; and the rancour of our civil wars gave most of the performances of the carpenter to the flames. Westminster Hall exhibits a specimen of the false taste of the Norman roofs. It contains the essential parts, indeed, very properly disposed; but they are hidden, or intentionally covered, with what is conceived to be ornamental; and this is an imitation of stone arches crammed in between slender pillars, which hang down from the principal frames, trusses, or rafters. In a pure Norman roof, such as Tarnaway Hall, the essential parts are exhibited as things understood, and therefore relished. They are refined and ornamented; and it is here that the inferior kind of taste or the want of it may appear. And here we do not mean to defend all the whims of our ancestors; but we assert that it is no more necessary to consider the members of a roof as things to be concealed, like a garret or privy, than the members of a ceiling, which form the most beautiful part of the Greek architecture. Should it be said that a roof is only a thing to keep off the rain, it may be answered, that a ceiling is only to keep off the dust, or the floor to be trodden under foot, and that we should have neither compartments in the one, nor inlaid work or carpets on the other. The structure of a roof may therefore be exhibited with propriety, and made an ornamental feature. This has been done even in Italy. The church of Santa Maria Maggiore in Rome, and several others, are specimens; but it must be acknowledged that the forms of the principal frames of these roofs, which resemble those of our modern buildings, are very unfit for agreeable ornament. As we have already observed, our imaginations have not been made sufficiently familiar with the principles, and we are rather alarmed than pleased with the appearance of the immense logs of timber which form the couples of these roofs, and hang over our heads with every appearance of weight and danger. It is quite otherwise with the ingenious roofs of the German and Norman architects. Slender timbers, interlaced with great symmetry, and thrown by necessity into figures which are naturally pretty, form altogether an object which no carpenter can view without pleasure. And why should the gentleman refuse himself the same pleasure of beholding scientific ingenuity?

Necessity of science in forming roofs.

The roof is in fact the part of the building which requires the greatest degree of skill, and where science will be of more service than in any other part. The architect seldom knows much of the matter, and leaves the task to the carpenter. The carpenter considers the framing of a great roof as the touchstone of his art; and nothing indeed tends so much to show his judgment and his fertility of resource.

The little attention hitherto paid to it.

It must therefore be very acceptable to the artist to have a clear view of the principles by which this difficult problem may be solved in the best manner, so that the roof may have all the strength and security that can be wished for, without an extravagant expense of timber and iron. We have said that mechanical science can give great assistance in this matter. We may add, that the framing of carpentry, whether for roofs, floors, or any other purpose, affords one of the most elegant and most satisfactory applications which can be made of mechanical science to the arts of common life. Unfortunately the practical artist is seldom possessed even of the small portion of science which would almost insure his practice from all risk of failure; and even our most experienced carpenters have seldom any more knowledge than what arises from their experience and natural sagacity. The most approved author in our language is Price in his British Carpenter. Mathurin Jousse is in like manner the author most in repute in France; but the publications of both these authors are void of every appearance of principle. It is not uncommon to see the works of carpenters of the greatest reputation tumble down, in consequence of mistakes from which the most elementary knowledge would have saved them.

Purpose this arti

We shall attempt in this article to give an account of the leading principles of this art, in a manner so familiar and palpable, that any person who knows the common properties of the lever, and the composition of motion, shall so far understand them as to be able, on every occasion, so to dispose his materials, with respect to the strains to which they are to be exposed, that he shall always know the effective strain on every piece, and shall, in most cases, be able to make the disposition such as to derive the greatest possible advantage from the materials which he employs.

Principle which re- gulate th strength the materials.

It is evident that the whole must depend on the principles which regulate the strength of the materials, relative to the manner in which this strength is exerted, and the manner in which the strain is laid on the piece of matter. With respect to the first, this is not the proper place for considering it, and we must refer the reader to the article Strength of Materials in Mechanics. We shall just borrow from that article two or three propositions suited to our purpose.

The force with which the materials of our edifices, roofs, floors, machines, and framings of every kind, resist being broken or crushed, or pulled asunder, is immediately or ultimately the cohesion of their particles. When a weight hangs by a rope, it tends either immediately to break all the fibres, overcoming the cohesion amongst the particles of each, or it tends to pull one parcel of them from amongst the rest, with which they are joined. This union of the fibres is brought about by some kind of gluten, or by twisting, which causes them to bind each other so hard that any one will break rather than come out, so much is it withheld by friction. The ultimate resistance is therefore the cohesion of the fibre; and the force or strength of all fibrous materials, such as timber, is exerted in much the same manner. The fibres are either broken or pulled out from among the rest. Metals, stone, glass, and the like, resist being pulled asunder by the simple cohesion of their parts.

The force which is necessary for breaking a rope or wire is a proper measure of its strength. In like manner, the force necessary for tearing directly asunder any rod of wood or metal, breaking all its fibres, or tearing them from amongst each other, is a proper measure of the united strength of all these fibres; and it is the simplest strain to which they can be exposed, being just equal to the sum of the forces necessary for breaking or disengaging each fibre. And, if the body is not of a fibrous structure, which is the case with metals, stones, glass, and many other substances, this force is still equal to the simple sum of the cohesive forces of each particle which is separated by the fracture. Let us distinguish this mode of exertion of the cohesion of the body by the name of its *absolute strength*.

When solid bodies are, on the contrary, exposed to great compression, they can resist only a certain degree. A piece of clay or lead will be squeezed out; a piece of freestone will be crushed to powder; a beam of wood will be crippled, swelling out in the middle, and its fibres lose their mutual cohesion, after which it is easily crushed by the load. A notion may be formed of the manner in which these strains are resisted, by conceiving a cylindrical pipe filled with small shot, well shaken together, so that each sphericle is lying in the closest manner possible, that is, in contact with six others in the same vertical plane, this being the position in which the shot will take the least room. Thus each touches the rest in six points. Now suppose them all united, in these six points only, by some cement. This assemblage will stick together and form a cylindrical pillar, which may be taken out of its mould. Now suppose this pillar standing upright, and loaded above. The supports arising from the cement act obliquely, and the load tends either to force them asunder laterally, or to make them slide on each other: either of these things happening, the whole is crushed to pieces. The resistance of fibrous materials to such a strain is a little more intricate, but may be explained in a way very similar.

A piece of matter of any kind may also be destroyed by wrenching or twisting it. We can easily form a notion of its resistance to this kind of strain by considering what would happen to the cylinder of small shot if treated in this way.

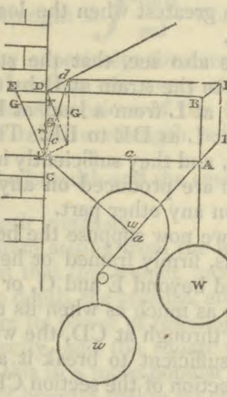
akness
relation
trans-
se
ains.

And, lastly, a beam, or a bar of metal, or piece of stone or other matter, may be broken transversely. This will happen to a rafter or joist supported at the ends when overloaded, or to a beam having one end stuck fast in a wall and a load laid on its projecting part. This is the strain to which materials are most commonly exposed in roofs; and, unfortunately, it is the strain which they are the least able to bear; or rather it is the manner of application which causes an external force to excite the greatest possible immediate strain on the particles. It is against this that the carpenter must chiefly guard, avoiding it when in his power, and in every case diminishing it as much as possible. It is necessary to give the reader a clear notion of the great weakness of materials in relation to this transverse strain. But we shall do nothing more, referring him to the articles Strain, and Stress, and Strength.

Let ABCD (fig. 1) represent the side of a beam projecting horizontally from a wall in which it is firmly fixed, and let it be loaded with a weight W appended to its extremity. This tends to break it; and the least reflection will convince any person, that if the beam is equally strong throughout, it will break in the line CD, even with the surface of the wall. It will open at D, while C will serve as a sort of joint, round which it will turn. The cross section through the line CD is for this reason called the *section of fracture*; and the horizontal line drawn through C on its under surface is called the *axis of fracture*. The fracture is made by tearing asunder the fibres, sueh as DE or FG. Let us suppose a real joint at C, and that the beam is really sawed through along CD, and that in place of its natural fibres, threads are substituted all over the section of fracture. The weight now tends to break these threads, and it is our business to find the force necessary for this purpose.

Fig. 1.



It is evident that DCA may be considered as a bended lever, of which C is the fulcrum. If f be the force which will just balance the cohesion of a thread when hung on it so that the smallest addition will break it, we may find the weight which will be sufficient for this purpose when hung on at A, by saying, $AC : CD = f : \varphi$, and φ will be the weight which will just break the thread, by hanging φ by the point A. This gives us $\varphi = f \times \frac{CD}{CA}$. If the weight be hung on at a, the force just sufficient for breaking the same thread will be $= f \times \frac{CD}{Ca}$. In like manner, the force φ, which must be hung on at A in order to break an equally strong or an equally resisting fibre at F, must be $= f \times \frac{CF}{CA}$. And so on of all the rest.

If we suppose all the fibres to exert equal resistances at the instant of fracture, we know, from the simplest elements of mechanics, that the resistance of all the particles in the line CD, each acting equally in its own place, is the same as if all the individual resistances were united in the middle point g. Now this total resistance is the resistance or strength f of each particle, multiplied by the number of particles. This number may be expressed by the line CD, because we have no reason to suppose that they are at unequal distances. Therefore, in comparing different sections together, the number of particles in each are as the sections themselves. Therefore DC may represent the number of particles in the line DC. Let us call this line the depth of the beam, and express it by the symbol d. And since we are at present treating of roofs whose rafters and other parts are commonly of uniform breadth, let us call AH or BI the breadth of the beam, and express it by b, and let CA be called its length l. We may now express the strength of the whole line CD by $f \times d$, and we may suppose it all concentrated in the middle point g. Its mechanical energy, therefore, by which it resists the energy of the weight w, applied at the distance l, is $f \times CD \times Cg$, whilst the momentum of w is $w \times CA$. We must therefore have $f \times CD \times Cg = w \times CA$, or $fd \times \frac{1}{2}d = wl$, and $fd : w = l : \frac{1}{2}d$, or $fd : w = 2l : d$. That is, twice the length of the beam is to its depth as the absolute strength of one of its vertical planes to its relative strength, or its power of resisting this transverse fracture.

It is evident, that what has been now demonstrated of the resistance exerted in the line CD, is equally true of every line parallel to CD in the thickness or breadth of the beam. The absolute strength of the whole section of fracture is represented by fdb, and we still have $2l : d = fdb : w$; or twice the length of the beam is to its depth as the absolute strength to the relative strength. Suppose the beam twelve feet long and one foot deep; then whatever be its absolute strength, the twenty-fourth part of this will break it if hung at its extremity.

But even this is too favourable a statement. All the fibres are supposed to act alike in the instant of fracture. But this is not true. At the instant that the fibre at D breaks, it is stretched to the utmost, and is exerting its whole force. But at this instant the fibre at g is not so much stretched, and it is not then exerting its utmost force. If we suppose the extension of the fibres to be as their distance from C, and the actual exertion of each to be as their extensions, it may easily be shown (see Strength and Strain), that the whole resistance is the same as if the full force of all the fibres were united at a point r distant from C by one third of CD. In this case we must say, that the absolute strength is to the relative strength as three times the length to the depth; so that the beam is weaker than by the former statement in the proportion of two to three.

Even this is more strength than experiment justifies, and we can see an evident reason for it. When the beam is strained, not only are the upper fibres stretched, but the lower fibres are compressed. This is very distinctly seen, if we attempt to break a piece of cork cut into the shape of a beam. This being the case, C is not the centre of fracture. There is some point c which lies between the fibres which are stretched and those that are compressed. This fibre is neither stretched nor squeezed, and this point is the real centre of fracture; and the lever by which a fibre D resists, is not DC, but a shorter one Dc, and the energy of the whole resistances must be less than by the second statement. Till we know the proportion between the dilatability and compressibility of the parts, and the relation between the dilatations of the fibres and the resistances which they exert in this state of dilatation, we cannot positively say where the point *c* is situated, nor what is the sum of the actual resistances, or the point where their action may be supposed concentrated. The firmer woods, such as oak and chestnut, may be supposed to be but slightly compressible; we know that willow and other soft woods are very compressible. These last must therefore be weaker; for it is evident, that the fibres which are in a state of compression do not resist the fracture. It is well known, that a beam of willow may be cut through from C to *g* without weakening it in the least, if the cut be filled up by a wedge of hard wood stuck in.

We can only say, that very sound oak and red fir have the centre of effort so situated, that the absolute strength is to the relative strength in a proportion of not less than that of three and a half times the length of the beam to its depth. A square inch of sound oak will carry about 8000 pounds. If this bar be firmly fixed in a wall, and project twelve inches, and be loaded at the extremity with 200 pounds, it will be broken. It will just bear 190, its relative strength being $\frac{1}{42}$ of its absolute strength; and this is the case only with the finest pieces, so placed that their annual plates or layers are in a vertical position. A larger log is not so strong transversely, because its plates lie in various directions round the heart.

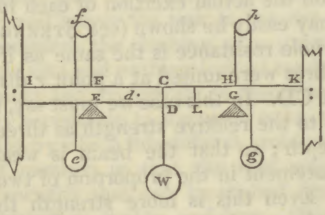
Practical inferences.

These observations are enough to give us a distinct notion of the vast diminution of the strength of timber when the strain is across it; and we see the justice of the maxim which we inculcated, that the carpenter, in framing roofs, should avoid as much as possible the exposing his timbers to transverse strains. But this cannot be avoided in all cases. Nay, the ultimate strain arising from the very nature of a roof is transverse. The rafters must carry their own weight, and this tends to break them across. An oak beam a foot deep will not carry its own weight if it project more than sixty feet. Besides this, the rafters must carry the lead, tiling, or slates. We must therefore consider this transverse strain a little more particularly, so as to know what strain will be laid on any part by an unavoidable load, imposed either at that part or at any other.

Effect when beams are supported at the ends and loaded in the middle.

We have hitherto supposed, that the beam had one of its ends fixed in a wall, and that it was loaded at the other end. This is not an usual arrangement, and was taken merely as affording a simple application of the mechanical principles. It is much more usual to have the beam supported at the ends, and loaded in the middle. Let the beam FEGH (fig. 2) rest on the props E and G, and be loaded at its middle point C with a weight W. It is required to determine the strain at the section CD. It is plain that the beam will receive the same support, and suffer the same strain, if, instead of the blocks E and G, we substitute the ropes F*fe*, H*hg*, going over the pulleys *f* and *g*, and loaded with proper weights *e* and *g*. The weight *e* is equal to the support given by the block E; and *g* is equal to the support given by G. The sum of *e* and *g* is equal to W; and on whatever point W is hung, the weights *e* and *g* are to W in the proportion of DG and DE to GE. Now, in this state of things, it appears that the strain on the section CD arises immediately from the upward action of the ropes F*f* and H*h*, or the upward pressions of the blocks E and G; and that the office of the weight W is to oblige the beam to oppose this strain. Things are in the same state in respect of strain as if a block were substituted at D for the weight W, and the weights *e* and *g* were hung on at E and G, only the directions will be opposite. The beam tends to break in the section CD, because the ropes pull it upwards at E and G, whilst a weight W holds it down at C. It tends to open at D, and C becomes the centre of fracture. The strain therefore is the same as if the half ED were fixed in the wall, and a weight equal to *g*, that is, to the half of W, were hung on at G.

Fig. 2.



Hence we conclude, that a beam supported at both ends, but not fixed there, and loaded in the middle, will carry twice as much weight as it can carry at its extremity, when the other extremity is fast in a wall.

The strain occasioned at any point L by a weight W, hung on at any other point D, is $= W \times \frac{DE}{EG} \times LG$. For EG is to ED as W to the pressure occasioned at G. This would be balanced by some weight *g* acting over the pulley *h*; and this tends to break the beam at L, by acting on the lever GL. The pressure at G is $W \times \frac{DE}{EG}$, and therefore the strain at L is $W \times \frac{DE}{EG} \times LG$.

In like manner, the strain occasioned at the point D by the weight W hung on there, is $W \times \frac{DE}{EG} \times DG$; which is therefore equal to $\frac{1}{2}$ W when D is the middle point.

Hence we see that the general strain on the beam arising from one weight, is proportional to the rectangle of the parts of the beam (for $\frac{W \times DE \times DG}{EG}$ is as $DE \times DG$), and is greatest when the load is laid on the middle of the beam.

We also see, that the strain at L by a load at D, is equal to the strain at D by the same load at L. And the strain at L from a load at D is to the strain by the same load at L as DE to LE. These are all very obvious corollaries, and they sufficiently inform us concerning the strains which are produced on any part of the timber by a load laid on any other part.

If we now suppose the beam to be fixed at the two ends, that is, firmly framed or held down by blocks at I and K, placed beyond E and G, or framed into posts, it will carry twice as much as when its ends were free. For suppose it sawn through at CD, the weight W hung on there will be just sufficient to break it at E and G. Now restore the connection of the section CD, it will require another weight W to break it there at the same time.

Therefore, when a rafter, or any piece of timber, is firmly connected with three fixed points, G, E, I, it will bear a greater load between any two of them than if its connection with the remote point were removed; and if it be fastened in four points, G, E, I, K, it will be twice as strong in the middle part as without the two remote connections.

One is apt to expect from this that the joist of a floor will be much strengthened by being firmly built in the wall. It is a little strengthened; but the hold which can thus be given to it is much too short to be of any sensible service, and it tends greatly to shatter the wall, because, when it is bent down by a load, it forces up the wall with a momentum of a long lever. Judicious builders therefore take care not to bind the joists tight in the wall. But when the joists of adjoining rooms lie in the same direction, it is a great advantage to make them of one piece. They are then twice as strong as when made in two lengths.

Infere

It is easy to deduce from these premises the strain on any point which arises from the weight of the beam itself, or from any load which is uniformly diffused over the whole or any part. We may always consider the whole of the weight which is thus uniformly diffused over any part as united in the middle point of that part; and if the load is not uniformly diffused, we may still suppose it united at its centre of gravity. Thus, to know the strain at D arising from the weight of the whole beam, we may suppose the whole weight accumulated in its middle point D. Also the strain at L, arising from the weight of the part ED, is the same as if this weight were accumulated in the middle point *d* of ED; and it is the same as if half the weight of ED were hung on at D. For the real strain at L is the upward pressure at G, acting by the lever GL. Now, calling the weight of the part DE *e*, this upward pressure will be $\frac{e \times d\mathrm{E}}{\mathrm{EG}}$, or $\frac{\frac{1}{2}e \times \mathrm{DE}}{\mathrm{EG}}$.

Therefore the strain on the middle of a beam, arising from its own weight, or from any uniform load, is the weight of the beam or its load $\times \frac{\mathrm{ED}}{\mathrm{EG}} \times \mathrm{DG}$; that is, half the weight of the beam or load multiplied or acting by the lever DG; for $\frac{\mathrm{ED}}{\mathrm{EG}}$ is $\frac{1}{2}$.

Also the strain at L, arising from the weight of the beam, or the uniform load, is $\frac{1}{2}$ the weight of the beam or load acting by the lever LG. It is therefore proportional to LG, and is greatest of all at D. Therefore a beam of uniform strength throughout, uniformly loaded, will break in the middle.

elation tween e weight strains d the re- ive ength.

It is of importance to know the relation between the strains arising from the weights of the beams, or from any uniformly diffused load, and the relative strength. We have already seen, that the relative strength is $f\frac{dbd}{ml}$, where *m* is a number to be discovered by experiment for every different species of materials. Leaving out every circumstance but what depends on the dimensions of the beam, viz. *d*, *b*, and *l*, we see that the relative strength is in the proportion of $\frac{d^2b}{l}$, that is, as the breadth and the square of the depth directly, and the length inversely.

Now, to consider, first, the strain arising from the weight of the beam itself, it is evident that this weight increases in the same proportion with the depth, the breadth, and the length of the beam. Therefore its power of resisting this strain must be as its depth directly, and the square of its length inversely. To consider this in a more popular manner, it is plain that the increase of breadth makes no change in the power of resisting the actual strain, because the load and the absolute strength increase in the same proportion with the breadth. But, by increasing the depth, we increase the resisting section in the same proportion, and therefore the number of resisting fibres and the absolute strength; but we also increase the weight in the same proportion. This makes a compensation, and the relative strength is yet the same. But, by increasing the depth, we have not only increased the absolute strength, but also its mechanical energy. For the resistance to fracture is the same as if the full strength of each fibre was exerted at the point which we called the centre of effort; and we showed that the distance of this from the under side of the beam was a certain portion (a half, a third, a fourth, &c.) of the whole depth of the beam. This distance is the arm of the lever, by which the cohesion of the wood may be supposed to act. Therefore this arm of the lever, and consequently the energy of the resistance, increases in the proportion of the depth of the beam, and this remains uncompensated by any increase of the strain. On the whole, therefore, the power of the beam to sustain its own weight increases in the proportion of its depth. But, on the other hand, the power of withstanding a given strain applied at its extremity, or to any aliquot part of its length, is diminished as the length increases, or is inversely as the length; and the strain arising from the weight of the beam also increases as the length. Therefore the power of resisting the strain actually exerted on it by the weight of the beam is inversely as the square of the length. On the whole, therefore, the power of a beam to carry its own weight varies in the proportion of its depth directly and the square of its length inversely.

As this strain is frequently a considerable part of the whole, it is proper to consider it apart, and then to reckon only on what remains for the support of any extraneous load.

Power of a beam to carry a load uniformly diffused over its length.

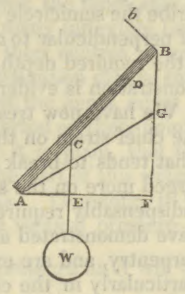
In the next place, the power of a beam to carry any load which is uniformly diffused over its length, must be inversely as the square of the length; for the power of withstanding any strain applied to an aliquot part of the length (which is the case here, because the load may be conceived as accumulated at its centre of gravity, the middle point of the beam) is inversely as the length; and the actual strain is as the length, and therefore its momentum is as the square of the length. Therefore the power of a beam to carry a weight uniformly diffused over it, is inversely as the square of the length.

It is here understood, that the uniform load is of some determined quantity for every foot of the length, so that a beam of double length carries a double load.

Effect when the action of the load is oblique.

We have hitherto supposed that the forces which tend to break a beam transversely are acting in a direction perpendicular to the beam. This is always the case in level floors loaded in any manner; but in roofs, the action of the load tending to break the rafters is oblique, because gravity always acts in vertical lines. It may also frequently happen, that a beam is strained by a force acting obliquely. This modification of the strain is easily discussed. Suppose that the external force, which is measured by the weight W in fig. 1, acts in the direction A*w*′ instead of AW. Draw C*a*′ perpendicular to A*w*. Then the momentum of this external force is not to be measured by W × AC, but by W × *a*′C. The strain therefore by which the fibres in the section of fracture DC are torn asunder, is diminished in the proportion of CA to C*a*′, that is, in the proportion of radius to the sine of the angle CA*a*′, which the beam makes with the direction of the external force.

Fig. 3.



To apply this to our purpose in the most familiar manner, let AB (fig. 3) be an oblique rafter of a building, loaded with a weight W suspended to any point C, and thereby occasioning a strain in some part D. We have already seen, that the immediate cause of the strain on D is the re-action of the support which is given to the point B. The rafter may at present be considered as a lever, supported at A, and pulled down by the line CW. This occasions a pressure on B, and the support acts in the opposite direction to the action of the lever, that is, in the direction B*b*, perpendicular to BA. This tends to break the beam in every part. The pressure exerted at B is $\frac{\mathrm{W} \times \mathrm{AE}}{\mathrm{AB}}$, AE being a horizontal line. Therefore the strain at D will be $\frac{\mathrm{W} \times \mathrm{AE}}{\mathrm{AB}} \times \mathrm{BD}$. Had the beam been lying horizontally, the strain at D, from the weight W suspended at C, would have been $\frac{\mathrm{W} \times \mathrm{AC}}{\mathrm{AB}} \times \mathrm{BD}$.

It is therefore diminished in the proportion of AC to AE, that is, in the proportion of radius to the cosine of the elevation, or in the proportion of the secant of elevation to the radius.

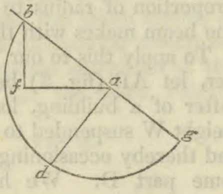
It is evident, that this law of diminution of the strain is the same whether the strain arises from a load on any part of the rafter, or from the weight of the rafter itself, or from any load uniformly diffused over its length, provided only that these loads act in vertical lines.

Strength of roofs having different elevations compared.

We can now compare the strength of roofs which have different elevations. Supposing the width of the building to be given, and that the weight of a square yard of covering is also given. Then, because the load on the rafter will increase in the same proportion with its length, the load on the slant-side BA of the roof will be to the load of a similar covering on the half AF of the flat roof, of the same width, as AB to AF. But the transverse action of any load on AB, by which it tends to break it, is to that of the same load on AF as AF to AB. The transverse strain therefore is the same on both, the increase of real load on AB being compensated by the obliquity of its action. But the strengths of beams to resist equal strains, applied to similar points, or uniformly diffused over them, are inversely as their lengths, because the momentum or energy of the strain is proportional to the length. Therefore the power of AB to withstand the strain to which it is really exposed, is to the power of AF to resist its strain as AF to AB. If, therefore, a rafter AG of a certain scantling is just able to carry the roofing laid on it, a rafter AB of the same scantling, but more elevated, will be too weak in the proportion of AG to AB. Therefore steeper roofs require stouter rafters, in order that they may be equally able to carry a roofing of equal weight per square yard. To be equally strong, they must be made broader, or placed nearer to each other, in the proportion of their greater length, or they must be made deeper in the subduplicate proportion of their length. The following easy construction will enable the artist not familiar with computation to proportion the depth of the rafter to the slope of the roof.

Let the horizontal line *a f* (fig. 4) be the proper depth of a beam whose length is half the width of the building; that is, such as would make it fit for carrying the intended tiling laid on a flat roof. Draw the vertical line *fb*, and the line *ab* having the elevation of the rafter; make *ag* equal to *af*, and describe the semicircle *bdg*; draw *ad* perpendicular to *ab*, then *ad* is the required depth. The demonstration is evident.

Fig. 4.



We have now treated in sufficient detail what relates to the chief strain on the component parts of a roof, namely, what tends to break them transversely; and we have enlarged more on the subject than what the present occasion indispensably required, because the propositions which we have demonstrated are equally applicable to all framings of carpentry, and are even of greater moment in many cases, particularly in the construction of machines. These consist of levers in various forms, which are strained transversely; and similar strains frequently occur in many of the supporting and connecting parts. We shall give, in another article, an account of the experiments which have been made by different naturalists, in order to ascertain the absolute strength of some of the materials which are most generally framed together in buildings and engines. The house-carpenter will derive from them absolute numbers, which he can apply to his particular purposes by means of the propositions which we have now established.

We proceed, in the next place, to consider the other strains to which the parts of roofs are exposed, in consequence of the support which they mutually give each other, and the pressures, or *thrusts*, as they are called in the language of the house-carpenter, which they exert on each other, and on the walls or piers of the building.

Effect of other strains.

Let a beam or piece of timber AB (fig. 5) be suspended by two lines AC, BD; or let it be supported by two props AE, BF, which are perfectly moveable round their remote extremities E, F, or let it rest on the two polished planes KAH, LBM. Moreover, let G be the centre of gravity of the beam, and let GN be a line through the centre of gravity perpendicular to the horizon. The beam will not be in equilibrio unless the vertical line GN either passes through P, the point in which the directions of the two lines AC, BD, or the directions of the two props EA, FB, or the perpendiculars to the two planes KAH, LBM intersect each other, or is parallel to these directions. For the supports given by the lines or props are unquestionably exerted in the direction of their lengths, and it is well known in mechanics that the supports given by planes are exerted in a direction perpendicular to those planes in the points of contact; and we know that the weight of the beam acts in the same manner as if it were all accumulated in its centre of gravity G, and that it acts in the direction GN perpendicular to the horizon. Moreover, when a body is in equilibrio between three forces, they are acting in one plane, and their directions are either parallel or they pass through one point.

Fig. 5.

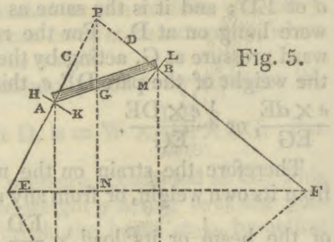


Fig. 6.

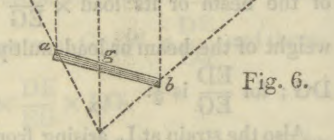

The support given to the beam is therefore the same as if it were suspended by two lines which are attached to the single point P. We may also infer, that the points of suspension C, D, the points of support E, F, the points of contact A, B, and the centre of gravity G, are all in one vertical plane.

When this position of the beam is disturbed by any external force, there must either be a motion of the points A and B round the centres of suspension C and D, or of the props round these points of support E and F, or a sliding of the ends of the beam along the polished planes KAH and LBM; and in consequence of these motions the centre of gravity G will go out of its place, and the vertical line GN will no longer pass through the point where the directions of the supports intersect each other. If the centre of gravity rises by this motion, the body will have a tendency to recover its former position, and it will require force to keep it away from it. In this case the equilibrium may be said to be *stable*, or the body to have *stability*. But if the centre of gravity descends when the body is moved from the position of equilibrium, it will tend to move still farther; and so far will it be from recovering its former position, that it will now fall. This equilibrium may be called a *tottering equilibrium*. These accidents depend on the situations of the points A, B, C, D, E, F; and they may be determined by considering the subject geometrically. It does not much interest us at present; it is rarely that the equilibrium of suspension is tottering, or that of props is stable. It is evident, that if the beam were suspended by lines from the point P, it would have stability, for it would swing like a pendulum round P, and therefore would always tend towards the position of equilibrium. The intersection of the lines of support would still be at P, and the vertical line drawn through the centre of gravity, when in any other situation, would be on that side of P towards which this centre has been moved. Therefore, by the rules of pendulous bodies, it tends to come back. This would be more remarkably the case if the points of suspension C and D were on the same side of the point P with the points of attachment A and B; for in this case the new point of intersection of the lines of support would shift to the opposite side, and be still further from the vertical line through the new position of the centre of gravity. But if the points of suspension and of attachment are on opposite sides of P, the new point of intersection may shift to the same side with the centre of gravity, and lie beyond the vertical line. In this case the equilibrium is tottering. It is easy to perceive, too, that if the equilibrium of suspension from the points C and D be stable, the equilibrium on the props AE and BF must be tottering. It is not necessary for our present purpose to engage more particularly in this discussion.

It is plain that, with respect to the mere momentary equilibrium, there is no difference in the support by threads, props, or planes, and we may substitute the one for the other. We shall find this substitution extremely useful, because we easily conceive distinct notions of the support of a body by strings.

Observe farther, that if the whole figure be inverted, and strings be substituted for props, and props for strings, the equilibrium will still obtain. For by comparing fig. 5 with fig. 6, we see that the vertical line through the centre of gravity will pass through the intersection of the two strings or props; and this is all that is necessary for the equilibrium; only it must be observed in the substitution of props for threads, and of threads for props, that if it be done without inverting the whole figure, a stable equilibrium becomes a tottering one, and *vice versa.*

E mples.

This is a most useful proposition, especially to the unlettered artisan, and enables him to make a practical use of problems which the greatest mechanical geniuses have found it no easy task to solve. An instance will show the extent and utility of it. Suppose it were required to make a mansard or kirb roof whose width is AB (fig. 7), and consisting of the four equal rafters AC, CD, DE, EB. There can be no doubt but that its best form is that which will put all the parts in equilibrio, so that no ties or stays may be necessary for opposing the unbalanced thrust of any part of it. Make a chain *acdeb* (fig. 8) of four equal pieces, loosely connected by pin-joints, round which the parts are perfectly moveable. Suspend this from two pins *a*, *b*, fixed in a horizontal line. This chain or festoon will arrange itself in such a form that its parts are in equilibrio. Then we know that if the figure be inverted, it will compose the frame or truss of a kirb-roof $a\gamma\delta\epsilon b$, which is also in equilibrio, the thrusts of the pieces balancing each other in the same manner that the mutual pulls of the hanging festoon *acdeb* did. If the proportion of the height *df* to the width *ab* is not such as pleases, let the pins *a*, *b* be placed nearer or more distant, till a proportion between the width and height is obtained which pleases, and then make the figure ACDEB, fig. 7, similar to it. It is evident that this proposition will apply in the same manner to the determination of the form of an arch of a bridge; but this is not a proper place for a further discussion.

Fig. 7.

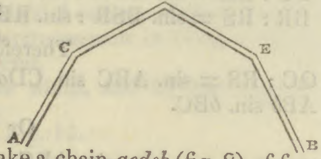

Fig. 8.

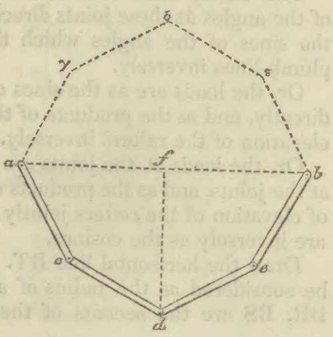

Fig. 9.

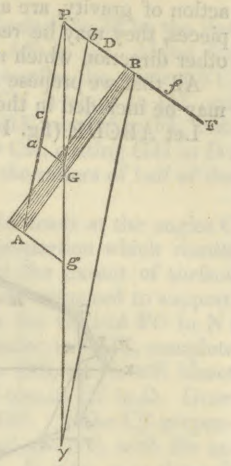


We are now enabled to compute all the thrusts and other pressures which are exerted by the parts of a roof on each other and on the walls. Let AB (fig. 9) be a beam standing anyhow obliquely, and G its centre of gravity. Let us suppose that the ends of it are supported in any directions AC, BD, by strings, props, or planes. Let these directions meet in the point P of the vertical line PG passing through its centre of gravity. Through G draw lines G*a*, G*b* parallel to PB, PA. Then

$$\left.\begin{array}{l}\text{The weight of the beam}\\ \text{The pressure or thrust at A}\\ \text{And the pressure at B}\end{array}\right\}\text{ is proportional to }\left\{\begin{array}{l}PG\\ Pa\\ Pb.\end{array}\right.$$

For when a body is in equilibrio between three forces, these forces are proportional to the sides of a triangle which have their directions.

In like manner, if A *g* be drawn parallel to P *b*, we shall have

$$\left.\begin{array}{l}\text{Weight of the beam}\\ \text{Thrust on A}\\ \text{And thrust on B}\end{array}\right\}\text{ proportional to }\left\{\begin{array}{l}Pg\\ PA\\ Ag\end{array}\right.$$

Or, drawing Bγ parallel to P*a*,

$$\left.\begin{array}{l}\text{Weight of the beam}\\ \text{Thrust at A}\\ \text{And thrust at B}\end{array}\right\}\text{ proportional to }\left\{\begin{array}{l}P\gamma\\ B\gamma\\ PB.\end{array}\right.$$

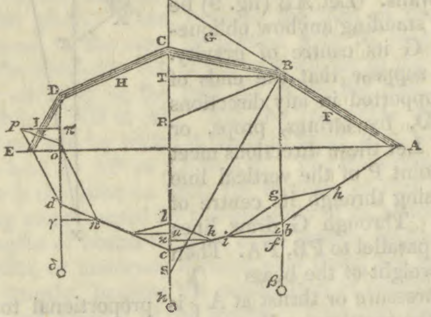
The proper form of a roof is that which puts the whole in equilibrio.

It cannot be disputed that, if strength alone be considered, the proper form of a roof is that which puts the whole in equilibrio, so that it would remain in that shape although all the joints were perfectly loose or flexible. If it has any other shape, additional ties or braces are necessary for preserving it, and the parts are unnecessarily strained. When this equilibrium is obtained, the rafters which compose the roof are all acting on each other in the direction of their lengths; and by this action, combined with their weights, they sustain no strain but that of compression, the strain of all others that they are the most able to resist. We may consider them as so many inflexible lines having their weights accumulated in their centres of gravity. But it will allow an easier investigation of the subject, if we suppose the weights to be at the joints, equal to the real vertical pressures which are exerted on these points. These are very easily computed; for it is plain, that the weight of the beam AB (fig. 9) is to the part of this weight that is supported at B as AB to AG. Therefore, if W represent the weight of the beam, the vertical pressure at B will be $W \times \frac{AG}{AB}$, and the vertical pressure at A will be $W \times \frac{BG}{AB}$. In like manner, the prop BF being considered as another beam, and *f* as its centre of gravity and *w* as its weight, a part of this weight, equal to $w \times \frac{fF}{BF}$, is supported at B, and the whole vertical pressure at B is $W \times \frac{AG}{AB} + w \times \frac{fF}{BF}$. And thus we greatly simplify the consideration of the mutual thrusts of roof frames. We need hardly observe, that although these pressures by which the parts of a frame support each other in opposition to the vertical action of gravity, are always exerted in the direction of the pieces, they may be resolved into pressures acting in any other direction which may engage our attention.

All that we propose to deliver on this subject at present may be included in the following proposition.

Let ABCDE (fig. 10) be an assemblage of rafters in a vertical plane, resting on two fixed points A and E in a horizontal line, and perfectly moveable round all the joints A, B, C, D, E; let it be further supposed to be in equilibrio, and let us investigate what adjustment of the different circumstances of weight and inclination of its different parts is necessary for producing this equilibrium.

Fig. 10.



Let F, G, H, I, be the centres of gravity of the different rafters, and let these letters express the weights of each. Then, by what has been said above, the weight which presses B directly downwards is $F \times \frac{AF}{AB} + G \times \frac{CG}{BC}$.

The weight on C is in like manner $G \times \frac{BG}{BC} + D \times \frac{DH}{CD}$,

and that on D is $H \times \frac{CH}{CD} + I \times \frac{EI}{DE}$.

Let A*bcd*E be the figure ABCDE inverted, in the manner already described. It may be conceived as a thread fastened at A and E, and loaded at *b*, *c*, and *d* with the weights which are really pressing on B, C, and D. It will arrange itself into such a form that all will be in equilibrio. We may discover this form by means of this single consideration, that any part *bc* of the thread is equally stretched throughout in the direction of its length. Let us therefore investigate the proportion between the weight β, which we suppose to be pulling the point *b* in the vertical direction $b\beta$, to the weight δ, which is pulling down the point *d* in a similar manner. It is evident, that since AE is a horizontal line, and the figures A*bcd*E and ABCDE equal and similar, the lines B*b*, C*c*, D*d*, are vertical. Take *bf* to represent the weight hanging at *b*. By stretching the threads *b*A and *bc* it is set in opposition to the contractile powers of the threads, acting in the directions *b*A and *bc*, and it is in immediate equilibrio with the equivalent of these two contractile forces. Therefore make *bg* equal to *bf*, and make it the diagonal of a parallelogram *hbig*. It is evident that *bh*, *bi*, are the forces exerted by the threads *b*A, *bc*. Then, seeing that the thread *bc* is equally stretched in both directions, make *ck* equal to *bi*; *ck* is the contractile force which is excited at *c* by the weight which is hanging there. Draw *kl* parallel to *cd*, and *lm* parallel to *bc*. The force *lc* is the equivalent of the contractile forces *ck*, *cm*, and is therefore equal and opposite to the force of gravity acting at C. In like manner, make $dn = cm$, and complete the parallelogram *ndpo*, having the vertical line *od* for its diagonal. Then *dn* and *dp* are the contractile forces excited at *d*, and the weight hanging there must be equal to *od*.

Therefore, the load at *b* is to the load at *d* as *bg* to *do*. But we have seen that the compressing forces at B, C, D may be substituted for the extending forces at *b*, *c*, *d*. Therefore the weights at B, C, D which produce the compressions, are equal to the weights at *b*, *c*, *d* which produce the extensions. Therefore

$$bg : do = F \times \frac{AF}{AB} + G \times \frac{CG}{BC} : H \times \frac{CH}{CD} + I \times \frac{EI}{DE}.$$

Let us inquire what relation there is between this proportion of the loads upon the joints at B and D, and the angles which the rafters make at these joints with each other, and with the horizon or the plumb-lines. Produce AB till it cut the vertical C*c* in Q; then draw BR parallel to CD, and BS parallel to DE. The similarity of the figures ABCDE and A*bcd*E, and the similarity of their position with respect to the horizontal and plumb lines, show, without any further demonstration, that the triangles QCB and *gbi* are similar, and that $QB : BC = gi : ib = hb : ib$. Therefore QB is to BC as the contractile force exerted by the thread A*b* to that exerted by *bc*; and therefore QB is to BC as the compression on BA to the compression on BC.[1] Then, because *bi* is equal to *ck*, and the triangles CBR and *ckl* are similar, $CB : BR = ck : kl = ck : cm$, and CB is to BR as the compression on CB to the compression on CD. And, in like manner, because $cm = dn$, we have BR to BS as the compression on DC to the compression on DE. Also $BR : RS = nd : do$, that is, as the compression on DC to the load on D. Finally, combining all these ratios,

$$QC : CB = gb : bi = gb : kc,$$
$$CB : BR = kc : kl = kc : dn,$$
$$BR : BS = nd : no = dn : no,$$
$$BS : RS = no : do = no : do, \text{ we have finally}$$
$$QC : RS = gb : od = \text{load at B} : \text{load at D}.$$

Now

$$QC : BC = \text{sin. } QBC : \text{sin. } BQC = \text{sin. } ABC : \text{sin. } ABb,$$
$$BC : BR = \text{sin. } BRC : \text{sin. } BCR = \text{sin. } CDd : \text{sin. } bBC,$$
$$BR : RS = \text{sin. } BSR : \text{sin. } RBS = \text{sin. } dDE : \text{sin. } CDE.$$

Therefore

$$QC : RS = \text{sin. } ABC \text{ sin. } CDd \text{ sin. } dDE : \text{sin. } CDE \text{ sin. } ABb \text{ sin. } bBC.$$

Or

$$QC : RS = \frac{\text{sin. } ABC}{\text{sin. } ABb \text{ sin. } CBb} : \frac{\text{sin. } CDE}{\text{sin. } dDC \text{ sin. } dDE}.$$

That is, the loads on the different joints are as the sines of the angles at these joints directly, and as the products of the sines of the angles which the rafters make with the plumb-lines inversely.

Or, the loads are as the sines of the angles of the joints directly, and as the products of the cosines of the angles of elevation of the rafters inversely.

Or, the loads at the joints are as the sines of the angles at the joints, and as the products of the secants of the angles of elevation of the rafters jointly; for the secants of angles are inversely as the cosines.

Draw the horizontal line BT. It is evident, that if this be considered as the radius of a circle, the lines BQ, BC, BR, BS are the secants of the angles which these lines

---

[1] This proportion might have been shown directly without any use of the inverted figure, or consideration of contractile forces; but the substitution gives distinct notions of the mode of acting, even to persons not much conversant in such disquisitions; and we wish to make it familiar to the mind, because it gives an easy solution of the most complicated problems, and furnishes the practical carpenter, who has little science, with solutions of the most difficult cases by experiment. A festoon, as we called it, may easily be made; and we are certain that the forms into which it will arrange itself are models of perfect frames.

Roof.

make with the horizon; and they are also as the thrusts of those rafters to which they are parallel. Therefore, the thrust which any rafter makes in its own direction is as the secant of its elevation.

The horizontal thrust is the same at all the angles. For $i\iota = k\varkappa = m\mu = n\nu = p\pi$. Therefore both walls are equally pressed out by the weight of the roof. We can find its quantity by comparing it with the load on one of the joints. Thus, QC : CB = sin. ABC : sin. AB*b*

BC : BT = rad. : sin. BCT = rad. : sin. CB*b*.

Therefore, QC : BT = rad. × sin. ABC : sin. *b*BA × sin. *b*BC.

e length the ms de- ds on weights he an- s.

It deserves remark, that the lengths of the beams do not affect either the proportion of the load at the different joints, or the position of the rafters. This depends merely on the weights at the angles. If a change of length affects the weight, it indeed affects the form also; and this is generally the case. For it seldom happens, indeed it never should happen, that the weight on rafters of longer bearing is not greater. The covering alone increases nearly in the proportion of the length of the rafter.

If the proportion of the weights at B, C, and D is given, as also the position of any two of the lines, the position of all the rest is determined. If the horizontal distances between the angles are all equal, the forces on the different angles are proportional to the verticals drawn on the lines through these angles from the adjoining angle, and the thrusts from the adjoining angles are as the lines which connect them. If the rafters themselves are of equal lengths, the weights at the different angles are as these verticals and as the secants of the angles of elevation of the rafters jointly.

ctical rences.

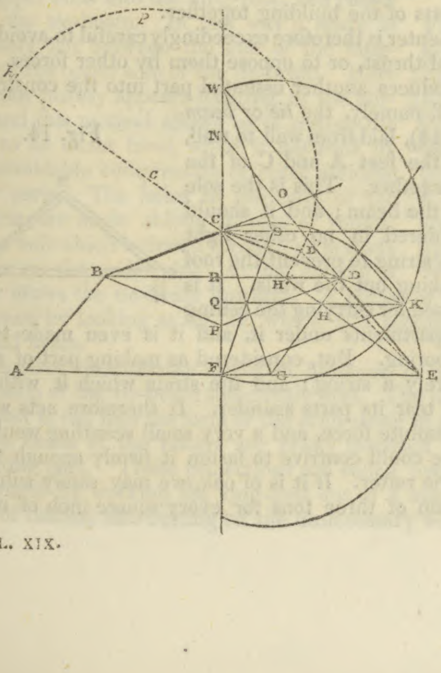
This proposition is very fruitful in its practical consequences. It is easy to perceive that it contains the whole theory of the construction of arches; for each stone of an arch may be considered as one of the rafters of this piece of carpentry, since all is kept up by its mere equilibrium. We may have an opportunity in a future article of exhibiting some very elegant and simple solutions of the most difficult cases of this important problem; and we now proceed to make use of the knowledge we have acquired for the construction of roofs.

T deter- e the form kirb- f.

We mentioned by the by a problem which is not unfrequent in practice, to determine the best form of a kirb-roof. M. Couplet of the Royal Academy of Paris has given a solution of it in an elaborate memoir in 1726, occupying several lemmas and theorems.

Let AE (fig. 11) be the width, and CF the height; it is required to construct a roof ABCDE, whose rafters AB, BC, CD, DE, are all equal, and which shall be in equilibrio.

Fig. 11.



Roof.

Draw CE, and bisect it perpendicularly in H by the line DHG, cutting the horizontal line AE in G. About the centre G, with the distance GE, describe the circle EKC. It must pass through C, because CH is equal to HE and the angles at H are equal. Draw HK parallel to FE, cutting the circumference in K; draw CK, cutting GH in D; and join CD, ED. These lines are the rafters of half of the roof required.

We prove this by showing that the loads at the angles C and D are equal; for this is the proportion which results from the equality of the rafters, and the extent of surface of the uniform roofing which they are supposed to support. Therefore produce ED till it meet the vertical FC in N; and having made the side CBA similar to CDE, complete the parallelogram BCDP, and draw DB, which will bisect CP in R, as the horizontal line KH bisects CF in Q. Draw KF, which is evidently parallel to DP. Make CS perpendicular to CF, and equal to FG; and about S, with the radius SF, describe the circle FKW. It must pass through K, because SF is equal to CG, and CQ = QF. Draw WK, WS, and produce BC, cutting ND in O.

The angle WKF at the circumference is one half of the angle WSF at the centre, and is therefore equal to WSC or CGF. It is therefore double of the angle CEF or ECS. But ECS is equal to ECD and DCS, and ECD is one half of NDC, and DCS is one half of DCO or CDP. Therefore the angle WKF is equal to NDP, and WK is parallel to ND, and CF is to CW as CP to CN; and CN is equal to CP. But it has been shown above that CN and CP are as the loads upon D and C. These are therefore equal, and the frame ABCDE is in equilibrio.

A comparison of this solution with that of M. Couplet will show its great advantage in respect of simplicity and perspicuity; and the intelligent reader can easily adapt the construction to any proportion between the rafters AB and BC, which other circumstances, such as garret-rooms, &c. may render convenient. The construction must be such that NC may be to CP as CD to $\frac{\mathrm{CD}+\mathrm{DE}}{2}$. Whatever proportion of AB to BC is assumed, the point D′ will be found in the circumference of a semicircle H′D′*h*′, whose centre is in the line CE, and having AB : BC = CH′ : H′E = *ch*′ : *h*′E. The rest of the construction is simple.

In buildings which are roofed with slate, tile, or shingles, the circumstance which is most likely to limit the construction is the slope of the upper rafters CB, CD. This must be sufficient to prevent the penetration of rain, and the stripping by the winds. The only circumstance left in our choice in this case is the proportion of the rafters AB and BC. Nothing is easier than making NC to CP in any desired proportion when the angle BCD is given.

The truss for a roof should always be in equilibrio.

We need not repeat that it is always a desirable thing to form a truss for a roof in such a manner that it shall be in equilibrio. When this is done, the whole force of the struts and braces which are added to it is employed in preserving this form, and no part is expended in unnecessary strains. For we must now observe, that the equilibrium of which we have been treating is always of that kind which we call the tottering, and the roof requires stays, braces, or hanging timbers, to give it stiffness, or keep it in shape. We have also said enough to enable any reader acquainted with the most elementary geometry and mechanics, to compute the transverse strains and the thrusts to which the component parts of all roofs are exposed.

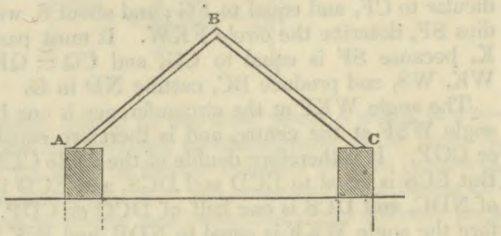
General maxims for all roofs

It only remains now to show the general maxims by which all roofs must be constructed, and the circumstances which determine their excellence. In doing this we shall be exceedingly brief, and almost content ourselves with exhibiting the principal forms, of which the endless variety of roofs are only slight modifications. We shall not trouble the reader with any account of such roofs as receive part of their support from the interior walls, but confine ourselves to the more difficult problem of throwing a roof over a wide building, without any intermediate support; because when such roofs are constructed in the best manner, that is, deriving the greatest possible strength from the materials employed, the best construction of the others is necessarily included. For all such roofs as rest upon the middle walls are roofs of smaller bearing. The only exception deserving notice is the roofs of churches, which have aisles separated from the nave by columns. The roof must rise on these. But if it is of an arched form internally, the horizontal thrusts must be nicely balanced, that they may not push the columns aside.

Simplest notion of a roof.

The simplest notion of a roof-frame is, that it consists of two rafters AB and BC (fig. 12), meeting in the ridge.

Fig. 12.

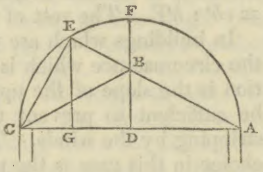


But even this simple form is susceptible of better and worse. We have already seen, that when the weight of a square yard of covering is given, a steeper roof requires stronger rafters, and that when the scantling of the timbers is also given, the relative strength of a rafter is inversely as its length.

Best form of rafters.

But there is now another circumstance to be taken into the account, viz. the support which one rafter leg gives to the other. The best form of a rafter will therefore be that in which the relative strength of the legs, and their mutual support, give the greatest product. Mr Muller, in his Military Engineer, gives a determination of the best pitch of a roof, which has considerable ingenuity, and has been copied into many books of military education both in this island and on the continent. Describe on the width AC (fig. 13) the semicircle AFC, and bisect it by the radius FD. Produce the rafter AB to the circumference in E, join EC, and draw the perpendicular EG. Now AB : AD = AC : AE, and $AE = \frac{AD \times AC}{AB}$, and AE is inversely as AB, and may therefore represent its strength in relation to the weight actually lying on it. Also the support which CB gives to AB is as CE, because CE is perpendicular to AB. Therefore the form which renders AE × EC a maximum seems to be that which has the greatest strength. But AC : AE = EC : EG, and $EG = \frac{AE \times EC}{AC}$, and is therefore proportional to AE × EC. Now EG is a maximum when B is in F, and a square pitch is in this respect the strongest. But it is very doubtful whether this construction is deduced from just principles. There is another strain to which the leg AB is exposed, which is not taken into the account. This arises from the curvature which it unavoidably acquires by the transverse pressure of its load. In this state it is pressed in its own direction by the abutment and load of the other leg. The relation between this strain and the resistance of the piece is not very distinctly known. Euler has given a dissertation on this subject, which is of great importance, because it affects posts and pillars of all kinds; and it is very well known that a post of ten feet long and six inches square will bear with great safety a weight which would crush a post of the same scantling and twenty feet long in a minute; but his determination has not been acquiesced in by the first mathematicians. Now it is in relation to these two strains that the strength of the rafter should be adjusted. The firmness of the support given by the other leg is of no consequence, if its own strength is inferior to the strain. The force which tends to crush the leg AB, by compressing it in its curved state, is to its weight as AB to BD, as is easily seen by the composition of forces; and its incurvation by this force has a relation to it, which is of intricate determination. It is contained in the properties demonstrated by Bernoulli of the elastic curve. This determination also includes the relation between the curvature and the length of the piece. But the whole of this seemingly simple problem is of much more difficult investigation than Mr Muller was aware of; and his rules for the pitch of a roof, and for the sally of a dock-gate, which depends on the same principles, are of no value. He is, however, the first author who attempted to solve either of these problems on mechanical principles susceptible of precise reasoning. Belidor's solutions, in his *Architecture Hydraulique*, are below notice.

Fig. 13.



Reasons of economy have made carpenters prefer a low pitch; and although this does diminish the support given by the opposite leg faster than it increases the relative strength of the other, it is not of material consequence, because the strength remaining in the opposite leg is still very great; for the supporting leg is acting against compression, in which case it is vastly stronger than the supported leg acting against a transverse strain.

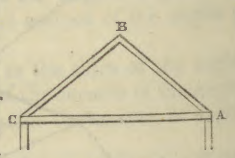
Thrust on the walls.

But a roof of this simplicity will not do in most cases. There is no notice taken, in its construction, of the thrust which it exerts on the walls. Now this is the strain which is the most hazardous of all. Our ordinary walls, instead of being able to resist any considerable strain pressing them outwards, require, in general, some ties to keep them on foot. When a person thinks of the thinness and height of the walls of even a strong house, he will be surprised that they are not blown down by any strong puff of wind. A wall three feet thick, and sixty feet high, could not withstand a wind blowing at the rate of thirty feet per second (in which case it acts with a force considerably exceeding two pounds on every square foot), if it were not stiffened by cross walls, joists, and roof, which all help to tie the different parts of the building together.

How this is avoided.

A carpenter is therefore exceedingly careful to avoid every horizontal thrust, or to oppose them by other forces. And this introduces another essential part into the construction of a roof, namely, the *tie* or *beam* AC (fig. 14), laid from wall to wall, binding the feet A and C of the rafters together. This is the sole office of the beam; and it should be considered in no other light than as a string to prevent the roof from pushing out the walls. It is indeed used for carrying the ceiling of the apartments under it, and it is even made to support a flooring. But, considered as making part of a roof, it is merely a string; and the strain which it withstands tends to tear its parts asunder. It therefore acts with its whole absolute force, and a very small scantling would suffice if we could contrive to fasten it firmly enough to the foot of the rafter. If it is of oak, we may safely subject it to a strain of three tons for every square inch of its sec-

Fig. 14.



tion. And fir will safely bear a strain of two tons for every square inch. But we are obliged to give the tie-beam much larger dimensions, that we may be able to connect it with the foot of the rafter by a mortise and tenon. Iron straps are also frequently added. By attending to this office of the tie-beam, the judicious carpenter is directed to the proper form of the mortise and tenon, and of the strap. We shall consider both of these in a proper place, after we become acquainted with the various strains at the joints of a roof.

These large dimensions of the tie-beam allow us to load it with the ceilings without any risk, and even to lay floors on it with moderation and caution. But when it has a great bearing or span, it is very apt to bend downwards in the middle, or, as the workmen term it, to sway or swag; and it requires a support. The question is, where to find this support. What fixed points can we find with which to connect the middle of the tie-beam? Some ingenious carpenter thought of suspending it from the ridge by a piece of timber BD (fig. 15), called by our carpenters the *king-post.* It must be acknowledged, that there was very great ingenuity in this thought. It was also perfectly just. For the weight of the rafters BA, BC tends to make them fly out at the foot. This is prevented by the tie-beam, and this excites a pressure, by which they tend to compress each other. Suppose them without weight, and that a great weight is laid on the ridge B. This can be supported only by the abutting of the rafters in their own directions AB and CB, and the weight tends to compress them in the opposite directions, and, through their intervention, to stretch the tie-beam. If neither the rafters can be compressed, nor the tie-beam stretched, it is plain that the triangle ABC must retain its shape, and that B becomes a fixed point very proper to be used as a point of suspension. To this point, therefore, is the tie-beam suspended by means of the king-post. A common spectator unacquainted with carpentry views it very differently, and the tie-beam appears to him to carry the roof. The king-post appears a pillar resting on the beam, whereas it is really a string; and an iron rod of one sixteenth of the size would have done just as well. The king-post is sometimes mortised into the tie-beam, and pins put through the joint, which gives it more the look of a pillar with the roof resting on it. This does well enough in many cases. But the best method is to connect them by an iron strap like a stirrup, which is bolted at its upper ends into the king-post, and passes round the tie-beam. In this way a space is commonly left between the end of the king-post and the upper side of the tie-beam. Here the beam plainly appears hanging in the stirrup; and this method allows us to restore the beam to an exact level, when it has sunk by the unavoidable compression or other yielding of the parts. The holes in the sides of the iron strap are made oblong instead of round; and the bolt which is drawn through all is made to taper on the under side; so that driving it farther draws the tie-beam upwards. A notion of this may be formed by looking at fig. 16, which is a section of that post and beam.

Fig. 15.

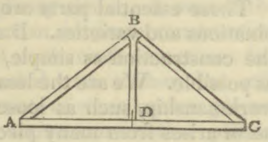


Fig. 16.

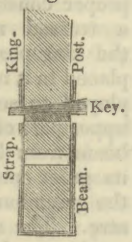
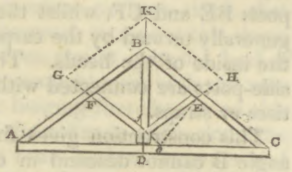


It requires considerable attention, however, to make this suspension of the tie-beam sufficiently firm. The top of the king-post is cut into the form of the arch-stone of a bridge, and the heads of the rafters are firmly mortised into this projecting part. These projections are called joggles, and are formed by working the king-post out of a much larger piece of timber, and cutting off the unnecessary wood from the two sides; and, lest all this should not be sufficient, it is usual in great works to add an iron plate or strap of three branches, which are bolted into the heads of the king-post and rafters.

The rafters, though not so long as the beam, seem to stand as much in need of something to prevent their bending, for they carry the weight of the covering. This cannot be done by suspension, for we have no fixed points above them. But we have now got a very firm point of support at the foot of the king-post. *Braces,* or rather *struts,* ED, FD (fig. 17), are put under the middle of the rafters, where they are slightly mortised, and their lower ends are firmly mortised into joggles formed on the foot of the king-post. As these braces are very powerful in their resistance to compression, and the king-post equally so to resist extension, the points E and F may be considered as fixed; and the rafters being thus reduced to half their former length, have now four times their former relative strength.

Fig. 17.

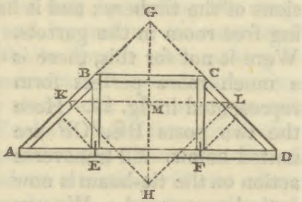


Construction of flat-topped roofs.

Roofs do not always consist of two sloping sides meeting in a ridge. They have sometimes a flat on the top, with two slopping sides. They are sometimes formed with a double slope, and are called *kirb* or *mansarde roofs.* They sometimes have a valley in the middle, and are then called M roofs. Such roofs require another piece, which may be called the *truss-beam,* because all such frames are called *trusses,* probably from the French word *trousse,* because such roofs are like portions of plain roofs *troussés* or shortened.

A flat-topped roof is thus constructed. Suppose the three rafters AB, BC, CD (fig. 18), of which AB and CD are equal, and BC horizontal. It is plain that they will be in equilibrio, and the roof have no tendency to go on either side. The tie-beam AD withstands the horizontal thrusts of the whole frame, and the two rafters AB and CD are each pressed in their own directions in consequence of their abutting with the middle rafter or truss-beam BC. It lies between them like the key-stone of an arch. They lean towards it, and it rests on them. The pressure which the truss-beam and its load excites on the two rafters is the very same as if the rafters were produced till they meet in G, and a weight were laid on these equal to that of BC and its load. If therefore the truss-beam is of a scantling sufficient for carrying its own load, and withstanding the compression from the two rafters, the roof will be equally strong, whilst it keeps its shape, as the plain roof AGD, furnished with the king-post and braces. We may conceive this another way. Suppose a plain roof AGD, without braces to support the middle B and C of the rafters. Then let a beam BC be put in between the rafters, abutting upon little notches cut in the rafters. It is evident that this must prevent the rafters from bending downwards, because the points B and C cannot descend, moving round the centres A and D, without shortening the distance BC between them. This cannot be without compressing the beam BC. It is plain that BC may be wedged in, or wedges driven in between its ends B and C and the notches in which it is lodged. These wedges may be driven in till they even force out the rafters GA and GD. Whenever this happens, all the mutual pressure of the heads of these rafters at G is taken away, and the parts GB and GC may be cut away, and the

Fig. 18.



roof ABCD will be as strong as the roof AGD furnished with the king-post and braces, because the truss-beam gives a support of the same kind at B and C as the brace would have done.

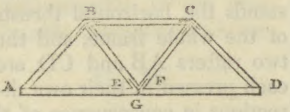
But this roof ABCD would have no firmness of shape. Any addition of weight on one side would destroy the equilibrium at the angle, would depress that angle, and would cause the opposite one to rise. To give it stiffness, it must either have ties or braces, or something partaking of the nature of both. The usual method of framing is to make the heads of the rafters abut on the joggles of two side-posts BE and CF, whilst the truss-beam, or strut as it is generally termed by the carpenters, is mortised square into the inside of the heads. The lower ends E and F of the side-posts are connected with the tie-beam either by mortises or straps.

This construction gives firmness to the frame; for the angle B cannot descend in consequence of any inequality of pressure, without forcing the other angle C to rise. This it cannot do, being held down by the post CF. And the same construction fortifies the tie-beam, which is now suspended at the points E and F from the points B and C, whose firmness we have just now shown.

They are not so strong as the plain roofs.

But although this roof may be made abundantly strong, it is not quite so strong as the plain roof AGD of the same scantling. The compression which BC must sustain in order to give the same support to the rafters at B and C that was given by braces properly placed, is considerably greater than the compression of the braces. And this strain is an addition to the transverse strain which BC gets from its own load. This form also necessarily exposes the tie-beam to cross strains. If BE is mortised into the tie-beam, then the strain which tends to depress the angle ABC presses on the tie-beam at E transversely, whilst a contrary strain acts on F, pulling it upwards. These strains, however, are small; and this construction is frequently used, being susceptible of sufficient strength, without much increase of the dimensions of the timbers; and it has the great advantage of giving free room in the garrets. Were it not for this, there is a much more perfect form represented in fig. 19. Here the two posts BE, CF are united below. All transverse action on the tie-beam is now entirely removed. We are almost disposed to say that this is the strongest roof of the same width and slope. For if the iron strap which connects the pieces BE, CF with the tie-beam have a large bolt G through it, confining it to one point of the beam, there are five points, A, B, C, D, G, which cannot change their places, and there is no transverse strain in any of the connections.

Fig. 19.



When the dimensions of the building are very great, so that the pieces AB, BC, CD, would be thought too weak for withstanding the cross strains, braces may be added as is expressed in fig. 18 by the dotted lines. The reader will observe, that it is not meant to leave the top flat externally; it must be raised a little in the middle, to shoot off the rain. But this must not be done by incurvating the beam BC. This would soon be crushed, and spring upwards. The slopes must be given by pieces of timber added above the strutting-beam.

Members of which the frame of a roof consists.

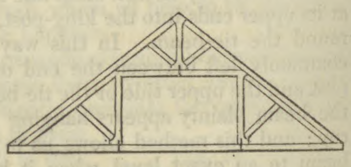
And thus we have completed a frame of a roof. It consists of these principal members: the rafters, which are immediately loaded with the covering; the tie-beam, which withstands the horizontal thrust by which the roof tends to fly out below and push out the walls; the king-posts, which hang from fixed points and serve to uphold the tie-beam, and also to afford other fixed points on which we may rest the braces which support the middle of the rafters; and, lastly, the truss or strutting-beam, which serves to give mutual abutment to the different parts which are at a distance from each other. The rafters, braces, and trusses are exposed to compression, and must therefore have not only cohesion, but stiffness. For if they bend, the prodigious compressions to which they are subjected would quickly crush them in this bended state. The tie-beams and king-posts, if performing no other office but supporting the roof, do not require stiffness; and their places might be supplied by ropes, or by rods of iron of one-tenth part of the section that even the smallest oak stretcher requires. These members require no greater dimensions than what is necessary for giving sufficient joints, and any more is a needless expense. All roofs, however complicated, consist of these essential parts; and if pieces of timber are to be seen which perform none of these offices, they must be pronounced useless, and they are frequently hurtful, by producing cross strains in some other piece. In a roof properly constructed there should be no such strains. All the timbers, excepting those which immediately carry the covering, should be either pushed or drawn in the direction of their length. And this is the rule by which a roof should always be examined.

They ar susceptil of numb less com nations varieties

These essential parts are susceptible of numberless combinations and varieties. But it is a prudent maxim to make the construction as simple, and consisting of as few parts, as possible. We are the less exposed to the imperfections of workmanship, such as loose joints, &c. Another essential harm arises from many pieces, by the compression and the shrinking of the timber in the cross direction of the fibres. The effect of this is equivalent to the shortening of the piece which abuts on the joint. This alters the proportions of the sides of the triangle on which the shape of the whole depends. Now, in a roof such as fig. 18, there is twice as much of this as in the plain pent-roof, because there are two posts. And when the direction of the abutting pieces is very oblique to the action of the load, a small shrinking permits a great change of shape. Thus, in a roof of what is called pediment pitch, where the rafters make an angle of thirty degrees with the horizon, half an inch compression of the king-post will produce a sagging of an inch, and occasion a great strain on the tie-beam, if the posts are mortised into it.

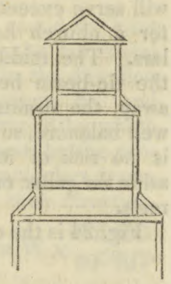
This method of including a truss within the rafters of a pent-roof is a very considerable addition to the art of carpentry. But to insure its full effect, it should always be executed with abutting rafters under the principal ones, abutting on joggles in the heads of the posts. Without this the strut-beam is hardly of any service. We would therefore recommend fig. 20 as a proper construction of a trussed roof; and the king-post which is placed in it may be employed to support the upper part of the rafters, and also for preventing the strut-beam from bending in their direction in consequence of its great compression. It will also give a suspension for the great burdens which are sometimes necessary in a theatre. The machinery has no other firm points to which it can be attached; and the portions of the single rafters which carry this king-post are but short, and therefore may be considerably loaded with safety.

Fig. 20.



We observe in the drawings which we sometimes have of Chinese buildings, that the trussing of roofs is understood by them Indeed they must be very experienced carpenters. We see wooden buildings run up to a great height, which can be supported only by such trussing. One of these is sketched in fig. 21. There are some very excellent specimens to be seen in the buildings at Deptford, belonging to the victualling-office, commonly called the *Red-house*, which were erected about the year 1788, and we believe are the performance of Mr James Arrow of the Board of Works, one of the most intelligent artists in this kingdom.

Fig. 21.



marks
ressed

enters.

Thus have we given an elementary, but a rational or scientific, account of this important part of the art of carpentry. It is such, that any practitioner, with the trouble of a little reflection, may always proceed with confidence, and without resting any part of his practice on the vague notions which habit may have given him of the strength and supports of timbers, and of their manner of acting. That these frequently mislead, is proved by the mutual criticisms which are frequently published by the rivals in the profession. They have frequently sagacity enough, for it seldom can be called science, to point out glaring blunders; and any person who will look at some of the performances of Mr Price, Mr Wyatt, Mr Arrow, and others of acknowledged reputation, will readily see them distinguishable from the works of inferior artists by simplicity alone. A man without principles is apt to consider an intricate construction as ingenious and effectual; and such roofs sometimes fail merely by being ingeniously loaded with timber, but still more frequently by the wrong action of some useless pieces, which produces strains that are transverse to other pieces, or which, by rendering some points too firm, cause them to be deserted by the rest in the general subsiding of the whole. Instances of this kind are pointed out by Price in his British Carpenter. Nothing shows the skill of a carpenter more than the distinctness with which he can foresee the changes of shape which must take place in a short time in every roof. A knowledge of this will often correct a construction which the mere mathematician thinks unexceptionable, because he does not reckon on the actual compression which must obtain, and imagines that his triangles, which sustain no cross strains, invariably retain their shape till the pieces break. The sagacity of the experienced carpenter is not, however, enough without science for perfecting the art. But when he knows how much a particular piece will yield to compression in one case, science will then tell him, and nothing but science can do it, what will be the compression of the same piece in another very different case. Thus he learns how far it will now yield, and then he proportions the parts so to each other, that when all have yielded according to their strains, the whole is of the shape he wished to produce, and every joint is in a state of firmness. It is here that we observe the greatest number of improprieties. The iron straps are frequently in positions not suited to the actual strain on them; and they are in a state of violent twist, which both tends strongly to break the straps, and to cripple the pieces which they surround.

In like manner, we frequently see joints or mortises in a state of violent strain on the tenons, or on the heels and shoulders. The joints were perhaps properly shaped for the primitive form of the truss; but by its settling, the bearing of the push is changed. The brace, for example, in a very low-pitched roof, comes to press with the upper part of the shoulder, and, acting as a powerful lever on the tenon, breaks it. In like manner, the lower end of the brace, which at first abutted firmly and squarely on the joggle of the king-post, now presses with one corner in prodigious force, and seldom fails to splinter off on that side. We cannot help recommending a maxim of M. Perronet, the celebrated hydraulic architect of France, as a golden rule, viz. to make all the shoulders of abutting pieces in the form of an arch of a circle, having the opposite end of the piece for its centre. Thus, in fig. 18, if the joggle-point B be of this form, having A for its centre, the sagging of the roof will make no partial bearing at the joint; for in the sagging of the roof the piece AB turns or bends round the centre A, and the counter-pressure of the joggle is still directed to A, as it ought to be. We have just now said *bends* round A. This is too frequently the case, and it is always very difficult to give the tenon and mortise in this place a true and invariable bearing. The rafter pushes in the direction BA, and the beam resists in the direction AD. The abutment should be perpendicular to neither of these, but in an intermediate direction, and it ought also to be of a curved shape. But the carpenters perhaps think that this would weaken the beam too much to give it this shape in the shoulder; they do not even aim at it in the heel of the tenon. The shoulder is commonly even with the surface of the beam. When the bearing therefore is on this shoulder, it causes the foot of the rafter to slide along the beam till the heel of the tenon bears against the outer end of the mortise (See Price's British Carpenter, plate C, fig. IK). This abutment is perpendicular to the beam in Price's book; but it is more generally pointed a little outwards below, to make it more secure against starting. The consequence of this construction is, that when the roof settles, the shoulder comes to bear at the inner end of the mortise, and it rises at the outer, and the tenon, taking hold of the wood beyond it, either tears it out or is itself broken. This joint therefore is seldom trusted to the strength of the mortise and tenon, and is usually secured by an iron strap, which lies obliquely to the beam, to which it is bolted by a large bolt quite through, and then embraces the outside of the rafter foot. This strap is very frequently not made sufficiently oblique, and we have seen some made almost square with the beam. When this is the case, it not only keeps the foot of the rafter from flying out, but it binds it down. In this case, the rafter acts as a powerful lever, whose fulcrum is in the inner angle of the shoulder, and then the strap never fails to cripple the rafter at the point. All this can be prevented only by making the strap very long and very oblique, and by making its outer end (the stirrup part) square with its length, and making a notch in the rafter foot to receive it. It cannot now cripple the rafter, for it will rise along with it, turning round the bolt at its inner end. We have been thus particular on this joint, because it is here that the ultimate strain of the whole roof is exerted, and its situation will not allow the excavation necessary for making it a good mortise and tenon.

Similar attention must be paid to some other straps, such as those which embrace the middle of the rafter, and connect it with the post or truss below it. We must attend to the change of shape produced by the sagging of the roof, and place the strap in such a manner as to yield to it by turning round its bolt, but so as not to become loose, and far less to make a fulcrum for any thing acting as a lever. The strains arising from such actions, in framings of carpentry which change their shape by sagging, are enormous, and nothing can resist them.

Mode of calculating strains or thrusts.

We shall close this part of the subject with a simple method, by which any carpenter, without mathematical science, may calculate with sufficient precision the strains or thrusts which are produced on any point of his work, whatever be the obliquity of the pieces.

Let it be required to find the horizontal thrust acting on the tie-beam AD of fig. 18. This will be the same as if the weight of the whole roof were laid at G on the two rafters GA and GD. Draw the vertical line GH. Then, having calculated the weight of the whole roof that is supported by this single frame ABCD, including the weight of the pieces AB, BC, CD, BE, CF themselves, take the number of pounds, tons, &c. which expresses it from any scale of equal parts, and set it from G to H. Draw HK, HL parallel to GD, GA, and draw the line KL, which will be horizontal when the two sides of the roof have the same slope. Then ML measured on the same scale will give the horizontal thrust, by which the strength of the tie-beam is to be regulated. GL will give the thrust which tends to crush the rafters, and LM will also give the force which tends to crush the strut-beam BC.

In like manner, to find the strain of the king-post BD of fig. 17, consider that each brace is pressed by half the weight of the roofing laid on BA or BC, and this pressure, or at least its hurtful effect, is diminished in the proportion of BA to DA, because the action of gravity is vertical, and the effect which we want to counteract by the braces is in a direction E*e* perpendicular to BA or BC. But as this is to be resisted by the brace *f*E acting in the direction *f*E, we must draw *fe* perpendicular to E*e*, and suppose the strain augmented in the proportion of E*e* to E*f*.

Having thus obtained in tons, pounds, or other measures, the strains which must be balanced at *f* by the cohesion of the king-post, take this measure from the scale of equal parts, and set it off in the directions of the braces to G and H, and complete the parallelogram G*f*HK; and *f*K measured on the same scale will be the strain on the king-post.

Strength of the truss.

The artist may then examine the strength of his truss upon this principle, that every square inch of oak will bear at an average 7000 pounds compressing or stretching it, and may be safely loaded with 3500 for any length of time; and that a square inch of fir will in like manner securely bear 2500. And, because straps are used to resist some of these strains, a square inch of well-wrought tough iron may be safely strained by 50,000 pounds. But the artist will always recollect, that we cannot have the same confidence in iron as in timber. The faults of this last are much more easily perceived; and when the timber is too weak, it gives us warning of its failure by yielding sensibly before it breaks. This is not the case with iron; and much of its service depends on the honesty of the blacksmith.

Sketch of some trussed roofs, &c.

In this way may any design of a roof be examined. We shall here give the reader a sketch of two or three trussed roofs, which have been executed in the chief varieties of circumstances which occur in common practice.

Fig. 22 is the roof of St Paul's Church, Covent Garden, London, the work of Inigo Jones. Its construction is singular. The roof extends to a considerable distance beyond the building, and the ends of the tie-beams support the Tuscan corniche, appearing like the mutules of the Doric order. Such a roof could not rest on the tie-beam. Inigo Jones has therefore supported it by a truss below it; and the height has allowed him to make this extremely strong with very little timber. It is accounted the highest roof of its width in London. But this was not difficult, by reason of the great height which its extreme width allowed him to employ without hurting the beauty of it by too high a pitch. The supports, however, are disposed with judgment.[1]

Fig. 22.

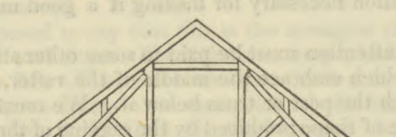

Fig. 23 is a kirb or mansarde roof by Price, and supposed to be of large dimensions, having braces to carry the middle of the rafters. It will serve exceedingly well for a church having pillars. The middle part of the tie-beam being taken away, the strains are very well balanced, so that there is no risk of its pushing aside the pillar on which it rests.

Fig. 23.

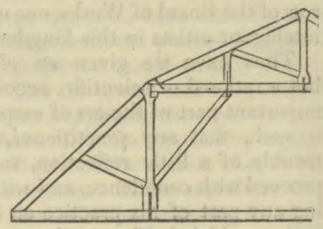

Fig. 24 is the celebrated roof of the Theatre of the University of Oxford, by Sir Christopher Wren. The span between the walls is 75 feet. This is accounted a very ingenious, and is a singular performance. The middle part of it is almost unchangeable in its form; but from this circumstance it does not distribute the horizontal thrust with the same regularity as the usual construction. The horizontal thrust on the tie-beam is about twice the weight of the roof, and is withstood by an iron strap below the beam, which stretches the whole width of the building in the form of a rope, making part of the ornament of the ceiling.

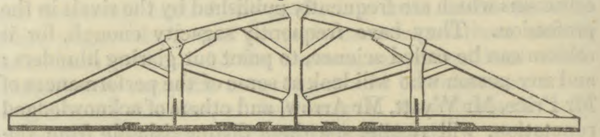
Fig. 24.



Cases in which th thrust ca not be di charged from the walls by the tie-beam.

In all the roofs which we have considered hitherto, the thrust is discharged entirely from the walls by the tie-beam. But this cannot always be done. We frequently want great elevation within, and arched ceilings. In such cases, it is a much more difficult matter to keep the walls free of all pressure outwards, and there are few buildings where it is completely done. Yet this is the greatest fault of a roof. We shall just point out the methods which may be most successfully adopted.

We have said that a tie-beam just performs the office of a string. We have said the same of the king-post. Now suppose two rafters AB, BC (fig. 25), moveable about the point B, and resting on the top of the walls. If the line BD be suspended from B, and the two lines DA, DC be fastened to the feet of the rafters, and if these lines be incapable of extension, it is plain that all thrust is removed from the walls as effectually as by a common tie-beam; and by shortening BD to B*d*, we gain a greater inside height, and more room for an arched ceiling. Now if we substitute a king-post BD (fig. 26), and two stretchers or hammer-beams DA, DC for the other strings, and connect them firmly by means of iron straps, we obtain our purpose.

Fig. 25.

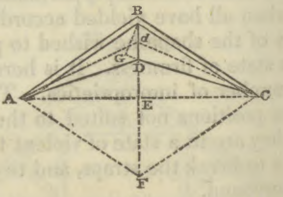


Fig. 26.

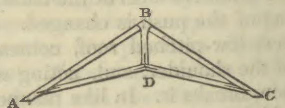


Let us compare this roof with a tie-beam roof in point of strain and strength. Recur to fig. 25, and complete the parallelogram ABCF, and draw the diagonals AC, BF, crossing in E. Draw BG perpendicular to CD. We have seen that the weight of the roof, which we may call W, is to the horizontal thrust at C as BF to EC; and if we express this thrust by T, we have $T = \frac{W \times EC}{BF}$. We may at present consider BC as a lever moveable round the joint B, and pulled at C in the direction EC by the horizontal thrust, and held back by the string pulling in the direction CD. Suppose that the forces in the directions EC and CD are in equilibrio, and let us find the force S by which the string CD is strained. These forces must, by the property of the lever, be inversely as the perpendiculars drawn from the centre of motion on the lines of their direction.

---

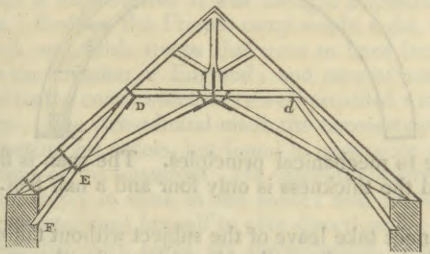
[1] This church was burnt down after the present article was written.

Therefore $BG : BE = T : S$, and $S = T \times \frac{BE}{BG} = W \times \frac{BE \cdot EC}{BF \cdot BG}$.

Therefore the strain upon each of the ties DA and DC is always greater than the horizontal thrust or the strain on a simple tie-beam. This would be no great inconvenience, because the smallest dimensions that we could give to these ties, so as to procure sufficient fixtures to the adjoining pieces, are always sufficient to withstand this strain. But although the same may be said of the iron straps which make the ultimate connections, there is always some hazard of imperfect work, cracks, or flaws, which are not perceived. We can judge with tolerable certainty of the soundness of a piece of timber, but cannot say so much of a piece of iron. Moreover, there is a prodigious strain excited on the king-post when BG is very short in comparison of BE, namely, the force compounded of the two strains S and S on the ties DA and DC.

But there is another defect from which the straight tie-beam is entirely free. All roofs settle a little. When this roof settles, and the points B and D descend, the legs BA, BC must spread further out, and thus a pressure outwards is excited on the walls. It is seldom therefore that this kind of roof can be executed in this simple form, and other contrivances are necessary for counteracting this supervening action on the walls. Fig. 27 is one of the best which we have seen, and is executed with great success in the circus or equestrian theatre (now, 1809, a concert-room) in Edinburgh, the width being sixty feet. The pieces EF and ED help to take off some of the weight, and by their greater uprightness they exert a smaller thrust on the walls. The beam D*d* is also a sort of truss-beam, having something of the same effect. Mr Price has given another very judicious one of this kind (British Carpenter, plate IK, fig. C), from which the tie-beam may be taken away, and there will remain very little thrust on the walls. Those which he has given in the following plate, K, are, in our opinion, very faulty. The whole strain in these last roofs tends to break the rafters and ties transversely, and the fixtures of the ties are also not well calculated to resist the strain to which the pieces are exposed. We hardly think that these roofs could be executed.

Fig. 27.



It is scarcely necessary to remind the reader, that in all that we have delivered on this subject, we have attended only to the construction of the principal rafters or trusses. In small buildings all the rafters are of one kind; but in great buildings the whole weight of the covering is made to rest on a few principal rafters, which are connected by beams placed horizontally, and either mortised into them or scarfed on them. These are called *purlins*. Small rafters are laid from purlin to purlin; and on these the laths for tiles, or the skirting-boards for slates, are nailed. Thus the covering does not immediately rest on the principal frames. This allows some more liberty in their construction, because the garrets can be so divided that the principal rafters shall be in the partitions, and the rest left unencumbered. This construction is so far analogous to that of floors which are constructed with girders, binding, and bridging joists.

It may appear presuming in us to question the propriety of this practice. There are situations in which it is unavoidable, as in the roofs of churches, which can be allowed to rest on some pillars. In other situations, where partition-walls intervene at a distance not too great for a stout purlin, no principal rafters are necessary, and the whole may be roofed with short rafters of very slender scantling. But in a great uniform roof, which has no intermediate supports, it requires at least some reasons for preferring this method of carcass-roofing to the simple method of making all the rafters alike. The method of carcass-roofing requires the selection of the greatest logs of timber, which are seldom of equal strength and soundness with thinner rafters. In these the outside planks can be taken off, and the best part alone worked up. It also exposes to all the defects of workmanship in the mortising of purlins, and the weakening of the rafters by this very mortising; and it brings an additional load of purlins and short rafters. A roof thus constructed may surely be compared with a floor of similar construction. Here there is not a shadow of doubt, that if the girders were sawed into planks, and these planks laid as joists sufficiently near for carrying the flooring boards, they will have the same strength as before, except so much as is taken out of the timber by the saw. This will not amount to one-tenth part of the timber in the binding, bridging, and ceiling joists, which are an additional load, and all the mortises and other joinings are so many diminutions of the strength of the girders; and as no part of a carpenter's work requires more skill and accuracy of execution, we are exposed to many chances of imperfection. But, not to rest on these considerations, however reasonable they may appear, we shall relate an experiment made by one on whose judgment and exactness we can depend.

Confirmed by experiment.

Two models of floors were made, eighteen inches square, of the finest uniform deal, which had been long seasoned. The one consisted of simple joists, and the other was framed with girders, binding, bridging, and ceiling joists. The plain joists of the one contained the same quantity of timber with the girders alone of the other, and both were made by a most accurate workman. They were placed in wooden trunks eighteen inches square within, and rested on a strong projection on the inside. Small shot was gradually poured in upon the floors, so as to spread uniformly over them. The plain joisted floor broke down with 487 pounds, and the carcass floor with 327. The first broke without giving any warning, and the other gave a violent crack when 294 pounds had been poured in. A trial had been made before, and the loads were 341 and 482; but the models having been made by a less accurate hand, it was not thought a fair specimen of the strength which might be given to a carcass floor.

The only argument of weight which we can recollect in favour of the compound construction of roofs is, that the plain method would prodigiously increase the quantity of work, would admit nothing but long timber, which would greatly add to the expense, and would make the garrets a mere thicket of planks. We admit this in its full force;

but we continue to be of the opinion that plain roofs are greatly superior in point of strength, and therefore should be adopted in cases where the main difficulty is to insure this necessary circumstance.

Of the roofs put on round buildings.

It would appear very neglectful to omit an account of the roofs put on round buildings, such as domes, cupolas, and the like. They appear to be the most difficult tasks in the carpenter's art. But the difficulty lies entirely in the mode of framing, or what the French call the *trait de charpenterie*. The view which we are taking of the subject, as a part of mechanical science, has little connection with this. It is plain, that whatever form of a truss is excellent in a square building, must be equally so as one of the frames of a round one; and the only difficulty is how to manage their mutual intersections at the top. Some of them must be discontinued before they reach that length, and common sense will teach us to cut them short alternately, and always leave as many, that they may stand equally thick as at their first springing from the base of the dome. Thus the length of the purlins, which reach from truss to truss, will never be too great.

The truth is, that a round building which gathers in at top, like a glass-house, a potter's kiln, or a spire steeple, instead of being the most difficult to erect with stability, is of all others the easiest. Nothing can show this more forcibly than daily practice, where they are run up without centres and without scaffoldings; and it requires gross blunders indeed in the choice of their outline to put them in much danger of falling from a want of equilibrium. In like manner, a dome of carpentry can hardly fall, give it what shape or what construction you will. It *cannot* fall, unless some part of it flies out at the bottom. An iron hoop round it, or straps at the joinings of the trusses and purlins, which make an equivalent to a hoop, will effectually secure it. And as beauty requires that a dome shall spring almost perpendicularly from the wall, it is evident that there is hardly any thrust to force out the walls. The only part where this is to be guarded against is where the tangent is inclined about forty or fifty degrees to the horizon. Here it will be proper to make a course of firm horizontal joinings.

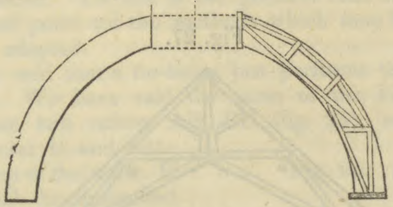
We doubt not but that domes of carpentry will now be raised of great extent. The Halle du Bled at Paris, of two hundred feet in diameter, was the invention of an intelligent carpenter, the Sieur Moulineau. He was not by any means a man of science, but had much more mechanical knowledge than artisans usually have, and was convinced that a very thin shell of timber might not only be so shaped as to be nearly in equilibrio, but that, if hooped or firmly connected horizontally, it would have all the stiffness that was necessary; and he presented his project to the magistracy of Paris. The grandeur of it pleased them, but they doubted of its possibility. Being a great public work, they prevailed on the Academy of Sciences to consider it. The members who were competent judges were instantly struck with the justness of M. Moulineau's principles, and astonished that a thing so plain had not been long familiar to every house-carpenter. It quickly became an universal topic of conversation, dispute, and cabal, in the polite circles of Paris. But the academy having given a very favourable report of their opinion, the project was immediately carried into execution, and soon completed; and now stands as one of the great exhibitions of Paris.

The construction of this dome is the simplest thing that can be imagined. The circular ribs which compose it consist of planks nine feet long, thirteen inches broad, and three inches thick; and each rib consists of three of these planks bolted together in such a manner that two points meet. A rib is begun, for instance, with a plank of three feet long standing between one of six feet and another of nine; and this is continued to the head of it. No machinery was necessary for carrying up such small pieces, and the whole went up like a piece of bricklayer's work. At various distances these ribs were connected horizontally by purlins and iron straps, which made so many hoops to the whole. When the work had reached such a height that the distance of the ribs was two thirds of the original distance, every third rib was discontinued, and the space was left open and glazed. When carried so much higher that the distance of the ribs is one third of the original distance, every second rib, now consisting of two ribs very near each other, is in like manner discontinued, and the void is glazed. A little above this the heads of the ribs are framed into a circular ring of timber, which forms a wide opening in the middle; over which is a glazed canopy or umbrella, with an opening between it and the dome for allowing the heated air to get out. All who have seen this dome say that it is the most beautiful and magnificent object they have ever beheld.

The only difficulty which occurs in the construction of wooden domes is when they are unequally loaded, by carrying a heavy lanthorn or cupola in the middle. In such a case, if the dome were a mere shell, it would be crushed in at the top, or the action of the wind on the lanthorn might tear it out of its place. Such a dome must therefore consist of trussed frames. Mr Price has given a very good one in his plate OP, though much stronger in the trusses than there was any occasion for. This causes a great loss of room, and throws the lights of the lanthorn too far up. It is evidently copied from Sir Christopher Wren's dome of St Paul's Church in London; a model of propriety in its particular situation, but by no means a general model of a wooden dome. It rests on the brick cone within it; and Sir Christopher has very ingeniously made use of it for stiffening this cone, as any intelligent person will perceive by attending to its construction.

Fig. 28 presents a dome executed in the Register Office in Edinburgh by James and Robert Adam, and is very agreeable to mechanical principles. The span is fifty feet clear, and the thickness is only four and a half feet.

Fig. 28.

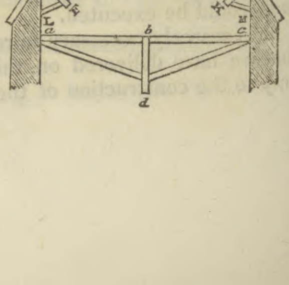


Furthe remark Norma roofs.

We cannot take leave of the subject without taking some notice of what we have already spoken of with commendation by the name of *Norman roofs*. We called them *Norman*, because they were frequently executed by that people soon after their establishment in Italy and other parts of the south of Europe, and became the prevailing taste in all the great baronial castles. Their architects were rivals to the Saracens and Moors, who about that time built many Christian churches; and the architecture which we now call Gothic seems to have arisen from their joint labours.

The principle of a Norman roof is extremely simple. The rafters all abutted on joggled king-posts AF, BG, CH, &c. (fig. 29), and braces or ties were then disposed in the intervals. In the middle of the roof HB and HD are evidently ties in a state of extension, whilst the post CH is compressed by them. Towards the walls on each side,

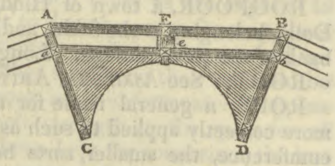
Fig. 29.



as between B and F, and between F and L, they are braces, and compressed. The ends of the posts were generally ornamented with knots of flowers, embossed globes, and the like, and the whole texture of the truss was exhibited and dressed out.

This construction admits of employing very short timbers; and this very circumstance gives greater strength to the truss, because the angle which the brace or tie makes with the rafter is more open. We may also perceive that all thrust may be taken off the walls. If the pieces AF, BF, LF, be removed, all the remaining diagonal pieces act as ties, and the pieces directed to the centre act as struts; and it may also be observed, that the principle will apply equally to a straight or flat roof or to a floor. A floor such as *abc*, having the joint in two pieces *ab*, *bc*, with a strut *bd*, and two ties, will require a much greater weight to break it than if it had a continued joist *ac* of the same scantling. And, lastly, a piece of timber acting as a tie is much stronger than the same piece acting as a strut; for in the latter situation it is exposed to bending, and when bent it is much less able to withstand a very great strain. It must be acknowledged, however, that this advantage is balanced by the great inferiority of the joints in point of strength. The joint of a tie depends wholly on the pins; and for this reason they are never used in heavy works without strapping the joints with iron. In the roofs we are now describing the diagonal pieces of the middle part only act purely as ties, whilst those towards the sides act as struts or braces. Indeed they are seldom of so very simple construction as we have described, and are more generally constructed like the sketch in fig. 30, having two sets of rafters AB, *ab*, and the angles are filled up with thin planks, which give great stiffness and strength. They have also a double set of purlins, which connect the different trusses. The roof being thus divided into squares, other purlins run between the middle points E of the rafters. The rafter is supported at E by a check put between it and the under rafter. The middle point of each square of the roof is supported and stiffened by four braces, one of which springs from *e*, and its opposite from the similar part of the adjoining truss. The other two braces spring from the middle points of the lower purlins, which go horizontally from *a* and *b* to the next truss, and are supported by planks in the same manner as the rafters. By this contrivance the whole becomes very stiff and strong. (B. B. B.)

Fig. 30.



ROOK. See ORNITHOLOGY.

ROOKE, SIR GEORGE, a gallant naval commander, was born of an ancient and honourable family in Kent in 1650. His merit raised him by regular steps to be vice-admiral of the blue, in which station he served in the battle of La Hogue, on the 22d of May 1692, when it was owing to his vigorous behaviour that the last stroke was given on that important day, which threw the French entirely into confusion. But the next day he obtained still more glory, for he had orders to go into La Hogue, and burn the enemy's ships as they lay there. There were thirteen large men of war, which had crowded as far up as possible; and the transports, tenders, and ammunition ships, were disposed in such a manner that it was thought impossible to burn them. Besides, the French camp was in sight, with all the French and Irish troops that were to have been employed in the invasion of England; and several batteries were raised on the coast, which were well provided with heavy artillery. The vice-admiral made the necessary preparations for obeying his orders, but found it impossible to carry in the ships of his squadron. He therefore ordered his light frigates to ply in close to the shore; and having manned all his boats, went himself to give directions for the attack, burned that very night six three-decked ships, and the next day six more, from seventy-six to sixty guns, together with most of the transports and ammunition vessels; and this under the fire of all the batteries just mentioned, and in sight of all the French and Irish troops. Yet this bold action cost the lives of no more than ten men. The vice-admiral's behaviour on this occasion appeared to King William so great, that having no opportunity at that time of promoting him, he settled a pension of L.1000 per annum on him for life; and afterwards going to Portsmouth to view the fleet, went on board Admiral Rooke's ship, dined with him, and then conferred on him the honour of knighthood, having a little before made him vice-admiral of the red.

In consequence of other services, he was in 1694 raised to the rank of admiral of the blue; towards the close of the next year he became admiral of the white, and was also appointed admiral and commander in chief in the Mediterranean.

During King William's reign, Sir George was twice elected member for Portsmouth; and upon the accession of Queen Anne in 1702, he was constituted vice-admiral and lieutenant of the admiralty of England, as also lieutenant of the fleets and seas of this kingdom. Upon the declaration of war against France, he was ordered to command a fleet sent against Cadiz, the Duke of Ormond having the command of the land forces. On his passage home, having received an account that the galleons, under the escort of a strong French squadron, had got into the harbour of Vigo, he resolved to attack them; and on the 11th of October he came before the harbour of Rondondello, where the French commander had neglected nothing necessary for putting the place in the best posture of defence. But notwithstanding this, a detachment of fifteen English and ten Dutch men of war, of the line of battle, with all the fire-ships, were ordered in; the frigates and bomb-vessels followed; the great ships moved after them, and the army landed near Rondondello. The whole service was performed under Sir George's directions, with admirable conduct and bravery; for all the ships were destroyed or taken, prodigious damage was done to the enemy, and vast wealth was acquired by the allies. For this action Sir George received the thanks of the House of Commons, a day of thanksgiving was appointed both by the queen and the states-general, and Sir George was appointed to a seat in the privy-council. Yet notwithstanding this, the House of Lords resolved to inquire into his conduct at Cadiz. But he so fully justified himself, that a vote was passed approving his behaviour.

In the spring of the year 1704, Sir George commanded the ships of war which conveyed King Charles III. of Spain to Lisbon. In July he attacked Gibraltar, when, by the bravery of the English seamen, the place was taken on the 24th, though the town was extremely strong, well furnished with ammunition, and had a hundred guns mounted, all facing the sea and the narrow passes to the land; an action which was conceived and executed in less than a week, though it has since endured sieges of many months' continuance, and more than once baffled the united forces of France and Spain. This brave officer being at last obliged, by the prevalence of party spirit, to quit the service of his country, retired to his seat in Kent, where he spent the remainder of his days as a private gentleman. He was thrice married; and by his second lady, Mrs Luttrel, left one son.

He died on the 24th of January 1708, in his fifty-eighth year.

ROONAY, a town of Bengal, in the district of Birbhoom, which formerly possessed a small fort that commanded the high road. Long. 87. 0. E. Lat 24. 26. N.

ROOT. See ALGEBRA, ARITHMETIC, and EQUATIONS.

ROPE, a general name for all kinds of cordage, but more correctly applied to such as is above one inch in circumference, the smaller sorts being distinguished by the names of twines, cords, and lines.

The art of twisting into lines and ropes various materials, such as thongs of animal hide, the hairs of animals, tough grasses, and vegetable fibres, is of remote antiquity, and has existed even among the rudest people.

The tarabita or rope-bridge of the Peruvians, and the lasso of the Chilian hunter, are formed by twisting together thongs of ox's hide; and in our own country at the present day ropes for particular purposes are made of horse's hair. The coir-ropes of Ceylon and the Maldive islands are made from the fibrous husk of the cocoa-nut; the Manilla rope from the fibres of a species of the wild banana, the *Musa textilis;* and the *Sunn* ropes from those of the *Crotolaria juncea.*

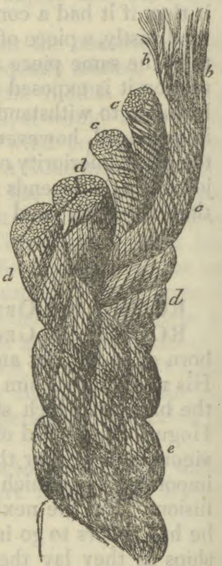
Many other vegetables have fibres of great tenacity, and fitted for the purposes of the rope-maker; but preference is given to those of the *Cannabis sativa,* or cultivated hemp, and the *Linum usitatissimum,* or flax, the fibres of both of which possess in a remarkable degree the essential qualities of flexibility and tenacity. Some idea of the importance of the manufacture under consideration may be obtained from the fact that, in the year ending January 1839, the value of the hemp alone imported into Great Britain and Ireland was L.617,597, and the value of the cordage exported was L.94,639.

The fibres of the hemp are first twisted together to form a thread or yarn. Many yarns are then combined by twisting, and form a strand; three strands are in like manner combined, and form what is properly a rope, and technically termed a shroud-laid rope or hawser-laid rope; and three of these ropes may be again combined, forming what is termed a cable-laid rope. The fibres should be so arranged that each in the finished rope shall offer the greatest resistance to its being torn asunder in the direction of its length.

If we take a bundle of fibres, equal in length and strength, and fasten it at the ends, each fibre will, upon a strain being applied to the bundle, bear its proper share of the stress; and the strength of the bundle will evidently be measured by adding together the strength of the separate fibres. But if we twist this bundle so as to form a thread, the strain will no longer be equally distributed among the fibres; for, by the torsion, the external fibres of the bundle will be wound round those that lie nearest to the centre, and, in proportion to their distance from the heart of the bundle, and the amount of twist given, will form spirals more or less inclined from the axis of the thread. The external fibres will in consequence be longer than the internal ones, and the greatest share of the strain will be borne by the latter. Further, by the operation of twisting, the fibres in a thread are strained, and, on account of their position, the external ones the most. It is of importance to consider the proper length of the primary fibres, and the degree of torsion that ought to be given in forming them into a thread.

All threads require the fibres to be so fine, and of such a length, that the quantity of fibres used, and the number of turns each has round its axis, shall be so great as to produce the necessary compression amongst them, to prevent them from sliding upon each other. If the thread be small, the fibres must be fine, and may be short; and if the thread be large, then must the fibres be long. If the fibres be long in proportion to the size of thread to be made from them, less twisting will obviously be necessary to keep them from sliding; and the finer and softer the fibres are, the more may the twist be diminished; for soft fibres enter into closer combination with each other than those that are hard. Long fibres requiring thus less twist than short ones, it has been a standing rule with all theoretical writers, that fibres should always be spun into the thread endlong, and never by their bight or double. Now, in the practice of hand-spinning, the fibres are always spun into the thread by their bights, and never by their ends.

Fig. 1.



It is certainly an advantage in threads which are to be used merely as such, to secure as great a length of fibre as possible, as any strain tends directly to pull the fibres asunder; and they are retained in their position merely by the compression among the co-fibres, produced by twisting. But many threads are combined in forming strands; new forces are brought into action, and so at every further combination. This will be better explained by the following diagram. Let *aa* be the primary fibres, formed into threads *b;* in each thread the fibres are retained in their position by the compression produced by twisting. Let *bb* be threads twisted together to form a strand. Here the threads mutually compress each other, and the primary fibres of each thread are compressed by the surrounding threads. Let *cc* be strands twisted to form a hawser-laid rope. In this the compression on the primary fibres is again increased, and so in the next combination, where the three hawser-laid ropes are twisted into the cable-rope *d.*

We may from this deduce, that it is not the length so much as the intrinsic strength of the fibre which fits it for the purpose of the rope-maker; and practice perfectly fixes this position, the ropes made from the short waste fibre of the hemp called tow being by no means so weak when compared with those made from the hemp itself, as theory would lead us to suppose, seeing that these fibres are the shortest and weakest of the material. It may therefore be laid down as a rule, that in the making of ropes it is of greater consequence that the fibres should be strong, soft, and finely hackled, than that they should be of great length.

Let us consider a little more how the twist of the thread is affected by its future combination. The fibres are first twisted in a certain direction to form threads. A collection of these threads is then twisted together to form a strand; and this last twist being in a direction contrary to that of the threads, untwists them to a certain extent.

Had the twist in the first instance been no more than would just have kept the fibres from sliding upon each other, it would now be inadequate to produce that effect. Hence one would think it necessary to provide means to put more twist into the threads as they were being formed into strands, or to put as much more twist into the threads while spinning, as the twisting of the strands abstracts from them; but when these strands are combined to form a hawser-laid rope, the direction of the twist is again the same as that of the threads, and restores to them a certain portion of what they had lost. If, however, three of these hawser-laid ropes are formed into a cable-laid rope, the threads are again to a certain extent untwisted. The untwisting suffered by the thread in forming the strands is much greater than the subsequent retwisting in forming the rope; and if the thread had been at the first too little twisted, or too soft, as it is termed, it would never make a serviceable rope; and for such ropes as require to be impervious to water, it would be totally unsuitable.

It is, then, on the proper angle of twist in the *combined* threads, and not in the threads when *separate*, that the efficiency of the rope depends; and this can be determined by experiment alone.

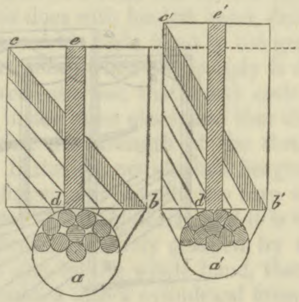
When many threads or yarns are combined to form strands, the effects produced on the latter by strains are analogous to those produced on the fibres when formed into threads, and, from the greater size of the component parts, are more apparent.

In the ordinary method of procedure the threads are all stretched to the same length, and then twisted together in a direction contrary to their individual twist. This, by winding the external yarns round those beneath them, shortens the whole mass, and puckers up the yarns nearest the centre, and thus the greatest share of any strain is thrown on the external yarns. It has therefore been considered of primary importance in all inventions intended to improve the making of ropes, to equalize the strain on the yarns in the strands.

Belfour attempted to effect this by shortening the internal yarns in the degree necessary to prevent their puckering up. Now, although the fibres of hemp are not in themselves very extensible, yet the rope formed from them is; and when such an extension takes place in a rope formed by Belfour's method, the strain is thrown entirely upon the internal yarns, which, if the strain be great enough, will break from the centre outwards.

The manner in which the external yarns of a strand lengthen, will be seen at once by fig. 2. Here *a* is a section of a newly formed strand; *a'* a section of the same strand after having been used; while *b'c'* is a part of the surface of the first, on the stretch out; and *b'c'* a part of the surface of the other. By the straining produced by use, the yarns in *a* are brought into closer contact, and the diameter of the strand is reduced. If in the strand *a*, *bc* represents the angle at which any external yarn is supposed to lie, this, by the reduction of the diameter, will in *a'* be changed to *b'c'*; and if in *a*, *de* represents a heart-yarn, this yarn in *a'* must stretch to *e'*, or break, which, as it is very little extensible, it is likely to do. It is of importance to observe, that the breaking of the heart-yarns of a strand in this manner is attended with much greater danger than the breaking of the external yarns, as the injury not only remains concealed, but water can easily penetrate to the core of the strand, which in consequence speedily decays.

Fig. 2.



It would appear, then, that a certain degree of puckering in the internal yarns of a strand is necessary to compensate for the extension that the superficial yarns undergo by use; and where ropes are made by machinery, it would be perfectly possible to arrange it so that, from the central yarn outwards, every one could be wrought into the strand in due length to allow for the stretching.

The further operations are the forming the strands into hawser-laid ropes, and these again into cable-laid ropes. The many uses to which ropes are applied preclude the possibility of applying specific rules to their manufacture. Some require flexibility, others impenetrability to water; strength may in some be of primary importance, or it may be secondary to other qualities which better adapt the rope for its peculiar purpose. The goodness of the rope depends upon the previous operations; but it must be a standing rule in all the processes, never to make use of so much twist as will impair the strength of the fibre.

To prevent the decay of such ropes as are exposed to continual changes from wet to dry, the yarns forming them are soaked in hot tar previously to their being worked up. It would be well if some other substance than tar could be found suited for this purpose, as it unfortunately happens that ropes lose much of their strength in the operation of tarring; and after having been kept for some time, the loss of strength is progressively increased, and this to a greater extent in hot than in cold climates. M. Duhamel made several experiments on this subject in 1741–1746, and from the results obtained he concludes,

1st, That untarred cordage in constant use is one third more durable than the same cordage when tarred;

2dly, That untarred cordage retains its strength for a longer time when kept in store;

3dly, That untarred cordage resists the ordinary influence of the weather one fourth longer than when it is tarred.

Some experiments were made in 1803 by Mr Chapman, civil engineer, to determine the effects of a new process of washing the tar to free it from the soluble substances contained in it, and for which process he had obtained a patent. Yet although the result of these experiments proved beyond a doubt the superiority of Mr Chapman's method, it is singular that it has never come into use. The same gentleman made some other experiments in 1806–1807, confirmatory of those of M. Duhamel. The result of one series is given in the table below.

Date of Experiment.		Girth in Inches.	Breaking Weight.	Comparative Strength.	Cwts. on each Inch of Square of Girth.
1806, Oct 2.	White rope.	2·75	75 cwt.	100	9·9 cwt.
—— Oct. 24.	Tarred rope.	2·8	55	73·3	7
1807, May 8.	Same rope...	2·8	41·4	55·2	5·3

We shall now offer a few of the rules which have been given by different authors for computing the strength of ropes.

Mr Tredgold says, "that in a hawser-rope, it may be proved that the strength of the straight fibres of hemp is to the strength of the rope as the radius is to the mean between the square and the cube of the cosine of the angle of twist, when the fibres are all equally extended, and the angle of twist measured at the greatest stretch the rope will endure without fracture. The cosine of the angle under these circumstances is in general about 0·87, and therefore the strength is about 0·708 times the strength of the hemp, or very little exceeding two thirds of its strength; but in most cases the loss of strength will be greater than one third, because the stretching of the different parts is unequal. And in a cable-laid rope, that the strength of the hemp is to that of the cable as the radius is to the mean of the third or fourth power of the cosine of the angle of twist under the same circumstances as before; or, that its strength is to that of the ropes which form it simply as the cosine of the angle of twist. This, in usual cases, will be nearly as eighty-seven to a hundred, that is, there are thirteen parts in every hundred of the strength lost in forming cable-laid ropes."

The following rule is given by Dr Robison for finding the strength of ropes: Multiply the circumference of the rope in inches by itself, and the fifth part of the product will be the number of tons which the rope will carry. Thus, in the experiment of Mr Chapman, the weakest tarred rope

Rope-making.

broke with two tons, and by our rule we find that it ought to carry with safety one ton eleven hundredweight.

The following rule may also be of use. To find the weight in pounds of a foot in length of any hempen rope, multiply the square of the circumference in inches by 0·045 for shroud-laid ropes, and by 0·027 for cables. (B. S.)

Rope-making is the art of combining fibrous materials, by twisting in such a manner as to form a continuous flexible cord.

We have before stated, that the fibres used for this purpose are those of flax and hemp; the former for small lines and cords only, and the latter for all kinds of cords, from the smallest to the largest. The preparation and manufacture of hemp and flax into such articles as either are adapted for, being the same in both, we mean, in the following sketch of these operations, to speak of hemp as the material made use of. This article we obtain from Riga and St Petersburg, whence it is shipped for our ports in great bundles, weighing, according to quality, from forty-five to sixty-five poods each, the pood being equal to thirty-six pounds avoirdupois. On the arrival of the vessels, these great bundles are cut up, and the hemp is thrown from the hold in small bundles, bound at one end, and weighing each about twelve pounds. These small bundles are termed heads; and in this condition the rope-manufacturer gets his raw material.

The fibres of hemp, of a good quality, should be long, fine, and thin; smooth and glossy on the surface; of a yellowish-green colour; and free from spills or small pieces of the boon or woody fibre of the hemp plant, which remain after the operation of breaking; and they should, above all, possess the essential qualities of strength and toughness.

Hemp loses many of its good qualities by lying long in warehouses; and when shipped in a damp state it loses its glossy appearance, becomes what is termed rusted, and is then much weaker, and hard and disagreeable to work.

The operations of the rope-maker are carried on in the following order, viz.

1st, Hackling the hemp.

2dly, Spinning or twisting the fibres into threads or yarns.

3dly, Tarring the yarns.

4thly, Making the yarn into strands.

5thly, Laying or forming the strands into ropes, called hawser-laid ropes.

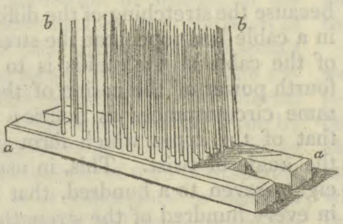
6thly, Laying or forming hawser-laid ropes into cable-laid ropes.

1st, Hackling.—To prepare the fibres for the use of the spinner, they are drawn over pronged instruments called hackles, which clear from them the refuse, and split them into different degrees of fineness, to suit the size of thread into which they are to be spun.

Fig. 1 is a representation of a hackle of the largest kind, called a cag. Here *aa* is a strong board; and *bb* steel prongs, polished and tapered, and made very sharp at the point.

The prongs of the next size of hackle are smaller and closer set, and so on, diminishing to the finest size, which reduces the fibres to the last degree of tenuity.

Fig. 1.



The operation of hackling is performed in the following manner. The operator stands at a convenient distance in front of the hackles, which are fixed on a steady bench at a proper height. He then takes a bundle of hemp, and divides it into such portions as he can conveniently grasp. One of these he holds firmly by one end, and draws it over the hackle, beginning with the end of the bunch farthest from his hand, and by repeated operations disentangles and splits the fibres nearly to where he grasps the bunch. He then takes hold of the finished end, and operates on the part which he before had grasped. To facilitate these operations, he from time to time oils the hemp with a little whale-oil. When the hemp is combed out and split as perfectly as the first size of hackle enables the workman to do, he carries it, if it be necessary for the purpose intended, to the next in degree, and so on to the last. The short fibres which are pulled out of the bunch by the hackle, and remain sticking to it, are collected from time to time by the workman, as they impede his progress, and are laid aside. They are afterwards drawn over the hackle to lay the fibres straight, and are, under the name of tow, used in making inferior ropes.

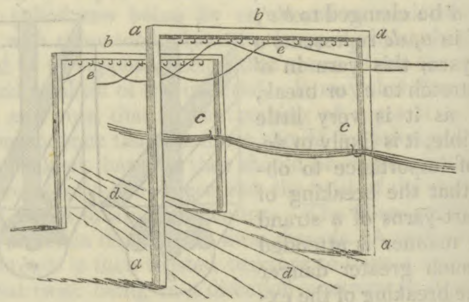
As the workman finishes his handfuls of hemp, he lays them aside in bundles for the spinner.

The operation of hackling would seem to require little skill on the part of the workman; but this is by no means the case, as bad workmanship would convert the greater part of the hemp into tow. Hackling is performed in a house, which ought, for convenience, to be near to where the threads are spun, that the spinners be not put to unnecessary expense of time in getting their stuff.

2dly, Spinning.—The place where the operation of spinning is carried on, is one division of a walk or alley termed the rope-walk, and is generally enclosed by walls, and roofed over; and in some places where ropes and twine are made, the building is in two stories, the rope-yarns being spun below, and the twine in the loft above.

The walk for rope-yarns is, according to circumstances, from 600 to 1200 feet long, and the width is regulated by the extent of the business to be carried on. One end of the walk is termed the head or fore-end, and the other the foot or back-end; at both ends the machines for communicating twist to the yarns are erected; and along both sides of the walk, at equal distances, and opposite to each other, are erected posts. Between every pair of posts a rail stretches across the walk, at the height of eight feet above the ground; and along the under side of the rail, hooks are fixed, on which the yarns are hung as they are spun; and to one of the upright posts of each pair a large hook is fastened, on which the yarns are hung when collected together. Fig. 2 shows this arrangement; *aaaa* being the upright posts, *bb* the rails stretching across the spinning walk, *ee* the hooks for the yarns, and *cc* the large hooks on which the collected mass of yarns is hung. At the head of the walk a stout post is fixed in the ground, and to it the yarns are fastened as they are finished. At the foot of the walk a similar post is fixed for the same purpose. These posts must be at that side of the walk on which the large hooks are fixed.

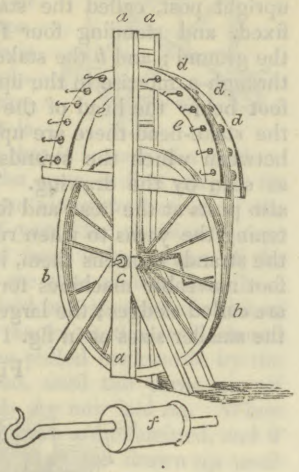
Fig. 2.



The walks on which small threads for twines and small cords are spun, have, in place of these rails and hooks, rails about three feet long, let loosely into mortises sunk in the top of upright posts, about three and a half feet above the ground; and along the top of the rail upright pins are fixed, to keep the threads separate.

The spinning machines for rope-yarns consist of two upright posts, *aaa*, fig. 3, between which the wheel *bb* is hung on its axis *c*. A belt from this wheel passes over and gives motion to a number of small pulleys, called whirls, *ddd*, inserted in a circular arc *ee*, called the head, fixed to the top of the posts. The axis of each of these pulleys is prolonged in front of the head, and bent into a hook, as shown more distinctly at *f*; and on this hook the fibres of hemp are hung to be twisted.

Fig. 3.



The spinning-wheel for the smaller sorts of threads differs from this chiefly in being smaller, and having the parts slightly modified to suit the diminution of size.

The operation of spinning is conducted as follows. The spinner takes a bundle of hemp of sufficient size to make one or more threads the whole length of the walk; he puts this bundle round his waist, the bight or double being in front, and the ends passing each other at his back; and he secures it in this position by buckling a strap round it, or by fastening it with his apron. He then draws out from the face of his bundle as many fibres as he thinks will make the size of yarn required; the bight of these fibres he hangs on one of the whirl-hooks, and the wheel being now turned by an assistant, it throws twist or turn into the fibres. The spinner having laid a piece of thick woollen cloth in the hollow of his right hand, with the end hanging over his fore-finger, grasps with it the fibres he had drawn out, pressing them firmly with his thumb and forefinger, the interposed cloth preserving his fingers from being cut by the fibres as they pass. He now walks backward down the walk, that is, from the head to the foot, the wheel-man all the while turning the wheel just so fast as to keep the turn or twist up to the spinner, of which he is admonished by signs made by the left hand of the latter, or, in complete establishments, by a bell, the cord of which traverses the walk. The aim of the spinner is to regulate the supply of fibres from his bundle in such a manner as to render the thread equal in size throughout. This he does with his left hand, drawing back the fibres as they enter his right hand in too great number, and pulling forward more when the supply is deficient in quantity. He takes care, too, that many ends of fibres do not come together in the same place, and that they so arrange themselves as that the strength of the thread shall be equal throughout. If the spinner slacken his grasp of the fibres with his fore-finger and thumb, the turn will pass his hand, and the thread will be spoiled; and it is necessary not only that the thread be firmly grasped by the thumb and fore-finger, but also by the whole hand, that it may be compressed and moulded into a cylindrical form.

We have hitherto described the operation as performed by one spinner; but as many spinners may work together as there are whirls in the head. Suppose, then, that all the spinners have set on, as the fastening of their threads to the whirls is termed. They proceed together down the walk, and when they are a few paces below the first rail, *b*, fig. 2, every man throws his thread on one of the hooks, and so at each rail, until they arrive at the foot. They then join the ends of every pair of yarns, and hang them over the post already mentioned; and for the convenience of afterwards separating them, the pairs are kept apart in the following manner. A piece of twine is tied by its middle to the first pair, a little in advance of the post; the second pair is then put over the post, and the string is tied over them; and in like manner every pair is tied in. This is called nettling. The spinners now set on at the foot or back-end wheel, and spin up the walk. The fore-end wheel-man having unhooked the yarns from the whirls of his wheel, and hung them over the post, and tied them in pairs as at the back-end, proceeds down the walk, collecting the yarns from the hooks of the rails, and laying them in a heap in the large hooks *c*, *c*, fig. 2. When the spinners again spin down the walk, these same operations are performed by the back-end wheel-man. When the collected yarns number about 400, they are coiled up in a haul, and are ready either for tarring, or laying into white ropes. Previous to the haul being taken up for tarring, there is a slight turn put into it to keep it from getting entangled in the tar-kettle. In the government rope-works, by the regulations of 1802, the spinners had to produce, from a bundle of hemp weighing 64 lbs., 18 threads of 170 fathoms each; 400 of such threads constituted a haul, and weighed 12 cwt. 2 qrs, and when tarred 15 cwt.

3*dly*, *Tarring*.—The next operation is that of tarring. This is variously performed. Here we shall describe the simplest method of doing it.

The apparatus used in tarring consists of a copper bedded in brickwork with a proper furnace below, and flues around it. The copper is termed the tar-kettle, and at one side of it is erected a strong frame, in which a capstan works.

Fig. 4 shows this arrangement. Here *a* is the kettle; *bb* the frame; *cc* the capstan, which may be turned either by manual labour, or horse or other power; *dd* a truck, on which the haul is being coiled away as it comes from the capstan; and *ee* small rollers by which the haul is supported. In the upright nearest the boiler is fixed the nipper for squeezing the superfluous tar out of the haul. The nipper is drawn to a larger size in fig. 5. Here *aa* is a copper-plate with a hole in it about two and a half inches diameter; above it another plate *bb* slides, and out of its lower edge a semicircular piece is cut, corresponding to the hole in the lower plate, so that by sliding this plate down, the aperture is diminished. A lever *dd* of the second order is fixed at one end to the chain *c*, and presses on a stud fixed on the upper plate, so that by moving the weight on the lever the yarn may be pressed to the degree necessary as it passes through the aperture; and as the tar oozes out of the yarn, it is received and carried back to the kettle by the spout *f*, fig. 4.

Fig. 4.

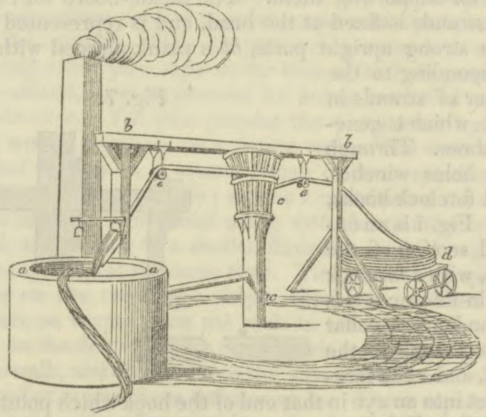


Fig. 5.

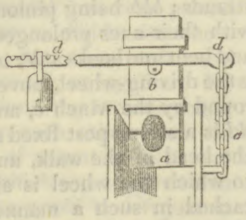
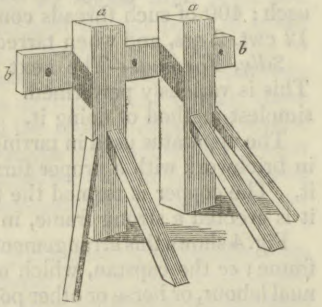


The tar having been put into the kettle and heated to the proper degree, which is about the temperature of boiling water, and is known to the workman, in the absence of more correct means, by a scum closing over its surface, the

Rope-making.

superintendent begins to pass through the haul. A rope attached to the capstan is passed through the nippers, and attached to the end of the haul. The haul is then coiled gradually into the kettle, and the capstan is moved round. The haul is thus drawn slowly through the tar, and the superfluous tar squeezed out of it as it passes through the nippers, the superintendent regulating the weight on the lever, so as to produce the required pressure; and the end of the haul, as it comes from the capstan, is coiled away, or reeled upon large reels. In this operation the heat of the tar is the most important point to be attended to. If it be too hot, the yarn will be charred; and if too cold, it will be black, whereas yarn intended to be made into ropes should be of a bright-brown colour. The proper heat is indicated, as was before stated, by a scum closing over the surface of the tar, which takes place at about 212° Fahrenheit. If this scum do not rise, the tar is too cold; and if there be an appearance of ebullition, the tar is too hot.

Fig. 6.



4*thly, Forming Strands.*—The yarn is now ready for the next operation, which is the making of the strands. This comes under the head of laying. The place where this and the subsequent operations are carried on is termed the laying-walk; it is generally part of the alley of which the spinning-walk forms a portion, and it may be of such a width as to allow of many ropes being made at one time. The fixtures of this walk consist of tackle-boards and wheels for twisting strands, and stakes and stake-heads for supporting them. The tackle-board for twisting large strands is fixed at the head, and is represented in fig. 6; *aa* strong upright posts, *bb* a plank pierced with holes corresponding to the number of strands in a rope, which is generally three. Through these holes winches, called forelock hooks, work. Fig. 7 is an enlarged section of the board, with a forelock hook in its place; *a* is the handle, *b* a collar working against the board, and *c* the forelock let into an eye in that end of the hook which points down the walk. Fig. 8 is a representation of one of the wheels for twisting smaller strands; *bbb* being pinions with their axes prolonged, and bent into hooks at *b'*; *aa* is the driving-wheel, moved round by the winch *c*, and *dd* is a strong post fixed at the head of the walk, and to which the wheel is attached in such a manner that it can be easily disengaged, and a larger or smaller wheel applied, as the rope may require. Corresponding to every twisting apparatus, at the head there is a row of bearers or stake-heads for supporting the strands when twisting, and extending from the top to the bottom of the walk. These are represented in fig. 9, where *aa* is an upright post, called the stake, firmly fixed, and standing four feet above the ground; and *b* the stake-head, let through a mortise in the upright at a foot below the head of the post. In the stake-head there are upright pins, between which the strands are laid, as seen by the drawing. There are also posts at the head and foot for fastening the yarns to when run out for laying. As twisting the strands shortens them, it is necessary to provide at the foot moveable machines for communicating twist. These are called sledges; the largest are formed as in fig. 10, and the smaller sizes as in fig. 11.

Fig. 7.

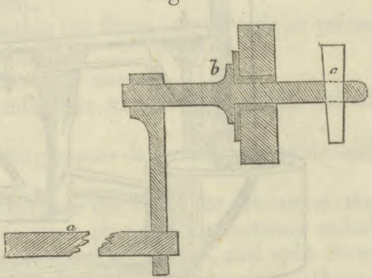


Fig. 8.

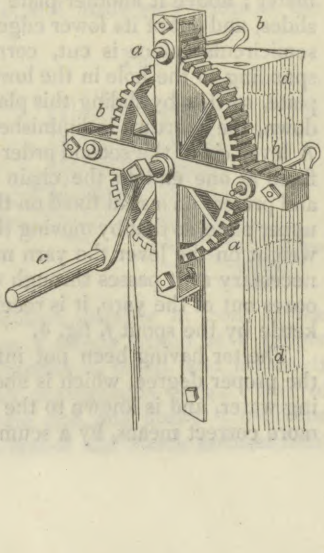

Fig. 9.

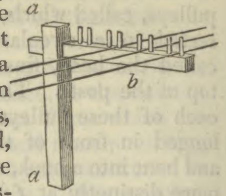

Fig. 10.

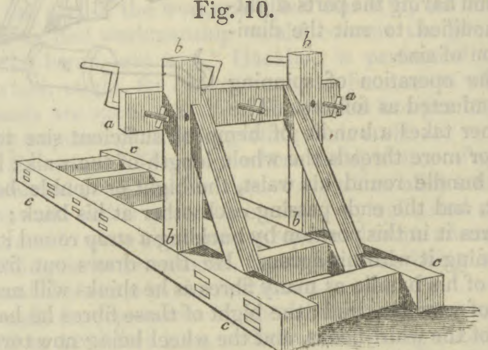
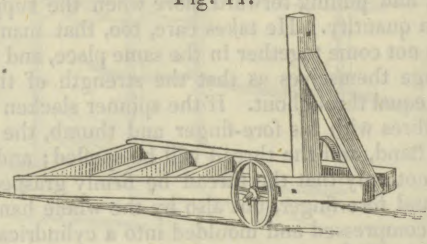


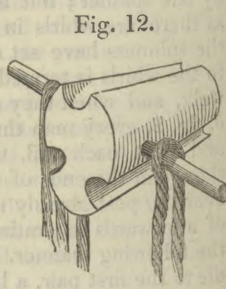
In fig. 10, *aa* corresponds to the tackle-board, and is called a breast-board; it is bolted to the uprights *bb*, which again are firmly fixed and stayed to the frame *cccc*. The part of the frame behind the uprights is called the tail of the sledge, and on it are laid weights to afford pressure enough to keep the strands stretched. These weights consist of old tar-barrels filled with clay, and are called press-barrels. In laying large ropes, sufficient pressure cannot be obtained by the barrels; and in that case a double block and tackle is used, one end being fastened to a strong bolt behind the sledge, and the other to the tail of the sledge, and with the tackle-fall a turn or two is taken round a post. The smaller sledges (fig. 11) have only one upright post, to which some one of the wheels, similar to fig. 8, is fixed; and they have likewise two trucks to run on.

Fig. 11.



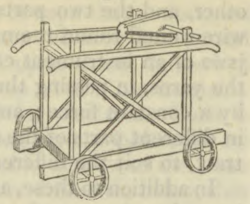
Of the smaller implements used, the first are the tops (fig. 12) for laying the strands into a rope. These consist of conical blocks of wood, of different sizes, having three equidistant grooves along their surface, and pins through them laterally, serving for handles. A piece of soft rope is attached to each handle of the top by its bight, and the ends are used to wrap round the rope in the process of laying. These ropes are called tails. When the top is very large, it requires to be supported on a sledge, as shown in fig. 13; and in that

Fig. 12.



case the tails are attached to the sledge. Woolders are stout pins with a rope fastened to one end, and are used to assist the action of the machine in twisting the rope. In addition to the above, there is used in making white ropes a rubber, formed of steel rings interwoven like linked mail; and it is probably from the resemblance that it is termed a mail.

Fig. 13.



In the operation of laying, the yarn is first warped for the strands. The haul is run out along the bearers of the laying walk, and the number of yarns for the size of rope about to be made is separated from it by means of the nettling. The separated yarns are then divided into three equal portions. Each portion is laid in a separate division of the bearers, and hung upon its hooks at the tackle-board and sledge. The sledge is then pulled backwards by the tackle-purchase before described, until the yarns are all stretched tight, and press-barrels are now laid on. When things are in this position the threads are examined, and if any be longer than the others, they are drawn up until every yarn is equally tight. The hooks at each end are now heaved round *in time*, and in a direction contrary to the spinning twist; and each collection of yarns is twisted round its axis, and becomes a strand. The twisting of the strands shortens them, and draws the sledge up the walk.

When the torsion in all the strands is sufficient, or when, in technical language, the strands are full hard, the twisting is stopped. The sledge is then drawn up the walk a small piece to slacken the strands and allow the outer ones to be taken off their hooks and hung on the middle hook. It is again drawn back by the purchase, and the top (fig. 12) is inserted among the strands which will occupy its grooves.

The top is now forced back as near the hook of the sledge as possible, and the workmen at the head again turn their hooks in the same direction as before. As soon as the workmen at the sledge perceive it moving forward, they remove some of the pressure, and begin to turn their hook in a direction contrary to its former motion. The top is by this forced forward, and the three strands closing behind it form the rope. When the top gets far enough from the sledge to admit of their application, the tails are wrapped round the rope, and by their friction they enable the workmen to keep the top from moving forward by jerks, and they also make the rope close better. The care of the topman is to regulate the speed of his top in relation to the twist at both ends, the mean of doing which is simple. He makes a mark across the strands at every bearer previous to putting in the top. If, when the top reaches a bearer, he find the mark above the bearer, then the turning at the fore-end is too fast for the motion of the top; and if below the bearer, then the turning is too slow.

In the case of a very thick rope, the power of the men applied to the hook of the sledge is insufficient of itself to pass the turn up the rope. To aid them, other workmen apply the woolders at necessary intervals between the sledge and the top. The strap of the woolder is wrapped round the rope, and the pin used as a lever to heave round the twist; the workmen at the woolders keeping time in their heaving with those at the hook of the sledge. And in the case of a heavy rope, the top sledge (fig. 13) is made use of to support the top.

The mail is used for white ropes only. When the strands are hardened, and before the top is put in, workmen rub the strands with the mail to smooth down any rough fibres, and give a good surface to the rope.

We have now seen that in the processes described, every step is dependent on the skill of the workmen. In supplying fibres of hemp in due quantity to form the thread, in giving the proper degree of twist to the thread, in giving the strand the degree of hardness required, and in the proper speed of the laying top, the workman has no certain guide; and it is surprising that, although machinery for the improvement of almost every other manufacture had been introduced, no attempt appears to have been made to apply it to the art under consideration, until about 1783, when a machine to supersede the necessity of a rope-ground was invented by a Mr Sylvester; and this invention was followed up by many others. Such of these as have come under our notice are briefly described in the following account of them, arranged according to their dates.

1783. About this time Mr Sylvester's machinery was invented. In it the threads were spun by bobbins and spindles; the three several quantities required for the strands were wound on three separate reels, which turned individually round their axes, and also round a common centre, by which motions the rope was formed; and by the machinery it was further wound up as it was made. This invention was not patented, and was never carried into effect.

1784. In this year a patent was taken out by a Mr Seymour for improvements in rope-making; but the invention consisted in the substitution of animal for human power to drive the ordinary machinery of the rope-work.

1792. In this year the Rev. Edward Cartwright took out a patent for a rope-machine, which he called a cordelier. A part of this machine was adopted by Mr Huddart in a patent taken out by him in 1805.

In the machines of Sylvester and Cartwright the only advantage proposed was the saving of labour. There was no attempt made to improve upon the old defective principles of rope-making; the merit of the first attempt to do this is due to the next inventor.

1793, March 16. John Daniel Belfour, of Elsineur, obtained a patent for machinery "to improve the manufacture of ropes and cordage, by making every yarn employed in the composition thereof bear its proper and equal proportion of the stress." This the patentee proposed to effect by keeping every yarn tight at the time of its being twisted into the strand, so as to prevent its being puckered up in the inside of it. For this purpose the yarns were by machinery wound regularly on separate reels. The reels were suspended in tiers in a square frame on iron spindles on which they could turn freely; and by a contrivance the reels could be made to turn round along with the spindles when required, and motion in a similar direction could be given to all the spindles at the same time. The yarns were spread regularly on the reels by a simple apparatus. When the yarns were so wound upon the reels in the frame, the ends of those on the first or lowest tier of reels were carried down the rope-walk, and dropped into the separators, one of which was placed at every fifteen fathoms or so. These separators consisted of a series of vertical bars, fixed to a frame at their lower end, the upper ends being left free; into the intervals between these bars the yarns were dropped, and the different tiers kept separate by horizontal iron rods passed through holes in the side bars, so as to divide the whole frame into a series of reticulations; and these rods were so contrived as to be withdrawn separately or together. By being passed through these reticulations, the threads would be suspended at equal distances from each other from the top to the bottom of the walk, and, if meant to form one strand, would be hung on the hook which was to give them motion; and on the reels in the frame would be left just so much yarn as the strand should take up in hardening. The strand would then be ready for twisting; and to do this in such a manner as to make every yarn occupy its proper place, Mr Belfour employed an instrument called a top-minor. This was a block of wood formed somewhat like a sugar-loaf, and having inserted round its larger circumference a number of projecting pins. Into the recesses formed by these pins the yarns were inserted, and motion being given to the wheel, the top was moved slowly up the walk by the workman, the reels at the same time giving out the yarns as they were taken up by the twisting. When the workman arrived at the first separator, the iron rods were, by the contrivance already alluded to, at once withdrawn, and the yarns left free, and so the workman proceeded until he arrived at the reel-frame, when the turning or heaving at the hook was stopped, and the strand prevented from untwisting, by being seized in a kind of nipper formed of iron. The ends of the yarns were then unfastened from the reels, and the strand was completed. By increasing the size of the reel-frames and separators, and by using three top-minors fixed to a sledge or otherwise, three strands could at the same time have been formed. The strands formed by this machinery were then laid together into ropes in the ordinary manner.

1793. In April 12th of this year, Mr Richard Fothergill obtained a patent for rope-machinery, embracing the following objects: First, freeing the hemp from its native husk, and fitting it for the subsequent processes; secondly, dressing the hemp, and drawing it out into slivers fit for spinning; thirdly, spinning the hemp; and, fourthly, twisting or making it into ropes or cordage. All these operations required no rope-walk to carry them on. Engravings of the machinery will be found in the fourteenth volume of the second series of the Repertory of Arts.

1793. In April 25th, Mr Joseph Huddart took out a patent for certain improvements in the formation of ropes. His method of registering the strands, in order to acquire an additional degree of strength, by giving the length of the yarns which compose the strand a certain ratio, according to the angle and hardness or compression the rope is intended to be laid with, and thereby acquiring a more equal distribution of the strain upon the yarns than ropes made in the common way, consisted of the following principles: First, by keeping the yarns separate from each other, and drawing them from bobbins which revolve, to keep up the twist whilst the strand is forming; secondly, by passing through a register which divides them by circular shells of holes, the number in each shell being agreeable to the distance from the centre of the strand, and the angle the yarns make with a line parallel to it, and gives them a proper position to enter; thirdly, by a cylindrical tube, which compresses the strand, and maintains a cylindrical figure to its surface; fourthly, by a gauge to determine the angle which the yarns in the outside shell make with a line parallel to the centre of the strand when registering, and according to the angle made by the yarns in this shell, the length of all the yarns in the strand will be determined; lastly, by hardening up the strand, and thereby increasing the angle in the outside shell, which compensates for the stretching of the yarns and compression of the strand.

In this, as in Belfour's invention, the registering apparatus was moved up the rope-walk by the twisting of the strand; but the machine differs from Belfour's in the following particulars. First, in place of the bobbins or reels being fixed in an upright frame, they are placed in horizontal ranges, each range rising higher from the front towards the back part of the machine. Secondly, in place of the separator of Belfour, sets of horizontal rails, notched to receive the yarns, and hung in cleats fixed to upright posts, are placed at regular intervals down the walk, so as to keep the yarns separate the whole length of the strand. Thirdly, in place of Mr Belfour's *top-minor*, a plate pierced with concentric circles of holes is made use of, the circles being about two inches asunder; and behind this plate a smaller plate, pierced with a similar number of holes, is fixed, the holes in the latter plate being so close together as merely to keep the yarns clear of each other. Immediately behind this last plate is fixed a tube made of thin steel, of a spring temper, and in two parts longitudinally; the thin edges of the one part overlapping those of the other, and the two parts being compressed by a thong or wire wound round them several times, and fastened to the jaws of an instrument called a heaver. By means of this, the yarns, in passing through the tube, can be compressed by a constant force; and if the yarns be thicker or smaller in different parts of the strand, the tube will expand or contract, to suit the difference of size.

In addition to these, an instrument called a register-gauge is used to measure the angle of twist of the yarns in the strands, with the view to employ the same twist when the strands are formed into a rope. Some of the parts of the machinery above noticed, it will be seen, have been adopted by other inventors, and some of them are still in use.

1797, September 13. At this time Mr William Chapman of Newcastle obtained a first patent for laying, twisting, or making ropes or cordage, of any number of yarns or strands, or any number of threads tarred or untarred, from the size of a cable down to the smallest line formed of more than one thread. The machinery for this purpose was less complicated than those formerly mentioned, but was only capable of forming ropes on the common principle. In the month of January 1798 he obtained a patent for Scotland for further improvements in rope-machinery, and containing the substance of his former one and of another taken out for England on the 6th of March 1798. The inventions embrace the making of ropes either by stationary machines, or by moving machinery on a rope-walk. In the former, the operations of forming the yarns into strands, twisting the strands into a rope, and coiling away the rope, on reels or otherwise, go on at the same time. One of the arrangements of the machinery by which these different operations are carried into effect, is as follows. Three or more discs, according to the number of strands, are placed round a common centre, with their planes inclined to each other in such a manner that their produced axes would meet in a given point. These discs are by the inventor termed strand-tables, and each of them is fixed to a hollow shaft, capable of revolving round its axis; which shaft is called the strand-shaft or upper shaft. These shafts are on the sides of the discs which are inclined to each other. On the opposite sides of the discs yarn-reels are suspended on spindles, on which they can turn freely. The yarns from the reels are passed through the shafts, and by the turning of the discs or strand-tables they are twisted into strands. In a part of the shaft there is a transverse opening to admit of two blocks of hard wood or other matter being applied on each side to press the yarns, and retard their passage through the shafts, so that they may be twisted to the degree required. These blocks are called press-blocks or compressors, and are held together by springs or weights. Instead of blocks the patentee sometimes substitutes rollers moving round their axes, and holding the yarns by their friction. Besides these, the yarns pass through a perforated plate called a yarn-guide.

The strand-tables all move round in one direction, and the strands as they proceed from the shafts are concentrated into a point, over a fixed grooved block, corresponding to the top in the ordinary process. Behind this block the strands are received into a hollow axis, which turns round in a direction contrary to the twist of the strand-tables, and in which the strands are formed into a shroud-laid rope, by being twisted by the apparatus attached to the shaft. This consists of a pair of wheels or sheaves, moving easily on their axes, to admit the rope a free passage, and at the same time compel it to twist equally round with the shaft. These sheaves are grooved in such a manner as to prevent the rope from turning sideways, and are called twisting-sheaves. Instead of the sheaves moving freely on their axes, such a motion may be given to them as in every revolution of the rope-shaft, which makes one turn of the rope, the groove of the sheaves shall move such a space as is equivalent to the length of rope that is designed to be made by every turn. When the rope has passed through these sheaves, it is coiled upon a reel in such a manner as merely to require tying up; but if too unwieldy for reeling, it is coiled on a revolving platform. Such is an outline of the process of making shroud-laid ropes by Mr Chapman's machinery. For cable-laid ropes the same or similar machinery is used, the chief difference being, that in cable-laid ropes the twists are contrary, and the disparity of turns in the strands and rope not so great as in shroud-laid ropes; for which reasons, if the same machine be used, the means must be provided for making the shaft to assume contrary motions, and making them to move in different proportions.

"By the method previously described," says Mr Chapman, "for making a complete rope at one operation, I, during the act of making the strands, unite them into a rope by means of what I then call a rope-shaft, in which they are all concentred, and receive the twist which forms them into a rope; but I also occasionally omit the concentring of them, and the subsequent part of the operation, during the making of the strand or strands, and in place of twisting them into a rope, I only draw the strand forward as made, and coil it or them in any manner whatsoever, they in this instance having no rotative motion. The apparatus for drawing them forward is not fixed to the revolving shaft, containing the reel or reels and other necessary appendages, but may be permanent, and receive its motion in any proportion whatever to the revolutions or twists given to the strand by that shaft.

"The principles of making the strand in these two different ways are obviously portions of the process that would, as has been described, make the whole rope at one operation. And these two methods of making the strand, independently of making the complete rope, are reducible to the following principle: That in making a strand simply, one end need only to be twisted, and the other held from turning, but that both be permitted to pass forward, and progressively change place; and that the yarns be, if deemed necessary, so regulated as to come off these reels in such a manner as the part of the strand they come into may require.

"There is a third method of making a strand, compounded of the two preceding, which may be followed, viz. that of using two revolving shafts in place of one; the reels being placed on one of them, and the strand coiling upon the other. These two shafts ought to turn in contrary directions to each other."

The part of the invention in which a common rope-walk is made use of is thus described by the inventor: "At the head of the ropey, or in any other part, I fix upon pins so many reels as will contain all the yarns requisite for a strand, or the given number of strands determined to be made at one time, each reel containing one or more yarns; then in the instance of making three strands, I fix to three different hooks on the foreboard of a sledge, so many yarns, separately concentring to each other, as are requisite; the yarns being previously passed through the openings of these separate fixed tops or yarn-guides, one opposite to or correspondent with each hook. Before, or on the face, or on the face of each top, toward the sledge, there may or may not be fixed a cylinder, such as I have described, below the laying block at the head of the rope-shaft. The yarns are then to be prevented from passing too easily off their reel, either by a pressure on the reels themselves, or on the yarns in their passage to or upon their separate tops, or in any manner that will permit them to come off as wanted.

"The men are then to heave upon, or turn round, the hooks of the sledge in the usual way; and the only remaining difference consists in the sledge being drawn progressively backwards, as the strand is making, until the whole, or any determinate part, of the strand be made. The process of drawing back the sledge may be done in various ways; amongst others, by a rope to a capstan, moved either by a horse or men, according to the strength requisite." When the strands are thus twisted, the rope may be completed in the usual way. Such, then, is a brief outline of the general features of these important inventions of Mr Chapman; but his own specification, with illustrative drawings, will be found in the ninth volume of the first series of the Repertory of Arts.

1798. In this year also Mr Belfour obtained a patent for an improvement on his former machinery; and in 1799 Mr Belfour's machinery was adopted in the government-yards, and the sum of L.4000 was paid to the inventor for his superintendence of the erection of his machine, and the use of his patent.

1798. November 8th, Mr Chapman at this time patented an invention, which was so to regulate the motion of the sledge that for every revolution of the strand it should move backward through the exact length of axis assigned to it, and thus render the twist uniform. The sledge, in this case, travelled backwards on a railroad; and along the whole length of the walk, a rope, called a ground-rope, was laid. This rope was passed in the form of an S round two or more grooved wheels, which were pressed together so as to bind the rope, and having upon their axles toothed wheels connecting them with each other, and with the hooks for twisting the strands, which in this case were driven by one great crank. Thus, when the hooks were driven by the crank to twist the strands, the sledge was also moved backwards by the grooved wheels acting upon the rope; and by changing the connecting toothed wheels the backward motion could be given in any ratio to the twist of the hooks. Besides this, Mr Chapman connected the sledge by a rope to a horse capstan at the foot of the walk; and as the horse's power applied to the capstan could not draw the sledge faster backwards than the ground-rope permitted, the spare power was of course given in aid of the twisting of the strands by means of the wheels which connect that operation with the backward motion.

1798. November 17th, Mr John Curr of Sheffield took a patent for forming flat ropes for the use of mines, &c. "The said flat rope may be formed," says Mr Curr, "by connecting two or more small ropes sideways together, by sewing or stitching, lapping, or interlacing them with thread, or small rope made of hemp, flax, or other fit material, or with brass or iron wire, in such a manner as to prevent their separating from each other, and so as to cause them to exhibit, as nearly as possible, a flat form, or flat pliable rope.

1799. April 30th, Mr Belfour obtained another patent for a further improvement on his invention. This consisted, among other things, in winding a number of yarns, not exceeding four, upon each reel, and forming them, as before, into strands. He farther proposed to spin the hemp after having been tarred; and also to place a spinning-wheel at each end of the rope-walk, to enable the spinners to spin both up and down in the manner now practised. If we mistake not, this method of spinning up and down is mentioned by Duhamel as being in use in his time. However this be, it was, on Mr Belfour's recommendation, adopted in the government rope-works, and, according to the report of Mr Fenwick, the master rope-maker at Chatham, a saving was effected by it to the amount of a sixth part of a day's work to each man.

1799. July 26th, Mr William Chapman, in conjunction with Mr Edward Chapman, took a patent for many improvements in the art; the first of which was for machinery to spin the yarns in such a manner that the fibres of hemp, on entering the thread, were shortened in proportion to their proximity to the axis; and further, that by this machinery, women, children, and invalids could be employed as spinners.

Although the yarn thus produced was of superior strength to hand-spun yarn, yet, as it was attended with additional cost in the manufacture, the invention was laid aside.

The next part of the invention was in the application of locomotive power to the machinery of the rope-work. Part of this consisted in the application of an endless rope, reaching from end to end of the rope-walk, and moved with considerable speed, to any of the machines, whether stationary like the fore-end wheels, or changing position like the sledges. The application of the endless rope to the sledge was effected by passing a turn round suitable grooved wheels fixed to the sledge, and capable of giving motion to its machinery. By this machinery great advantages were gained, as each revolution of the strands and the rope, and the proper motion of the sledge, were predetermined and fixed by changes of wheels. For this purpose tables were made out to show what wheels were to be used for each kind of rope. Instead of two hundred men, the number usually employed in closing a twenty-one inch cable, fourteen only were required; and they, with the help of the steam-engine, which was only of eight horse power, were able to coil away the rope when made.

1799. In the same month Mr Mitchell obtained a patent for a "method of manufacturing cables, hawsers, or shroud-laid ropes, and other cordage, on scientific principles."

These principles consisted in combining by twisting the integral yarns of a strand, in numbers of two, three, or more, previous to their being formed into the strand, and thereby lessening the strain on the external yarns when ultimately formed into a rope. The strain on the external yarns would doubtless be by this method lessened, but the number of yarns exposed to external injury would, at the same time, be increased. The ropes formed on this principle were by the patentee termed selvagee cordage.

1799. August 20th, Mr Huddart took out a patent for an improvement on his apparatus of 1793. In this the registering apparatus, instead of being moved up the walk, was, like Mr Chapman's press-blocks, fixed to the tackle-board, and the machinery for twisting the strands was stationary, and also contained apparatus for winding the strands upon reels as they were formed.

1799. In the same month Mr Grimshaw obtained a patent for improvements in rope-machinery, which consisted, first, in dressing the hemp preparatory to spinning; secondly, in winding up the yarn; thirdly, in preparing the yarns for tarring; and, fourthly, in laying the ropes or cordage. The first step appears to be best entitled to notice. The hemp in this was conducted to rotatory hackles through conical fluted rollers, by which means the hemp was equally mixed.

1800. July 1st, Mr Huddart took another patent for further improvements in the manufacture of cordage. "A considerable expense," says the patentee, "is attached to having the tarred yarns wound upon bobbins; and also the tar, especially when the ropes are laid in cold weather, is not sufficiently incorporated amongst the yarns to render it compact for durability, whether registered or laid in the common way. In order to obviate these inconveniences, I have invented a method of registering the strands of ropes during the operation of tarring the yarns, which may be effected in the following manner. The white yarns must be wound separately on reels or bobbins, and placed upon a frame or otherwise, so that the yarns may be delivered from them with as small and equal a tension as possible, and to pass under rollers, or through holes, or between separating rods of wood or metal, to be guided into the tar, when sufficiently heated in the kettle, and thence to the register, separate from each other, to prevent entanglement, until they enter the tube, which must be placed at the end of the tar-kettle opposite to that where the bobbins of white yarns are placed. The registering tube now acts in a double capacity, viz. in forming the strand fair, as in ordinary cases, and in acting as a nipper to squeeze out the superfluous tar. The strands are now twisted as before, and the twisting forces out some more tar, which must be cleared off by making the strand pass through the common adjustable nipper plate."

1801. July 16th, Mr William Hoard obtained a patent for "a portable machine for manufacturing ropes and cordage of any length in a short space, particularly adapted for shipping." This machine consists of separate reels, one containing the full length and number of yarns for a strand, from which reel they are drawn out to such distance as the two reels can conveniently be placed asunder, and are attached to the other, which is then empty, one of the reels being in a sledge or moveable frame. The process then begins by twisting the intermediate length of strand, until the reels have approached to each other the usual proportional space, namely, one fifth. The length of strand thus made is then wound up on the second described reel, and so much is let off from the first reel as to admit of their being at their greatest distance asunder, which process is necessarily continued until the whole strand be made, and wound up on the second reel. Lastly, three strands thus made have their ends united to a fourth reel placed opposite to them at its greatest convenient distance. By these four reels, the process of making the rope is carried on similarly to that of making a strand, except in the use of a top to regulate the progress of the twist of the rope in its approach to the three strand reels.

In 1801, Mr Archibald Thompson of Plough Court, Lombard Street, took out a patent for "certain new or improved machinery, for the purpose of spinning rope yarn and sailcloth yarn, and for laying and making ropes and cordage." Mr Thompson's invention includes the whole process of spinning, tarring, and laying the cordage. Preparatory to spinning, he draws out the hemp into a long sliver, by different sets of chain hackles, moving with progressively greater speed; and in the end the sliver is spun by a spindle with its plyer and bobbin into a thread. The threads remain wound up on their bobbins until wanted to be made into a rope, tarred or untarred. The bobbins are then, according to the number of yarns wanted in a strand, placed so as to form two circles of the same diameter, round an open cylinder consisting of three hoops or rings, distant from each other the length of a bobbin, and placed near to one end of a long horizontal axis; and, if the rope be to be tarred, the yarns are led through a ring of a few inches diameter, near that end of the described open cylinder which has the spare length of axis projecting from it. The yarns are then diverged in different degrees, so as to form, when passed longitudinally through an open cylindrical frame of several feet in length, so many different concentric circles round the axis mentioned, as there are different shells or concentric coats of yarns in the strand; and from the further extremity of this last-mentioned cylindrical frame, the yarns are concentrated to one focus at the extremity of the axis, which is there concave, and has an opening through which the yarns pass to the machine which is to twist them into a strand, and draw them forward to be coiled up within itself. At the focal point described, there are nippers to express the tar from the yarns, which is put into them in the following manner, viz. the last-mentioned open cylinder, between the ring from which the yarns enter to it, and the perforation of the axis where they concentre and quit it, lies over a tar-kettle, and has a portion of its lower half immersed in the tar, just so far as to imbue either the whole or any portion of the yarns with tar, as may be deemed expedient. This cylinder must, of course, turn round with such a convenient degree of speed as not to let the yarns be drawn off the cylinder before it comes in their rotation to pass through the tar. When the full length of strand is made, the twist of which is principally given by the revolution of the frame, in which it is progressively wound up during the process of making, the yarns are cut off; and three of these strands, from so many stationary strand frames, each of which has performed the operation last described, revolving only round its own separate axis, are concentred together, and pass through the axis of one end of a rotatory frame, which twists them into a rope, and coils it up, progressively as made, upon a barrel within the frame.

1801. Mr Cutting of the United States invented a method of making lines and ropes. His machinery was of much the same kind as Sylvester's, Fothergill's, and others already described.

1802. January, a patent was granted to Mr Chapman for his invention of the application of certain substances to the preservation of cordage. This has already been noticed under the head Rope.

1802. March 9th, a patent was obtained by Messrs Mitchell and Son for further improvements in rope-making, in addition to their patent of 1799. The specification of this patent will be found in the second series of the Repertory of Arts (vol. viii. p. 241).

1804. Mr Huddart took out a patent for a machine for manufacturing hemp and flax into yarn. We have seen that in hand-spinning the fibres of hemp are spun into the yarn by their bight or double, but by this invention they were to be spun into the yarn by their end. The spinner, in this case, instead of walking backwards, remained stationary, with the machine containing the apparatus for twisting at a little distance from him. In front of the spinner a table or other support, containing a number of upright pins like those of the hackle, was fixed. This table was made broad enough to hold on it half the length of the article to be spun, while the other end was held by the spinner. The spinner commenced his work by drawing some fibres of the hemp, and making them fast to the hook of a whirl; the machine was then set in motion, and the spinner with his spinning cloth took hold of and compressed the yarn as it was formed. By this means, says Mr Huddart, in his description, the longest hemp or flax may be spun without having its fibres reduced in length; for the pins before mentioned occasion all the fibres to be drawn out to their full respective length, or nearly so, and also prevent irregular drawing of the fibres.

It may not be amiss to mention in this place, that in France a method of spinning fibres by the end instead of the bight had long existed. Instead of the spinner fastening his bundle of hemp round his waist, it was fastened to a distaff by being laid along it and tied at the upper end, and the distaff was fastened by its lower end to the waist, and lay on the left shoulder of the spinner; the lower end of the bundle of hemp thus hung loose, and the fibres were spun into the thread endlong.

M. Duhamel made certain experiments to ascertain what advantage this method had over the usual way of spinning by the bight, and the result did not warrant him in recommending its adoption where the men had been accustomed to the other mode.

1805. October 30th, Mr Huddard took another patent for improvements in the manufacture of large cables and cordage in general. This invention consisted of a machine for twisting into ropes the strands formed by the machinery formerly invented by him, and resembled in some parts the machine of Mr Cartwright, called the cordelier.

In Mr Huddard's machine the three strands were wound on their separate reels, which were hung in frames having a motion round their own axes, so as to give hardening to the strands; and also a motion round a common centre in an opposite direction, in order to combine the strands into a rope. On the end of the axis round which the reels were carried for the last-mentioned purpose, the top was fixed, having in it three holes for the strands, and behind the top the rope was passed round three whirls, in such a manner as to regulate its tension while twisting.

1805. November 16th, Mr Curr secured by patent an invention of a method of laying or putting together the strands which form a rope.

The invention consisted, first, in so proportioning the teeth of the wheel at the upper end of the walk which twists the strands, to the teeth of that of the lower end which closes the rope, that the workmen, by keeping time with each other in their heaving round the winches of their respective wheels, would give the proper amount of hardening twist to the strands and closing twist to the rope; and, second, in regulating the motion of the laying-top, by having attached to it the end of a line or wire which is wound on a reel fixed to one of the wheels of the sledge, and made to move with a certain velocity according to the size and intended hardness of the rope.

1806. August 9th, Mr Ralph Walker of Blackwall took out a patent for a new mode of making ropes and cordage, applicable to the making of ropes and cordage of any size.

The machinery for effecting these purposes is on the same principles as many of those already described; but the arrangement of the parts is different, and very ingenious. In place of the reels with their yarns being hung on the face of three revolving discs, as in Mr Chapman's machine, they are arranged on the surface of three cylindrical flyers, and the yarns are carried over rollers in the inside of the cylinders, and conveyed to their axes at one extremity, where they are compressed by passing through a hole. These cylinders, like the discs, revolve round their axes, and twist the yarns at that point of the axis where they pass through; and they also revolve round a common axis, which is the main shaft of the machine. When the strands leave the cylinders they are guided by pulleys to a point in the main shaft, where they are formed into a rope. The patentee also describes a manner of tarring the yarns previously to their being wound upon the reels. In this case the tar in the kettle is heated by steam, and the yarns are passed through the kettle under a large roller which keeps them immersed. Engravings of all the machinery may be found in the Repertory of Arts, 2d series, vol. xxvi.

1806. In this year Mr Curr took out a patent for proportioning the number of twists in the yarns to the length, moved by the spinners, so that they might elongate equally on being untwisted in forming the strand. To effect this purpose he had a cord wound upon a barrel attached to the spinning-wheel, and receiving a determinate motion from it; the end of this cord, when the spinners were going to set off, was attached to any one of them, whose speed could thus be regulated by the unwinding of the cord, and the other spinners had to keep pace with him.

1807. October 30th, Messrs Chapman obtained a patent for a method or methods of making a belt or flat band of rope for mining and other purposes. This invention consisted in the combination of two or any greater number of the strands of shroud laid-ropes placed side by side so as to form any determinate breadth of belt or band; and in a locomotive machine for stitching or riveting them together when stretched at full length.

1808. June 25th, Mr S. Gadd took a patent for a method of forming ropes, which consisted in twisting the threads together in pairs, and forming the strands of these doubled threads.

1808. June 28th, Mr John Hall took a patent for regulating the twist of the thread in spinning, by means of an endless band traversing the walk, and moved with a given speed by pulleys fixed on the head of the spinning-wheel. To certain parts of this band marks are attached. When one of these marks is at the wheel, a spinner sets on, and in spinning keeps pace with the motion of the band, as indicated to him by the mark.

1828. September 4th, Mr Robertson took a patent for im-

Rope-making.

provements in the manufacture of hempen rope or cordage. The improvements consist in impregnating the yarns with tannin, by steeping them in an infusion of oak-bark, catechu, sumach, or valonia, previous to their being twisted into cordage.

1832. February 1st, Mr James Lang, flax-dresser, Greenock, obtained a patent for such improvements in the construction of the gill spreading or drawing heads, and roving or spinning frames, as adapted them for the spinning of rope-yarns. Fig. 14 shows a side view, and fig. 15 a top view, of the first drawing or spreading machine; and fig. 16 is a diagram illustrative of its mode of action. The same letters refer to the same parts in all the figures. Here *a* is a portion of a board called the spreading-board. Over the surface of this board an endless band of leather travels, in the direction indicated by the arrow; and on this band the hemp to be operated upon is spread. By the motion of the band the hemp is carried forward until it is taken hold of by the feeding rollers *bb*, by the motion of which it is carried onwards to be acted on by the gills or travelling hackles *ccc*; and the gills are fixed to slips of brass screwed to bars which extend across the machine, as seen in fig. 15. These bars pass through grooves formed in the links of an endless chain, by the motion of which they are carried round; and their ends move in peculiarly formed slits in the framing of the machine, by which they are confined to their proper course. By the gills being made to move faster than the surfaces of the feeding rollers, they pass through the hemp many times in the course of its passage across the space in which it is acted on by them, and they are thus enabled to split and straighten the fibres. The hemp now passes between the drawing rollers *ee*, the surfaces of which can be made to move from forty to sixty times faster than those of the feeding rollers, according to the material to be acted on. By them the hemp is drawn into a sliver of a certain state of fineness, and this sliver, after passing through the delivering rollers, falls into the can *g*. When a certain quantity of sliver is delivered into the can, a bell is rung by the machinery; the filled can is then removed by the attendant, and an empty one substituted. The filled cans are then conveyed to the second drawing machine, which differs from the first chiefly in being smaller, in having no spreading-board, and in having a double set of rollers and gills in the width, as will be seen by the top view, fig. 17. The cans containing the slivers from the first drawing machine are placed at the end of this, in such number as may be required, and many slivers are then passed together through each set of feeding rollers. After having been acted on by the gills and the drawing rollers, the slivers may be delivered separately, or they may be combined, as shown in the drawing, by passing through a tray previous to entering the last pair of delivering rollers. The slivers, after having been subjected to a third drawing, in a machine the parts of which are still finer than those of the second machine, are carried to the roving or spinning machine. This machine has feeding rollers, gills, and drawing rollers similar to the drawing machines; but the parts are still finer than those of the last machine. In fig. 18 the spinning apparatus is shown. The slivers, on leaving the drawing rollers, pass into the trumpet-mouthed tubes *aa*. The upper part of these tubes is in two halves, one of which is fixed to the cross rail of the machine, while the other is pressed against it by means of a spring, in such a manner as gently to compress the sliver on entering the tube. The bottom of the tube is set into another tube serving as a socket, and into this last tube discs of felt or cloth are put, through which a slit is made for the reception of the thread, which is thus com-

Fig. 14.

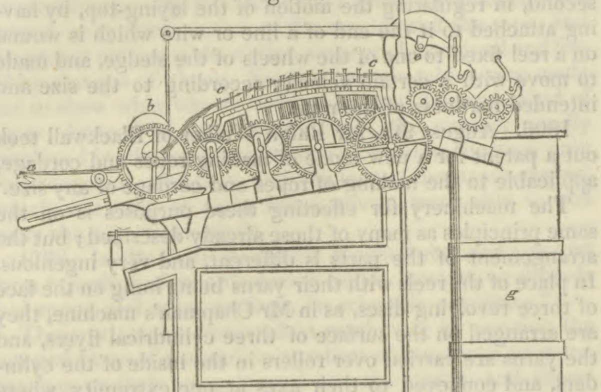


Fig. 15.

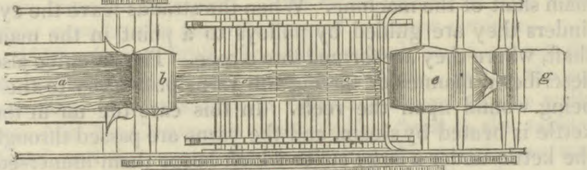

Fig. 16.

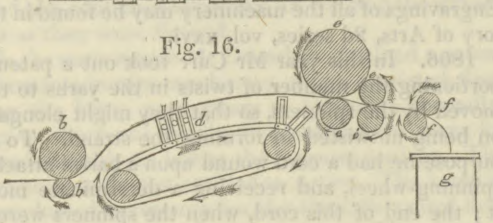

Fig. 17.

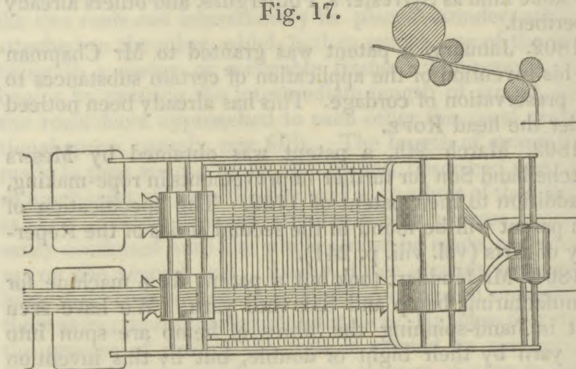

Fig. 18.

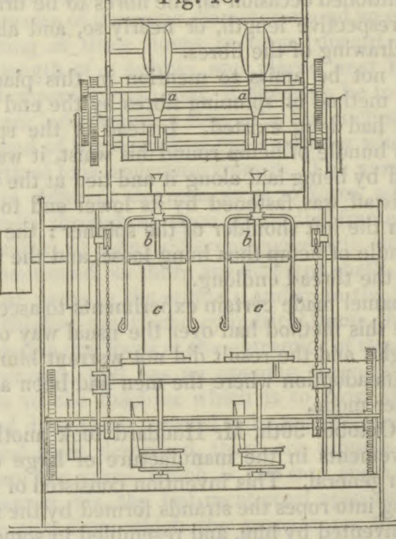

pressed and smoothed in the same manner as by the cloth in hand-spinning. From these tubes the threads are led to the flyers *bb* and bobbins *cc*, as in the ordinary spinning apparatus. Any degree of twist and of tension during twisting can be given to the yarn, by making the bobbins take up more or less of it for each revolution of the flyer; and this is simply effected by means of a drag formed of two steel springs fixed to the bobbin-rail. The ends of the springs partly embrace a peculiarly-formed pulley attached to the bottom of the bobbin, and by means of a pinching screw they can be made to bear with a greater or less degree of pressure on this pulley, and, according to the amount of pressure, the motion of the bobbin is in a greater or less degree retarded.

These machines differ from those in common use chiefly in the following particulars: 1st, In the distance between the feeding rollers and drawing rollers being capable of alteration, to suit longer or shorter hemp, by means of the grooves in the framing of the machines, seen in the side view, fig. 14; 2dly, in making the yarn to pass through the compressible tubes and the felt discs, which act in a manner analogous to the cloth in the grasp of the workman in hand-spinning; 3dly, in the power which the manufacturer has in regulating the tension and twist of the yarns while forming, by means of the drag applied to the bobbins.

The yarn produced by this machine is of excellent quality, and is much stronger than hand-spun yarn, as appears from certain experiments made for the purpose of testing them; the result showing, "that the patent-spun yarns are stronger than those of equal grist when spun by hand, and from the best staple or long hemp, by fifty-five per cent."

Mr Lang's machinery has in consequence been adopted by some of the most extensive rope-manufacturers in Great Britain.

1832. August 8th, Mr Crawhall obtained a patent for an improvement in the manufacture of flat rope, such as is used in mines. It will be remembered that in Mr Curr's patent, the method described of forming these bands was by sewing several ropes together side by side; and the improvement of Mr Crawhall consists in adding such wheels to the ordinary rope-work machinery as to enable it to make four ropes of the same size, of the same material, twisted in the same manner, and at the same time. By this equality of the ropes greater strength is insured; and they are put together by sewing or plaiting, as in the other patents.

1832. September 22d, Mr J. H. Kyan obtained a patent for the application to cordage of his now well-known process of steeping materials in a solution of deuto-chloride of mercury for the purpose of preserving them.

1833. May. Mr Norvel of Newcastle at this time took out a patent for machinery for rope-making. In this machinery the bobbins are, like Mr Walker's, arranged on the surface of cylindrical flyers, and in some of its other parts there is a resemblance to that of Mr Chapman; but there is much that is new, and the general arrangement appears to be excellent.

1838. August 8, a patent was obtained by Mr John Stewart, rope-manufacturer in Glasgow, for machinery for spinning yarn, and forming lines, cords, and ropes.

In figs. 19 and 20 a side and end view of the machine for spinning are exhibited. Here *aaa* is the framing; *bb'*, a fast and loose pulley on the principal shaft; *ccc*, bevel-wheels on the same shaft, gearing into pinions fixed on the frames *ddd*, which run in two bearings, one at the foot, and the other at *eee*, fixed to the rail of the frame; *fff* are sliver-cans, with projecting pins for hanging them in the hooks of the frames *dd*, so that any can may be shifted without disturbing the machinery; *gg* is a roller moved by a belt on the principal shaft, round which roller a turn of the thread is taken as it comes from the cans, and the motion of the roller, which may be increased or diminished at pleasure, draws the thread away from the can more or less rapidly. The action of the machine will now be easily understood. The cans having been filled with sliver at the common drawing-frame, are hung in the hooks of the frames; on motion being communicated to the machine, the frames are turned round, and twist the sliver into a thread; and as it is twisted, it is drawn away by the roller.

Fig. 19.

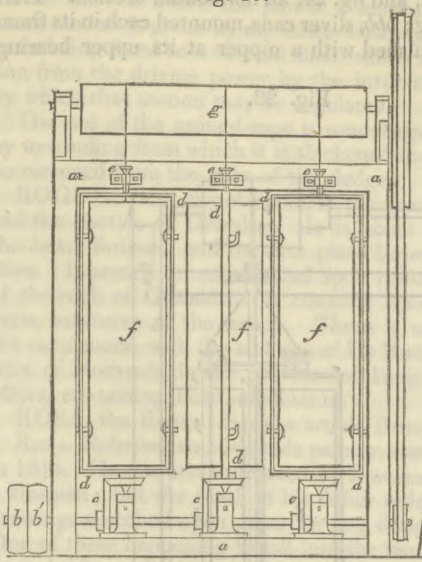

Fig. 20.

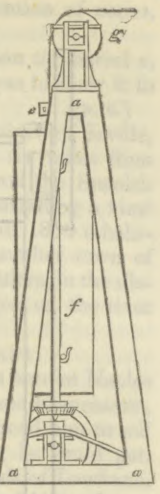

Fig. 21.

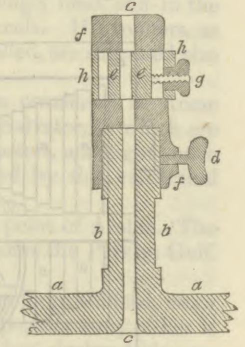

Fig. 22.

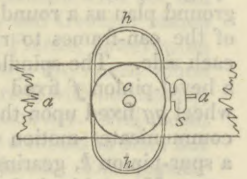

An essential part of the machine remains yet to be described. This is the nipper, or apparatus for holding tightly and regulating the twist of the sliver; one of these is fixed to each frame above its upper bearing. Fig. 21 is a section, and fig. 22 a plan, of one of the nippers to a large scale. In it *aa* is a part of one of the frames, *bb* the upper bearing, *cc* the hole through which the sliver passes, *d* a pinching screw to fix the nipper in the top of the frame; the part *e* works through a parallel mortise cut through the part *ff* of the nipper. By turning the nut *gg* the part *ee* is thrust into the mortise, so as to allow the sliver to pass through *cc* with more or less freedom, as may be required. Any irregularity in the thickness of the yarns is provided for by the spring *hh*, which allows *e* to yield a little when a part of the yarn happens to be thicker, or forces it inwards when any part happens to be smaller, than the general size, while the steady pressure is maintained by means of the nut *gg*. Through this part of the apparatus, then, the end of the sliver is put previous to being carried to the roller, and it is between this and the roller that the sliver receives its twist to convert it into a thread or yarn. When the yarns leave the roller they are wound on bobbins, or made use of in some other manner. The patentee describes a method of putting a slight twist into the slivers before the cans are hung in the frames of this machine. He also describes a modification of the frame, in which, in place of the cans, bobbins may be used; and he describes an apparatus for filling the bobbins. His machinery for forming lines, cords, strands, and ropes is represented in fig. 23, a vertical, and fig. 24, an horizontal, section. Here *aaa* is the framing; *bbb*, sliver cans, mounted each in its frame *ccc*, which is furnished with a nipper at its upper bearing. These can-frames run in brackets *dd*, *d'd'*, fixed upon an upright spindle *ee*; the bottom bracket *dd* is shown in the ground plan as a round plate, and the parts for the pivots of the can-frames to run in are raised upon it partly on each side. The spindle *ee* is made to revolve by means of a bevel-pinion *f* fixed upon it, which pinion gears into a wheel *gg* fixed upon the shaft *hh*. A belt from the pulley communicates motion to the main shaft *hh*, which carries a spur-pinion *k*, gearing into a wheel *l* fixed on the shaft *mm*. Upon this shaft the cone *nn* is fixed, which by a belt drives the cone *o*, running loose upon the main shaft *h*. Upon the large end of this cone the bevel-wheel *p* is either cast or fixed; and this gears into the pinion *q* fixed to the wheel *r*, the teeth of which are in its inner edge. This wheel with its pinion turns on the spindle *ee*, and its teeth gear into spur-pinions *ss*, fixed on the bottom of the can-frames. From the nippers at the top of the can-frame, each sliver is conducted to a separate hole near the top of the spindle *ee*; these holes run upwards in an angular direction from under the bracket *i*, and meet in one which is carried to the top of the spindle, where is fixed a nipper similar to those of the can-frames. The roller *v* is for the purpose of pulling away the strand, cord, or rope, as it is formed; and in this case is made slightly conical, so that by shifting it along its shaft, the speed with which it draws may be varied. The action of the machine will be easily comprehended. By the revolution of the spindle *ee* the can-frames are carried round a common centre; and as they turn they receive a motion, each round its own axis, by means of the wheel *r* and the pinions *ss*. If sliver be put into the cans and carried through their nippers, they will be twisted into yarns between the nippers and the holes in the upright spindle, and by the revolution of the spindle they will be combined so as to form a strand or cord. If in place of slivers strands be used, the result will be a rope. The patentee further describes machinery for the formation of flat ropes, or bands for mines and the like purposes.

Fig. 23.

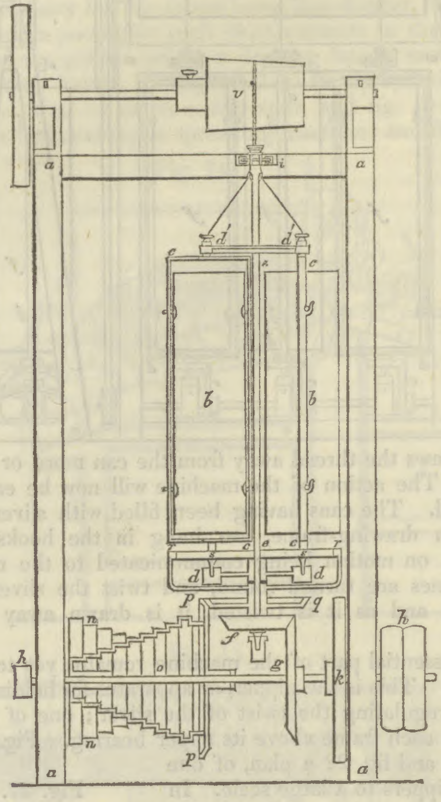

Fig. 24.

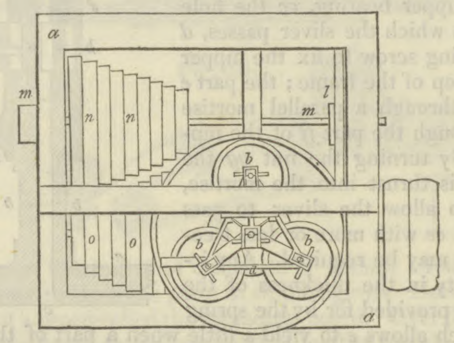

Having thus, as far as in our power, given an account of the progressive improvement of the art by the application of machinery, we shall conclude with a description of the most improved forms of machines and apparatus used in laying ropes in the present day.

When the yarns have been spun upon Mr Lang's or other spinning machines, or by hand, they are wound from the bobbins in a haul, upon a large octagonal reel about eight or nine feet diameter: the number of yarns in the haul are, of course, regulated by the conveniences of the manufactory. The haul is then passed from this reel through the tar-kettle, and, after undergoing the action of the nippers, is again wound upon a similar reel. From this reel the yarns are wound singly upon the reels or bobbins to be used in the laying. The bobbins, with their yarns, are then hung in frames, and the further machinery used is an improved form of Mr Chapman's locomotive apparatus. The whole arrangement of these parts will be better understood from the drawings. In the drawings the connection of the different parts with the moving power is not shown. This may be steam, water, or any other power, and may be placed in any convenient situation, so as best to serve all the purposes of the establishment.

Figs. 25 and 26 show the general arrangement of the winding apparatus; fig. 25 an end view, and fig. 26 a back view, of a portion of the winding-table. *aa*, reel about eight feet diameter, on which the haul is wound; *bb*, frame containing eight bobbins or reels *ccc*, fastened on vertical spindles *dd*, on the lower end of which the pulleys *ee* are fixed; on the horizontal shaft a corresponding number of pulleys are fixed, to drive those of the vertical shaft by belts. One end of the horizontal shaft carries a fast and loose pulley *g*,

Fig. 25.

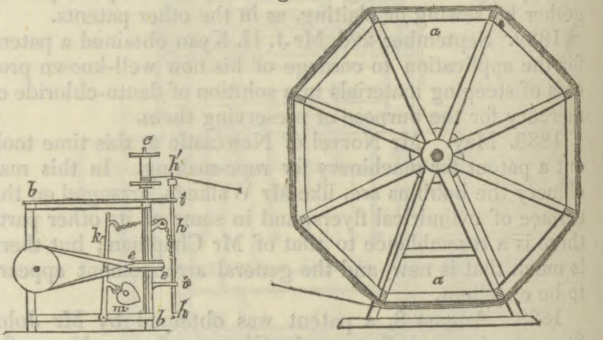

Fig. 26.

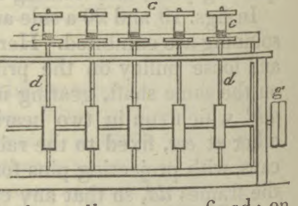

to which motion is given by a belt from the driving power. The apparatus for spreading the yarns on the reels consists of a rail *h'*, with loops or eyes opposite to each reel: through these eyes the yarns are passed. The rail is supported by two upright rods *h*, *h*, which slide through holes in the brackets *i*, *i*. To these rods the alternating motion is given by a chain connecting them with the lever *k*, which is wrought by the heart-wheel *m*. Figs. 27, 28, 29, show the arrangement of the apparatus for twisting the strands, and laying them into a rope. *aa* the reel-frame; *bb* the register-plate, through the concentric circles of holes of which the yarns are put. These holes are seen in the detached front-view of the plate at B. Immediately behind the plate the yarns are passed through the press-blocks, one of which is figured detached at C. They are then hung on the hooks of the sledge *cc*. These hooks are on the prolonged axes of pinions driven by a spur-wheel *d*, which again is driven by the mitred wheel *e*. This wheel can be connected with either of the wheels *f* and *g*, by means of a clutch wrought by the lever *h*. On the end of the axes of these mitre-wheels the pinion *k* is fixed, and receives motion from the spur-wheel *l*, fixed on the axis of the gub-wheel *m*. Round the gubs of this wheel a turn of the endless band *nn*, which traverses the walk, is passed, and gives motion to the machinery. On the other end of the gub-wheel axis a pinion *o* is fixed, which drives the spur-wheel *p*. On the middle of the axis of this wheel another gub-wheel is fixed; round it a turn of the ground-rope *q* is passed, and by this the sledge is moved progressively backwards: the wheels of the sledge are flanged, and run upon a railroad *r*. When the endless band is set in motion after the yarns have been hung on the hooks of the sledge, the sledge travels backwards at a rate which may be proportioned to the twist required to be given, by the gubs of the ground-rope wheel being made to shift further from or nearer to its centre, so as to move the sledge through a greater or less space for each revolution of the hooks. When the sledge has reached the foot of the walk, the strands are hung together on the centre-hook of the wheel, and by means of the lever *h* the motion is reversed; at the same time the yarns are cut over by the tackle-board, and hung on the hooks *s*, *s*, *s*, at the fore end. To these motion is given by the spur-wheels *t*, *t'*, the latter of which may be driven either by the pinion *u* and spur-wheel *w*, or directly by the pinion *x*, as a quicker or slower motion is required. To the shaft on which the pinion *x* and spur-wheel *w* are fixed, motion is given by the mitre-wheels *y*, *y'*, *y'*, the two latter being fixed to a vertical shaft, which receives its motion from the driving power by the intervention of cones, by which that motion may be regulated.

Fig. 27.

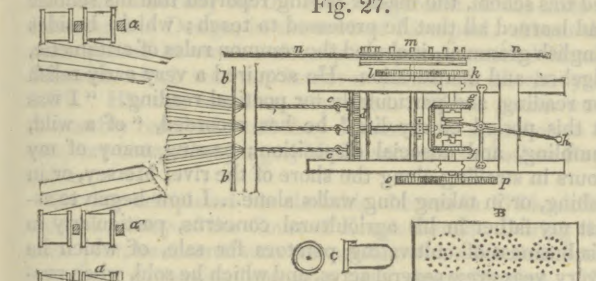

Fig. 28.

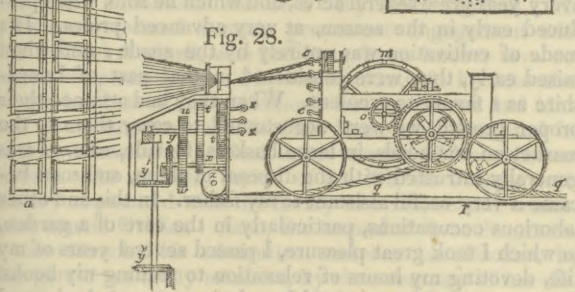

Fig 29.

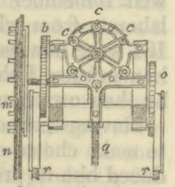

The end of the ground-rope is wound upon the barrel *z*, by unwinding from which it is slackened so as to allow it to be removed from the gubs of the sledge. (B. S.)

ROQUE, St, a city of Spain, in the province of Seville, and the partido of Gibraltar. It is about six miles from the latter fortress, and the first place beyond the Spanish lines. It stands on an elevated spot, commanding a view of the rock of Gibraltar. It contains about 1800 inhabitants, exclusive of the troops. There is another town of the same name, with the addition of De Rumiera, in the district of Montania, in the province of Burgos, on the river Miera, containing 1250 inhabitants.

ROSA, the Rose. See the article Botany.

Rosa, *Salvator*, an admirable painter, was born at Naples in 1614. He was first instructed by Francesco Francazano, a kinsman; but the death of his father reduced him to sell drawings sketched upon paper for any thing he could get. One of these happening to fall into the hands of Lanfranc, he took him under his protection, and enabled him to enter the school of Spagnoletto, and to be taught by Daniel Falcone, a distinguished painter of battles at Naples. His pieces are exceedingly scarce and valuable; one of the best of them being that representing Saul and the witch of Endor, which was preserved at Versailles. He died in 1673; and as his paintings are in few hands, he is more generally known by his prints, of which he etched a great number. He painted landscapes more than history; but his prints are chiefly historical. The principal landscape of this master is a noble picture at Chiswick. We are told that he spent the early part of his life in a troop of banditti; and that the rocky desolate scenes in which he was accustomed to take refuge, furnished him with those romantic ideas in landscape, of which he is so exceedingly fond, and in the description of which he so greatly excels. His robbers, as his detached figures are commonly called, are supposed also to have been taken from the life.

Amongst the musical manuscripts purchased at Rome by Dr Burney, was a music-book of Salvator, in which are many airs and cantatas of different masters, and eight entire cantatas, written, set, and transcribed by this celebrated painter himself.

ROSALGATE, the most eastern point of Arabia. The coast turns to the north-west, till it joins the Persian Gulf. Long. 60. 10. E. Lat. 22. 20. N.

ROSAMOND, daughter of Walter Lord Clifford, was a young lady of exquisite beauty. The popular story of her is as follows. Henry II. saw her, loved her, declared his passion, and triumphed over her honour. To avoid the jealousy of his queen Elinor, he kept her in a wonderful labyrinth at Woodstock; and by his connection with her had William Longsword earl of Salisbury, and Geoffrey bishop of Lincoln. On Henry's absence in France, however, on account of a rebellion in that country, the queen found means to discover her; and, though struck with her beauty, she recalled sufficient resentment to poison her. The queen, it is said, discovered her apartment by a thread of silk; but how she came by it is differently related. This popular story is not however supported by history. She was buried in the church of Godstow, opposite to the high altar, where her body remained till it was ordered to be removed with every mark of disgrace by Hugh bishop of Lincoln in 1191. She was, however, considered as a saint after her death.

ROSAS, a fortified city of Spain, in the province of Catalonia, and district of Gerona. It stands on an elevation on Cape de Creus, on the Mediterranean Sea, and commands the celebrated bay of that name where so much valour was displayed by our ships of war, whose boats' crews boarded and captured or destroyed many of the enemy's ships during the long hostilities. The bay has a lighthouse, and is protected by two strong forts, and is one of the most secure anchorages on that coast. The city contains 1900 inhabitants, who in time of peace depend chiefly on the fisheries. Long. 3. 31. 2. W. Lat. 42. 16. 6. N.

ROSCIUS, Q. a celebrated comic actor, who is spoken of in terms of the highest commendation by Cicero. The exact period of his birth is unknown; but he must have been somewhat older than Cicero (born B. C. 106), as he had already earned a high reputation before the death of Sulla, B. C. 78. His subsequent career was said to have been predicted by a strange occurrence whilst he was still a child. His early years were spent at Solonium, near Lanuvium; and whilst he was sleeping in his cradle, a serpent entwined itself round his body without injuring him. This circumstance in the life of the actor was afterwards represented by the artist Praxiteles, and celebrated by the poet Archias. The orator afterwards remarks, that it seems ridiculous that the gods should predict the future fate of an actor, whilst they neglected statesmen and heroes, whom the world admired. Of his education we know nothing, except that he and Æsopus the tragic actor used to attend the forum when Hortensius the orator pleaded, that they might imitate on the stage what they admired in him. He had a particular squint of the eye, but this was of course concealed by the mask he wore. His private character was highly respected, and Cicero remarked that he was such an artist that he seemed the only one fit to appear upon the stage, and yet so excellent a man that it was beneath his dignity, which he thought worthy of the senate. He used to contend with Cicero which of them could represent the same sentiment in the greatest variety of ways, he by acting, and Cicero by his eloquence. So high an opinion did he entertain of his profession, that he wrote a work comparing it with oratory. He gave lessons in elocution, and used to say that he never had a pupil whom he could altogether approve of. His gains as an actor are variously stated, by Macrobius at 1000 denarii (L.32. 5s. 10d.) a day; and by Cicero at 600,000 sesterces for ten years (L.48,434. 10s.), which would make it somewhat less than L.5000 a year; but for the last ten years he had refused to receive this pension from the Roman people. He had a dispute with one Fannius Chœrea respecting a slave, of whom they were joint owners, and he was defended by Cicero; but at what time this took place we have no means of judging. Only a part of the speech has been preserved. He died a little before the time (about B. C. 61) that Cicero delivered his oration in defence of Archias.

ROSCOE, William, a distinguished writer, was born at Liverpool on the 8th of March 1753. He was the only son of William Roscoe, who then kept a public-house called the Bowling Green, and who is described as a man below the middle stature, but of remarkable bodily strength and activity; of much vivacity of temperament, and greatly attached to field-sports and other amusements, for which his son never acquired any relish. He had also an only daughter, who became the wife of Daniel Daulby, Esq. With the charge of his public-house he united that of a market-garden; but during his declining age, he retired to Charnock, his native place, and was for many years supported by his son. Two years before his death, Mr Roscoe removed him to his own house at Birchfield, where his latter days were soothed by the assiduous kindness of his two children. Having reached an advanced age, he died in 1796. His wife, whose name was Elizabeth, is said to have been a woman of a superior mind and of warm affections, and to have exercised over the character of her son an influence, of which the effects were never obliterated to the latest period of his life.

The first elements of learning he acquired under the tuition of a schoolmistress; and at the age of six, he was removed to a day-school kept by Mr Martin in Paradise Street. After an interval of about two years, he became the pupil of Mr Sykes, who, in the same house, kept a school for writing, arithmetic, and English grammar. He had a numerous seminary, and was considered as a good instructor in his own department. At the age of twelve Roscoe quitted this school, the master having reported that his scholar had learned all that he professed to teach; which, besides English grammar, included the common rules of arithmetic, algebra, and mensuration. He acquired a very early relish for reading, and particularly for poetical reading. "I was at this period of my life," he has recorded, "of a wild, rambling, and unsocial disposition; passing many of my hours in strolling along the shore of the river Mersey, or in fishing, or in taking long walks alone....I now began to assist my father in his agricultural concerns, particularly in his business of cultivating potatoes for sale, of which he every year grew several acres, and which he sold, when produced early in the season, at very advanced prices. His mode of cultivation was entirely by the spade; and when raised early, they were considered in that part of Lancashire as a favourite esculent. When they had attained their proper growth, we were accustomed to carry them to the market on our heads, in large baskets, for sale, where I was generally intrusted with the disposal of them, and soon became a very useful assistant to my father. In this and other laborious occupations, particularly in the care of a garden, in which I took great pleasure, I passed several years of my life, devoting my hours of relaxation to reading my books. This mode of life gave health and vigour to my body, and amusement and instruction to my mind; and to this day I well remember the delicious sleep which succeeded my labours, from which I was again called at an early hour. If I were now asked whom I consider to be happiest of the human race, I should answer, those who cultivate the earth by their own hands."

Having reached his fifteenth year, he found it expedient to make choice of a profession. His love of reading induced him to prefer the avocation of a bookseller; but he was disappointed in his expectation of finding it altogether pleasant, and after a trial of a month, he returned to his rustic labours. In the course of the ensuing year, 1769, he was articled to a young attorney, who died before the completion of his clerkship. The remainder of it was passed in the office of Mr Peter Ellames, who was eminent in his profession, and who was much satisfied with his pupil's talents and industry. During this period, he still continued to reside with his father, but he had previously the misfortune to lose his mother. Although very punctual in his attention to business, he always found some precious intervals of leisure for the cultivation of his literary talents; and his early love of poetry had its usual effect in purifying and refining the taste. His chief favourite was Shenstone, with whose elegant simplicity he appears to have been greatly captivated. He cultivated an intimate friendship with other ingenuous youths, who cherished the same love of literature. In conjunction with two of these, William Clarke and Richard Lowndes, he applied himself to the study of the ancient languages; and with these individuals, to the close of their lives, he continued in habits of the strictest intimacy. They had another associate, who was capable of directing as well as participating in their studies. This was Francis Holden, a young man of uncommon talents, who was an assistant in his uncle's school, where it was his business to teach, not only mathematics, but likewise the Greek, Latin, Italian, and French languages. They were accustomed to meet early in the morning, and to pursue their classical studies till the hours of business called them to less genial avocations. It was the example of Holden that prompted him to begin the study of the Italian language, in which he at length attained to so great proficiency.

He thus continued to improve his taste, and to enlarge his fund of knowledge. From a fervent admiration of poetry there is generally an easy transition to the composition of poems. He wrote many verses in his early youth; and at the age of twenty, he printed an Ode on the Foundation of a Society for the Encouragement of the Arts of Painting and Design, in the town of Liverpool. About the same period he wrote a descriptive poem, entitled Mount Pleasant, which was not however published till the year 1777. His ode was then reprinted. These poems were favourably received; and they obtained the approbation of two very competent judges, Mr Mason and Sir Joshua Reynolds.

Having completed his clerkship, he was in 1774 admitted an attorney of the Court of King's Bench. During the same year, he entered into partnership with a Mr Bannister, but their connexion was of a very short duration. He afterwards formed a more permanent engagement with Mr Samuel Aspinall, who had long been known as a respectable practitioner. He was assiduous in his attention to the business of his profession; but he did not find himself constrained to abandon his literary studies, and he thus continued the gradual improvement of his excellent talents. At an early period of his life, he became intimately acquainted with the family of a respectable tradesman named Griffies. Jane, the second of three daughters, "soon attracted his admiration, and won his affection, by her gentle yet lively manners, by the sweetness of her disposition, and by the many admirable qualities of her truly feminine mind. Although the state of his circumstances at this time gave little promise of an immediate union with the object of his attachment, it was not the wish, and perhaps it was scarcely in the power, of one possessing the frank and ardent character of Mr Roscoe, to conceal from her the feelings she had inspired. From that moment, to the close of his long and eventful life, he never found reason to regret, for one instant, the judgment of his youth." A considerable interval elapsed before they could prudently fulfil their engagement; but his professional emoluments gradually became more ample, and they were married on the 22d of February 1781. Their union was attended with more than common felicity.

The African slave-trade was now in its fullest vigour; and as it formed a very material part of the commerce of Liverpool, the great body of the inhabitants were interested, either directly or indirectly, in the continuance of this detestable traffic. For any individual to raise a warning voice against it in such a community, required no small portion of moral courage. The generous feelings and manly character of Mr Roscoe urged him to take a very prominent share in those proceedings which finally led to its suppression; a measure which reflected so much honour on that administration which included Fox, Grey, Holland, and Erskine. He composed, in blank verse, a poem entitled "The Wrongs of Africa;" of which the first part was published in 1787, and the second in 1788. It was translated into German by a clergyman named Kühn. In 1787 he likewise published "A general View of the African Slave Trade, demonstrating its Injustice and Impolicy: with Hints towards a Bill for its Abolition." This seasonable tract was followed in 1788 by "A Scriptural Refutation of a Pamphlet lately published by the Rev. Raymond Harris, entitled 'Scriptural Researches on the Licitness of the Slave Trade': in four Letters from the Author to a Friend." Harris was a clergyman of the established church, but had been educated for the popish priesthood. Such talents as he possessed were employed in an attempt to prove that slavery, as a system, has obtained the divine approval; that God has sanctioned the principle of one portion of mankind treating another like beasts of burden. For his satisfactory refutation of this reverend apologist of such enormities, Mr Roscoe received the thanks of the London Abolition Committee. They likewise printed a new edition of his pamphlet, which was extensively circulated, and highly approved. In 1792 he published "An Inquiry into the Causes of the Insurrection of the Negroes in the Island of St Domingo." Of this insurrection the advocates of slavery had endeavoured to avail themselves, as a most powerful argument against the abolition; and he therefore performed another important service by exposing the fallacies of their reasonings and inferences.

In other public transactions of that eventful period, he likewise felt a deep interest. On all subjects his sentiments were humane and liberal. With some of the most enlightened men of the kingdom, he contemplated the French revolution as a glorious event; and his feelings of exultation were expressed in more than one poetical effusion. The atrocities which ensued were revolting to every well-constituted mind: but he still continued true to the great cause of civil and religious liberty, and in the midst of the apostacy of one party, and the phrensy of another, he continued to avow and to maintain those principles which established, and which alone can uphold the British constitution. The most conspicuous apostate of that period was Edmund Burke, who deserted his former principles and his former friends, and made a general declaration of war against all those who breathed an ardent wish for the political or social melioration of mankind. The powers of his eloquence were exerted, with a morbid and phrensied fervour, against those who differed from him after he began to differ from himself; and when we consider that he was instrumental, beyond any other individual, in promoting war abroad, and despotism at home, it may without any breach of charity be affirmed, that his memory deserves the execration of posterity. In the year 1796 Roscoe published "Strictures on Mr Burke's Two Letters, addressed to a Member of the present Parliament." Here he animadverts on the exaggerated statements of his adversary, and exposes the real object of his recent publications, the suppression of all liberal and independent speculation on the subject of politics. This famous orator was evidently disposed to acquiesce in the opinion of Bishop Horsley, that the people have nothing to do with the laws but to obey them. At an earlier period, 1791, Roscoe had printed a merry ballad concerning "The Life, Death, and wonderful Achievements of Edmund Burke;" and had adorned it with a frontispiece etched by himself, and representing Burke equipped like a knight-errant, and assaulting Fox in the House of Commons.

About this period his mind was vigorously devoted to an undertaking of a more important nature. The plan of preparing a biographical account of Lorenzo de' Medici had occurred to him at a very early stage of his literary career. He long continued to collect books, and to amass materials; and at the close of the year 1789, he communicated his design to his intimate friend Mr Clarke, who was then residing in Italy for the benefit of a milder climate. This gentleman had been engaged in commercial pursuits, but is said to have been skilled in ancient as well as modern literature. With great alacrity he undertook the task of exploring the archives and libraries of Florence, in quest of materials for the projected work; and the author acknowledged himself deeply indebted to the assistance which he had thus received. The sale of the Crevenna and Pinelli libraries enabled him to procure many rare books, for which he might otherwise have made a hopeless search. "The Life of Lorenzo de Medici, called the Magnificent," was at length published in the year 1796, in two volumes quarto. It was elegantly printed by John Maccreery, who, at his suggestion, had recently established a press in Liverpool. The success of this publication exceeded the most sanguine expectations which the author could have ventured to cherish. From the periodical critics he obtained ample praise. He received letters of warm commendation from men of rank and men of letters, with several of whom he had no previous acquaintance or correspondence. One of these was the eccentric earl of Bristol and bishop of Derry, who was then residing in Rome. He first applied to Mr Cadell, the bookseller, in order to ascertain the author's profession, resources in life, and what present of books, pictures, or statues, might be most acceptable to him. Dr Parr's fervent zeal in the cause of literature likewise prompted him to seek the correspondence of the elegant biographer. The first letter which he addressed to him contains the subsequent passage: "You will pardon my zeal, Sir, and you may confide in my sincerity, when I declare to you that the contents of your book far surpassed my expectation, and amply rewarded the attention with which I perused it. You have thrown the clearest and fullest light upon a period most interesting to every scholar. You have produced much that was unknown, and to that which was known you have given perspicuity, order, and grace. You have shown the greatest diligence in your researches, and the purest taste in your selection; and upon the characters and events which passed in review before your inquisitive and discriminating mind, you have united sagacity of observation with correctness, elegance, and vigour of style." The correspondence thus begun led to an intimate friendship. The work obtained a very high compliment from another individual, from whom it was less to be expected. Mathias so completely overcame the violence of his political animosities, as to bestow this eulogium on the author:

> But hark! what solemn strains from Arno's vales
> Breathe raptures wafted on the Tuscan gales!
> Lorenzo rears again his awful head,
> And feels his ancient glories round him spread;
> The Muses starting from their trance revive,
> And at their Roscoe's bidding wake and live.

To these lines, in his Pursuits of Literature, he has subjoined a long note, which contains the subsequent passage: "I have not terms sufficient to express my admiration of his genius and erudition, or my gratitude for the amusement and information I have received." An intercourse of civilities with the anonymous writer was a very natural result; and he was afterwards extolled by Mathias in Italian verse as well as prose.

The first edition of this work was printed at the expense of the author; but soon after its appearance, Cadell and Davies offered him no less a sum than L.1200 for the copyright. Of this liberal offer he did not hesitate to accept; and little doubt can be entertained that the booksellers found it a very advantageous transaction. The fourth edition, in three volumes octavo, was printed in 1800. In other countries, the success of this book was equally brilliant. Three editions were speedily circulated in America. The work, translated into German by Sprengel, was published at Berlin in 1797. In 1799 a French translation, by François Thurot, was published at Paris. During the same year, an Italian version, by the Cavaliero Gaetano Mechirini, made its appearance at Pisa, in four volumes octavo. It was undertaken at the suggestion of the elegant Fabroni, who had himself published a Latin life of Lorenzo, which he intended to translate into his native language; but he was so much delighted with Roscoe's work, that he abandoned his design, and recommended the other task to Mechirini. In the course of the ensuing year, he addressed a very gratifying letter to the author. Similar letters were addressed to him by Bandini, the learned keeper of the Laurentian Library in Florence, and by the Abate Andres, a Spanish Jesuit, resident in Italy, and deeply skilled in Italian literature.

For the avocation of an attorney Mr Roscoe never had any hearty relish, and he finally relinquished it in the year 1796. With his last partner, Mr Lace, he made an arrangement which secured him some interest in the business; and during the following year he entered himself at Gray's Inn, with the view of being called to the bar. He kept Hilary term, but made no further progress in this new career, although, according to the opinion of his son, he possessed qualities which must in all probability have rendered his success certain. In conjunction with Mr Thomas Wakefield, he had in 1793 obtained a lease of an extensive tract of peat-moss in the vicinity of Manchester; and from the draining and improvement of this land he anticipated an ample return. In 1799 he purchased one half of the Allerton estate, a valuable property situate about six miles from Liverpool. Allerton Hall, which belonged to his portion, was originally built in the reign of James the First; but that structure had been partly taken down about the middle of last century, and a handsome stone-edifice had been erected in its place. The house was surrounded by gardens disposed in the old English taste, and was environed on every side with ample woods. Here it was his wish to spend the remainder of his days in studious retirement; but within the brief period of twelve months, he found himself deeply involved in the labours and anxieties of commercial life. The family of his intimate friend Mr Clarke, which had long been connected with an extensive banking-house at Liverpool, was at the close of the year 1799 placed in circumstances of considerable difficulty. "The aid of Mr Roscoe, as a confidential adviser, was requested by the partners, and he did not hesitate to lend his best assistance. Chiefly through his instrumentality, the difficulties which existed between the Liverpool bank and their London correspondents were removed, and it was the anxious wish of the latter, as well as the former, that Mr Roscoe should render his labours complete, by becoming an active partner in the banking-house at Liverpool." It was rather his friendship for the family of Clarke, than any motive more personal to himself, that induced him to embrace this offer.

By great and unremitting exertions, he brought the affairs of the house into a better train of management; and towards the close of the year 1800, he could again command some portion of leisure for his favourite pursuits. He had previously published "The Nurse, a poem translated from the Italian of Luigi Tansillo." This elegant version was favourably received, and it reached a third edition in 1804. But he had for some time contemplated a more magnificent undertaking, a life of Leo the Tenth; and on receiving, through the kindness of Lord Holland, some important and unpublished materials from Florence, he reverted to it with new ardour. "The History of the Life and Pontificate of Leo X." was published in four volumes quarto in the year 1805. It had been in the press upwards of two years. For one half of the copyright Cadell and Davies paid the sum of L.2000. This work, notwithstanding its great and varied merit, experienced a less favourable reception than its precursor. The author's brilliant success appears to have excited no small degree of spleen in some of the periodical critics, who accordingly treated him with little candour or courtesy. This production however, relating to a most important era in the civil, ecclesiastical, and literary history of Europe, was highly estimated by many very competent judges. The history of the revival of learning was itself a very extensive, as well as a very arduous field for disquisition. The history of the fine arts required knowledge and taste of a different denomination. The history of the reformation of religion involved many questions of subtle disputation, as well as many topics of character and conduct; and for a writer of great candour and discernment, it was scarcely possible to satisfy either the Papists or the Protestants. The Life of Leo, with the omission of the documents contained in the appendix, was speedily reprinted at Philadelphia; but the sale was not there so rapid as that of his former work. A German translation, by Professor Glaser, was published at Leipzig in three volumes octavo, which successively appeared in 1806, 1807, and 1808. A preface, notes, and disquisitions, were contributed by Henke. In 1808 a French translation, by P. F. Henry, was published at Paris, and a corrected edition appeared in 1813. An Italian version was subsequently undertaken by Count Luigi Bossi, who began by translating from the French. This work extended to twelve volumes octavo, published at Milan in 1816 and 1817. He added a variety of notes and documents illustrative of the text, together with numerous engravings of portraits and medals. The sovereign pontiff, Leo XII., inserted this translation in the catalogue of prohibited books, but in spite of his denunciation, 2800 copies of it have been dispersed in Italy, where the name of the elegant author continues to be held in no common estimation.

Soon after the appearance of his great work, he was suddenly induced to place himself in a new sphere of action. "Although from a very early period of life Mr Roscoe had taken a deep interest in public affairs, and had manifested, not only by his writings, but also by the part he had taken in promoting public meetings in Liverpool, the strong desire he felt to render himself useful to the country, he had yet never entertained the idea that he should be called upon to fill the responsible situation of a representative of the people. It was therefore with the greatest surprise that, on the eve of the general election in 1806, he received a requisition from a number of the most respectable burgesses of Liverpool, requesting him to come forward as a candidate for the representation of his native town." This requisition he received on the 30th of October; he issued his address to the electors on the following day, and the election commenced on the first of November. His two opponents were General Gascoigne and General Tarleton; of whom the former had represented the borough for ten, and the latter for sixteen years. They were both Tories, but with this difference, that Tarleton was a deserter from the Whigs. They were both supported by the corporation; but after a very strenuous contest of seven days, the election terminated in favour of Roscoe, who had nearly two hundred votes over Tarleton, and thirteen over Gascoigne. During the progress of the election, he had uniformly been the popular candidate; his success was hailed with the most enthusiastic rejoicings; and he was chaired through a greater concourse of people than the town had probably ever beheld on any former occasion.

Of the House of Commons he was not a silent member. He took a respectable share in various debates; and he had the high satisfaction of raising his voice in favour of the abolition of the slave-trade. He likewise made a judicious speech in support of Romilly's bill for subjecting real estates to debts of simple contract. The unhappy and inveterate prejudices of the king led to the dissolution of the ministry in the spring of 1807. On the 15th of April, Mr Littleton moved a resolution, expressing the regret of the house at the recent change in his majesty's councils; and Mr Roscoe then spoke with manly indignation against the conduct of Canning, who, in a previous debate, had thought proper to threaten the house, that if its members did not vote according to the will of the ministry, his majesty would be advised to appeal to the people, or, in other words, to dissolve his parliament. The parliament was dissolved, and the senseless cry of "No Popery," and "the Church in danger," resounded from one end of the island to the other. It was the peculiar infelicity and infatuation of the old king's administration, that he was uniformly averse from employing men who supported the principles which had placed his family on the British throne.

Mr Roscoe returned to Liverpool in the month of May, and, on approaching the town, was received by a numerous procession of friends, partly on horseback, and partly on foot. Their progress was speedily obstructed by large bodies of men, chiefly consisting of the crews of vessels recently engaged in the slave-trade, armed with bludgeons and other weapons, and disposed along the range of streets. The procession moved with difficulty, and not without danger. Many personal injuries were sustained on both sides; and if great forbearance had not been displayed towards the ruffianly assailants, the most fatal consequences might have ensued. When he reached the bank, and attempted to address the crowd, the clamour was so loud and unceasing that he found it impossible to obtain a hearing. He had honourably given a vote against the traffic in human flesh, and by that craft most of the disorderly multitude had their living. Disgusted at such a display of popular violence, he speedily declared his resolution of declining to offer himself as a candidate at the ensuing election; but he was nominated without his own consent, and the contest was protracted till the seventh day, when it terminated by the return of the two generals.

Although he thus ceased to be a member of parliament, he did not cease to take an interest in public affairs. In 1808 he published "Considerations on the Causes, Objects, and Consequences of the present War, and on the Expediency or the Danger of Peace with France." This was an able as well as a seasonable publication; but we cannot add, that it produced any extensive or speedy effects. The war, which had been carried on at such an enormous expense of blood and treasure, was profitable to an immense multitude of individuals: it served to extend the patronage and influence of the ministry; loans, contracts, and other contingencies, enriched one class of their adherents; an immense field of employment and promotion was opened in the army and navy; while another class of men, who were specially bound to act as messengers of peace, were too generally disposed to keep in the onward path of preferment by preaching in favour of "this just and necessary war." The real object of the war was a matter so extremely doubtful, that it was not unusual to hear a variety of objects specified by different individuals all equally fervent in the same cause. By one great personage, the hopeful project of restoring the Bourbons was doubtless contemplated as the great and paramount object. Roscoe's tract was published in January, and a fourth edition was sent to press before the end of that month. It was speedily followed by "Remarks on the Proposals made to Great Britain for opening Negociations for Peace, in the year 1807." The several tracts which he had published on such topics, were in 1810 collected into a volume bearing the title of "Occasional Tracts relative to the War." This collection, which includes several tracts that have not been enumerated, remains a monument of his wisdom, in the midst of the general phrensy which then prevailed. In 1812 he published "A Review of the Speeches of the Right Hon. George Canning on the late Election for Liverpool, so far as they relate to the Questions of Peace and Reform." Roscoe was an able and enlightened advocate of parliamentary reform, as of all other attempts to improve the general welfare. During this general election, some of the inhabitants entertained a plan of returning him free of expense. He was likewise solicited to allow his friends to put him in nomination at Westminster; but he had no inclination to resume his seat in the House of Commons. Some of the electors of Leicester, where any opposition to the prevalent corruption was nearly hopeless, nominated him as a candidate without his previous knowledge; and, under these peculiar circumstances, he obtained 412 votes, while the second of the successful candidates had only 967. This homage to an individual personally unknown, was paid to him as "the friend of peace, of reform, and of religious liberty." In his printed address to the independent electors of this borough, he expressed his "conviction that the great work, which must eventually produce the reformation and happiness of the people, was already begun." An eventful period of twenty years served to evince how well he had discerned the signs of the times.

The return of peace did not immediately produce all the benefits that were anticipated. The war-establishment, with its lavish profusion of expenditure, had long contributed to maintain an artificial state of things. When the war was at length brought to a termination, we were overwhelmed with an enormous national debt; and under such burdens as this debt imposed, it was difficult for manufactures and trade to find a favourable channel. The banking-house with which Roscoe was connected did not escape the commercial pressure of that period. Great exertions were made by the partners to avert the crisis by which they were threatened; but suspicions having been excited, large balances were suddenly withdrawn from the bank; and after struggling for a few days in the vain hope of supporting their credit, they were, on the 25th of January 1816, reduced to the necessity of suspending their payments. A committee appointed by the creditors reported that, after the liquidation of the debts, there would remain a surplus of L.61,144. The bank was never shut; and the house was allowed six years for discharging all the debts, with interest. Roscoe undertook the management of its affairs, and exerted himself with surprising energy. One of the greatest trials which he sustained, was the necessity of parting with his library, pictures, and other works of art, the valuable and cherished accumulation of nearly half a century. The auction of his library, which was sold by Winstanley of London, extended to fourteen days, commencing with the 19th of August 1816. It included rare and precious works in several departments, but was particularly rich in Italian literature. The sale of the books was immediately followed by that of the prints, which occupied eleven days, and, being divided into 1352 lots, produced the sum of L.1915. 1s. The drawings, consisting of 610 lots, and the paintings, of 156, were sold for L.2825. 19s.

In the midst of these vicissitudes and trials, which he endured with exemplary fortitude, he still retained his love of literature. In the establishment of the Royal Institution of Liverpool, he lent his effective aid. A plan for such an institution had in 1813 been written by Dr Traill, now professor of medical jurisprudence in the university of Edinburgh. The scheme was at length brought towards maturity; and, after an interval of four years, Mr Roscoe, as chairman of a committee, prepared an explanatory report. He was induced, though not without considerable difficulty, to compose and to deliver the inaugural address at the opening of the institution. The attendance was very numerous, and he received the most gratifying applause. On the ensuing day, he was requested by the committee to publish his discourse, and it accordingly appeared under the subsequent title: "On the Origin and Vicissitudes of Literature, Science, and Art, and their Influence on the present State of Society: a Discourse delivered on the Opening of the Liverpool Royal Institution, 25th November 1817." In 1819 he published his "Observations on Penal Jurisprudence, and the Reformation of Offenders." In 1822 appeared his "Additional Observations" on the same subject; and a third part followed in 1825. He afterwards published two tracts on the penitentiary discipline of the United States. In all his literary undertakings, he aimed at improving the morals and increasing the happiness of mankind.

In the mean time, the affairs of the bank had reached their final crisis. The partners found themselves unable to contend with the difficulties which beset and impeded their progress, and a commission of bankruptcy was issued in the year 1820. Having now withdrawn from business, he seems to have placed his chief reliance on the remuneration of his literary labours. Some of his friends privately raised the sum of L.2500, and vested it in trustees for the benefit of himself and his family. "The office of communicating to him this kind and liberal act, on the part of his friends, was confided to Dr Traill, who by his judicious representations, and affectionate remonstrances, succeeded in removing from the mind of Mr Roscoe the objections which he felt to incur obligations of so serious a nature." About this period, he found a pleasing employment in arranging and improving the library of Mr Coke, now earl of Leicester, and in preparing a catalogue of the numerous manuscripts. His visits to Holkham were rendered peculiarly pleasant; and this gentleman, as we are informed, "conferred upon him obligations of no ordinary nature." His literary ardour was still unabated; and in 1822 he published an octavo volume, under the title of "Illustrations, Historical and Critical, of the Life of Lorenzo de' Medici, called the Magnificent; with an Appendix of original and other Documents." An Italian version, exclusive of the appendix, was published at Florence by Pecchioli in the course of the following year. In 1822 he likewise published a "Memoir of Richard Roberts Jones of Aberdaron, in the county of Carnarvon, in North Wales, exhibiting a remarkable instance of a partial power and cultivation of intellect." This extraordinary character, who was originally a fisher-lad, "continues to display a love of learning and an extent of erudition seldom exhibited within the walls of schools or universities, united with a want of common sense amounting almost to idiocy, and a squalor and wretchedness of appearance of which a common mendicant would be ashamed." At Allerton he had a conversation with Dr Parr on languages, oriental and occidental; and on being afterwards asked his opinion of the learned stranger, he replied, "He is less ignorant than most men."

During this year he quitted his residence in Liverpool, and took a house in Lodge Lane, Toxteth Park, about a mile from the town. Two years afterwards he had the severe misfortune to lose the excellent and cherished partner of all his joys and sorrows. She died on the 24th of September 1824. This event was very deeply felt; but the affectionate attention of his two daughters afforded some compensation of a loss which it was impossible to repair. In the early part of the year he had been elected an honorary associate of the Royal Society of Literature; and after an interval of a few months he was appointed an associate of the first class. He thus became entitled to a pension of one hundred guineas; but, on the death of the king, the annual grant from the privy purse was withheld by his successor. As its total amount was only a thousand pounds, this cannot but be considered as a miserable piece of economy. In 1827 the great gold medal of the society was awarded to him for his merits as an historian. From other learned associations he obtained various honours; nor must we omit to state that, during the same year, he was elected a corresponding member of the Accademia della Crusca.

In the spring of 1821 he had been engaged by the London booksellers to undertake a new edition of the Works of Pope. It appeared in 1824, in ten volumes octavo. He contributed a copious and elegant life of the author, and to a selection of the notes of former editors added a few of his own. Of the character of Pope, both as a man and as a poet, he formed a more favourable estimate than either Dr Warton or Mr Bowles. Those who deny or reluctantly concede to Pope the name of a poet, seem to judge according to a very arbitrary standard. A few months after the appearance of this edition, Mr Bowles published "A final Appeal to the Literary Public, relative to Pope, in Reply to certain Observations of Mr Roscoe, in his Edition of that Poet's Works; to which are added, some Remarks on Lord Byron's Conversations, so far as they relate to the same subject and the Author: in Letters to a Literary Friend." To this publication Mr Roscoe speedily replied in "A Letter to the Rev. W. Lisle Bowles, A. M. Prebendary of Sarum, &c. in Reply to his 'Final Appeal to the Literary Public relative to Pope.'" His edition, as well as his Letter, obtained a favourable notice in the Quarterly Review for October 1825; and Mr Bowles was induced to publish "Lessons in Criticism to William Roscoe, Esq. F. R. S. &c. in Answer to his Letter to the Rev. W. L. Bowles, on the Character and Poetry of Pope. With further Lessons in Criticism to a Quarterly Reviewer." These lessons in criticism were not very satisfactory to the public, and Mr Roscoe wisely desisted from any further controversy.

In 1827 he published an edition of the Life of Lorenzo in two, and of the History of Leo in four volumes octavo. He had now reached an advanced period of life, and had begun to feel the pressure of age. Towards the close of this year, he was suddenly attacked with paralysis, which affected one side of his face, and deprived him of the use of one hand; but medical aid was promptly procured, and he recovered the use of his hand, as well as of his speech. Botany had been among the number of his favourite pursuits. He had been a contributor to the Transactions of the Linnæan Society, and was regarded as no mean proficient in this science. After his recovery from the paralytic attack, he published the fifteenth and concluding number of a splendid volume on Monandrian Plants. Towards the end of June 1831 he experienced a severe attack of influenza; and after he seemed to be recovering, he was on the 27th of that month seized with a violent fit of shivering, accompanied with almost total prostration of strength. The near approach of death he contemplated with calm resignation to the will of God. On the 30th he closed his mortal career, after having completed the seventy-eighth year of his age. The proximate cause of his death was an effusion into the chest. His remains were interred in the burying ground of the Unitarian chapel in Renshaw Street, the service being performed by his intimate friend Mr Shepherd. Six sons and two daughters survived him. One daughter he had lost in her infancy, and a son in his mature age. His eldest daughter was married to Thomas Jevons, Esq. of Liverpool. One of his sons, who still survives, is well known as a man of letters. Another has too speedily followed the father to the grave. He was a barrister at law; and, besides several works connected with his own profession, he published an interesting though somewhat diffuse account of his honoured father's life.[1]

Dr Traill, the friend and physician of this eminent man, speaks of him in the following terms. "In person, Mr Roscoe was tall and rather slender. In early life he possessed much bodily activity. His hair was light auburn, almost inclining to red; his full grey eye was clear and mild; his face expressive and cheerful. As he advanced in life, the benevolent expression of his countenance remained, but the vivacity of the features was tempered into a noble dignity, which it was impossible to see without respect and admiration; while the mouth bespoke taste and feeling, and the clustering hoary hair round his temples gave a venerable air to his manly features.... Of the qualities of his heart, as a private individual, it is impossible to speak too highly. In the relations of husband, father, and friend, his conduct was most exemplary; and it would be difficult to point out a man who possessed the fascination of manner which attracts and rivets attachment, in a higher degree than William Roscoe."[2]

ROSCOMMON, an inland county in the province of Connaught, in Ireland, is bounded on the north by the county of Sligo, on the east by those of Leitrim, Longford, and Westmeath, on the south-east by the King's County, on the south-west by Galway, and on the west by the same county and by Mayo. It extends over a surface of 609,405 acres, of which 453,555 are cultivated, 131,063 are uncultivated mountain or bog, and 24,787 are under water. According to Ptolemy, it was inhabited by the Auteri; afterwards the tribes or septs of the O'Conors, O'Kellys, M'Dermots, O'Flanegans, O'Flyns, and O'Hanlys, were the chief possessors of it. Shortly after the arrival of the English in the reign of Henry II. it was seized upon by the new settlers, and their maintenance of it secured by the erection of several fortresses. For a long period afterwards the whole province was considered as consisting but of two counties, that of Roscommon being one, and all the remainder, with the county of Clare included, the other, under the name of the county of Connaught. This arrangement continued until the beginning of the reign of Elizabeth, when the whole province underwent a new classification, and the county of Roscommon was divided into the baronies of Athlone, Ballintubber, Boyle, Moycarnon, and Roscommon. At the close of the war of 1641, nearly all the former proprietors were dispossessed for having espoused the royal cause, and their possessions transferred to the republican adventurers and soldiers; since which period, that branch of the O'Conor family, once sovereigns of all Ireland, now known by the name of the O'Conor Don, is the only one of the former possessors who holds any part of ancestral possessions in the country. The five baronies are subdivided into fifty-three parishes, and four parts of parishes, the remaining parts of which are in some of the adjoining counties. According to the ecclesiastical arrangements of the country, Roscommon contains fifty-seven parishes, of which fifty-one are in the diocese of Elphin, three in Tuam, two in Clonfert, and one in Ardagh. The seat of the bishopric of Elphin is in the town of the same name in the county.

Roscommon is in shape long and narrow, extending sixty miles in a northern and southern direction, whilst its breadth from east to west, where greatest, is but thirty-two miles; and it decreases gradually until it terminates in a point in its southern extremity. The greatest part of it is level, forming the western portion of the central flœtz limestone field of Ireland; varied, however, by frequent inconsiderable elevations, and by long low ridges or escars formed of limestone gravel. In the north the country rises into rugged mountains with abrupt precipitous sides and flattened summits, the highest of which, Bracklieve and Slieve Corkagh, are upwards of a thousand feet above the level of the sea. The equally wild though less elevated range of the Curlew Mountains also forms part of the northern boundary. The Slieve Bawn Mountains range along the middle part of the eastern boundary. Slieve Aluyn, in the west, is also of considerable height. No large river passes through the county, but both its eastern and western limits are watered by navigable streams. To the east the Shannon rolls its immense volume of waters along that whole side, and on the west the Suck, which is navigable for barges to Ballinasloe, unites with the Shannon at the extreme south point. The rivers in the interior, which are small and insignificant, are all tributaries to one or other of these main channels, and chiefly to the former, discharging themselves into their streams, either directly, or through the medium of some of the numerous lakes dispersed throughout various parts. Of these smaller rivers, the Arigna, the Fiorish, and the Gara or Boyle river, are tributaries to the Shannon; the Bresgue and the Lung, the latter of which flows through a subterraneous channel during part of its course, discharge their contents into Lough Gara. The most remarkable of the lakes, both for size and beauty, is Lough Kea in the northern part, near the town of Boyle, from which place it also takes a name, as likewise that of Rockingham Lake, from the seat of Lord Lorton upon its shore. It is about three miles in length by two in breadth, and studded with several picturesque islands, amongst which Trinity Island is noted for its monastic ruins, and Castle Island for an ancient fortress of the M'Dermots, now modernized into an elegant villa. The lake derives its supply from the neighbouring boundary lake of Lough Gara upon the borders of Sligo, which, though larger, and still more irregular in its outline, is less attractive in appearance than that on which it bestows its redundant waters. To the north of Lough Kea the two smaller lakes, Lough Skeen and Lough Meelagh, are connected by a short channel with the Shannon. The lakes of Bodarrig, Boffin, and Reagh, on its eastern side, which are, strictly speaking, expansions of the Shannon, may also be considered as partially belonging to the county. The principal of the smaller lakes are Loughs Errit, Glynn, Funcheon, and Aluyn. There are several extensive furloughs or winter lakes, which, being generally dry in summer, afford rich pasturage for sheep. Between Frenchpark and Elphin, that of Mantua covers seven hundred acres; another near Lough Glynn, in the extreme west of the county, is half a mile long.

---

[1] The Life of William Roscoe, by his son, Henry Roscoe. Lond. 1833, 2 vols. 8vo.

[2] Edinburgh New Philosophical Journal, vol. xiii. p. 220.

The limestone, which forms the base of all the level districts, is of various kinds, some gray, containing numerous fossil remains, chiefly madrepores; some of the formation called calp, which is often found blended with layers of Lydian stone; and some black, being susceptible of a high polish, as is a light gray marble found in the southern parts. Sandstone shows itself in the eminences that protrude through the limestone. Slieve Bawn is mostly composed of it; and in the neighbourhood of Frenchpark it is raised in laminæ so thin as to be used for the covering of roofs. The northern district is of the coal formation, which extends also into the adjoining county of Leitrim; but the principal stores of this most valuable mineral, and of ironstone, are to be found on the Roscommon side. The entire area, which is divided into two parts by the Arigna, extends over six thousand five hundred acres, of which two thousand are to the north and four thousand five hundred to the south of that river. The strata of coal rise into the mountains of Bracklieve and Slieve Corkagh, where the outcrop may be distinctly seen in several places in the precipitous sides of the declivities. The coal is of the blazing or bituminous character, less inflammable than that of Scotland, but more so than that of the north of England. The principal beds are the Rover, Gubberother, and Aughabehy collieries, in the latter of which, the chief seam, and the only one deemed sufficiently rich to defray the expense of working, is from one foot to two and a half feet thick, and promises to be abundant in quantity, although subject to interruptions, or what the workmen call faults, occasioned by the strata of one part of a hill having slipped down to a depth of from twenty to fifty yards, and settled on a lower level. The principal beds of iron ore are also on the south side of the Arigna river, whence the workings derive their name. They exhibit decisive indications of having been in operation at an early period; but, most probably in consequence of the exhaustion of timber for fuel, they were latterly inoperative until 1788, when the pit-coal found in the neighbourhood led to a new speculation in them, which, however, was dropped at the end of twenty years. The workings were resumed by three of the mining companies which the extravagant spirit of joint-stock enterprise gave rise to about the year 1825; but only one of them, the Arigna company, persevered in the experiment, until involved in a chancery suit as to the right of tenure, which being decided against them in 1836, the works have been resumed by their successful opponent, by whom they are now carried on upon a very extended scale, and with a prospect of adequate remuneration for the capital sunk in the concern. Both the ironstone and the limestone used as a flux have been pronounced to be of prime quality. Potters' clay is found in several places, and is manufactured into the coarser kinds of wares. Fire-bricks are made at Arigna, of fire-clay, which forms some of the mineral strata there.

The soil varies nearly according to the nature of its substratum, that on the limestone being much the most productive; except in the hilly district between the Shannon and the Suck, in which the stone rises so near the surface that the superincumbent vegetable mould is scarcely of depth sufficient to admit the use of the plough. The borders of the rivers which flow through the level parts, and are therefore liable to overflow their banks during winter, become, on the return of dry weather, pastures and meadows of the richest quality. Bogs of every size, from an extent of a thousand acres to patches merely adequate for the domestic demands of the immediate neighbourhood in which they lie, are to be found in many parts. The mountains are mostly covered with bog and marsh, interspersed with dry patches on which heath grows most luxuriantly. In the southern part, large tracts of a very light sandy soil, lying on the low hills between the Suck and the Shannon, afford excellent pasturage for sheep. The borders of Lough Aluyn are in some parts formed of sand, apparently carried from the lake by the wind. Large deposits of gravel and different kinds of loam are often found between the surface-soil and the rock which forms the substratum.

The population, according to calculations made at different periods, was as follows:

Year.	Authority.	Population.
1760	De Burgo	41,172
1792	Beaufort	86,000
1812	Parliamentary Return	158,111
1821	Ditto	208,729
1831	Ditto	239,903

The latest of these returns gives a ratio of one inhabitant to every 2·54 acres, or of one to every 1·89 cultivated acre. The returns of the Commissioners of Public Instruction in 1834 having been made up according to dioceses, though they do not give results sufficiently accurate to be placed along with those in the preceding table, afford data sufficient respecting the comparative numbers of the three principal religious persuasions, to justify the statement, that if the whole population of the county be estimated at 240,000 (a close approximation to that of 1831), the numbers of Protestants are 7000, and of Roman Catholics 233,000, being an average of one to thirty-three nearly. The total number of protestant dissenters in the county, according to the same return, was but forty-three.

This population was represented in the Irish parliament by eight members; two for the county at large, and two for each of the boroughs of Boyle, Roscommon, and Tulsk. The number was reduced to two at the Union, all the boroughs being deprived of the right of election. The number of registered electors for the county is about two thousand; elections are held at Roscommon. The local government is vested in a lieutenant, ten deputy-lieutenants, all appointed by the crown during pleasure, and a hundred magistrates, in which number the lieutenant and his deputies are included, appointed by the lord chancellor, and continued during good behaviour. The constabulary force consists of a sub-inspector, six chief constables, seven head constables, forty-three constables, and a hundred and eighty-seven sub-constables; total two hundred and forty-four.

The state of education, according to the parliamentary returns made in 1821 and 1824–26, was as follows:

Year.	Boys.	Girls.	Sex not ascertained.	Total.
1821	6981	3306	—	10,287
1824–26	8937	4998	711	14,646

Of the numbers stated in the latter of these returns, 1041 were Episcopalian Protestants, and 13,262 Roman Catholics; the religious persuasion of the remaining 343 was not specified. The total number of schools in the county was 309; of which seventeen, containing 545 pupils, were maintained by grants of public money; thirty-eight, containing 1954 pupils, by the voluntary contributions of societies or individuals; and the remaining 254 schools, which afforded the means of instruction to 12,147 pupils, were maintained wholly by the pupils' fees. The report of the Commissioners of National Education in 1837 (the latest published) states the number of schools, teachers, and pupils, connected with their board, as follows: Schools, eleven; teachers, twelve; boys, 941; girls, 757; total of pupils, 1698. The diocesan school of the see of Elphin is in the county.

The habits of the population are so thoroughly rural, that there are but four towns of which the population of each exceeds a thousand souls, two of them containing between three and four thousand, and the other two between one and two thousand. There are several fine mansions and demesnes in the hands of resident noblemen and gentlemen, and numerous villas and country-seats belonging to independent landed proprietors; but as to the small farmers and cottiers, the appearance of their dwellings and homesteads in many cases are far from showing those indications of internal comfort that might be expected in a district so highly favoured by nature. Agriculture is carried on with much spirit amongst the higher classes, by whom the latest improvements in tillage, and the best constructed vehicles and implements, have been introduced; but the old customs and antiquated implements are pertinaciously adhered to by most of the smaller farmers. Wheat is largely sown; a judicious rotation system is carried on; and green crops are frequent, with the exception of turnips and mangel-wurzel, which have not been found to answer. In the mountainous districts the spade is frequently used instead of the plough. In these also the neighbouring landholders generally club their labour together, particularly in planting and raising potatoes, all uniting to complete the work of one farm, and then proceeding successively in a body to execute that of the other partners in the amicable joint-stock concern. The pastures are amongst the best in Ireland, and as their proprietors are almost fastidiously particular in the selection of live stock of every description, the best-fed beasts are to be met with here. This is peculiarly the case with respect to bullocks; the sheep also are of first-rate quality, both as to fleece and flavour of carcass. In prime grazing land an acre feeds a bullock and a sheep. Notwithstanding the superior capabilities of the soil for pasturage, there are not many large dairies. But few farms, however small, are without one cow, if not more, so that butter of excellent quality is made, not only sufficient for the internal demand, but for forming a material article of export. The breed of horses is much esteemed. The annual fair of Ballinasloe, in October, is the principal mart at which the black cattle and sheep are disposed of. Fences in general are made of stone-walls, raised to a considerable height, as they are considered to afford better shelter for cattle than those of timber. That the county was once well wooded, appears not only from the evidence of history, but from the fact that wherever the impediments to its growth are removed, the soil spontaneously throws up shoots of those species of forest-trees with which the whole face of the country was once covered. The excessive clearing of the woods, without precautionary measures to secure a new growth, has left the surface very bare; but this defect, equally unsightly to the eye of taste and injurious to the progress of improvement, is annually diminishing, through the exertions of the landed gentry, many of whose mansions are surrounded with noble plantations. Manufactures, with the exception of those already noticed, and of coarse woollens and linens for domestic consumption, are almost unknown. The articles of export are confined to agricultural produce and live stock, for which the recent improvements on the course of the Shannon have afforded great facilities. The navigation of this fine river, which, as has already been said, skirts the county along the whole of its eastern verge, was so much obstructed by several rapids as to render it useless as a channel of enlarged inland traffic. These impediments have been obviated by means of short canals along the side of the river in those parts where the rapids occur. The first is from Lough Allen in Leitrim to Battlebridge, whence the river-stream is available somewhat farther than Carrick, where a second canal serves to avoid the rapids between Jamestown and Drumsna. Other short canals occur at the falls of Ruskey, of Lanesborough, and of Athlone. Thence the channel is clear to the junction with the Suck, where it quits the county. The connection by water with the eastern counties to Dublin is maintained by the Royal and Grand Canals, which communicate with the Shannon at Tarmonbarry and Shannon Harbour. The principal exports are corn and butter, all the coal as yet raised being not more than sufficient for the supply of the districts surrounding the collieries. As all the great lines of land conveyance to Connaught from Leinster and Ulster pass through the county, the roads are numerous, and generally well kept up.

The monastic antiquities are very numerous. The ruins of the abbey of Boyle still exhibit a large part of its highly ornamented church, with its tower rising from the middle of the building, and resting on four columns of colossal dimensions, enriched with a variety of sculptures; and the Dominican friary at Roscommon contains a monument of an ancient member of the O'Conor family, exhibiting an effigy of an armed warrior in a lying posture, with four other armed figures on the base. Derhan Abbey, in the neighbourhood of Roscommon, is little more than a heap of stones. The others of which some relics still exist, are Trinity Abbey in Lough Kea, Tulsk, Clonshanvill, and Clontuskert, in which there are several monuments and inscriptions relating to the O'Kellys and other ancient families. In the parish of Oran on the Suck, in the west of the county, are the remains of an ancient pillar-tower, about ten feet high; and in every part there are raths so numerous that nearly five hundred are still visible. The county contained a great number of small fortresses, evidently built when it was one of the marches or border districts, to repress the incursions of the Connaught Irish, besides which there were a few of great extent and strength, as is testified by that of Roscommon, forming a quadrangle of 220 by 180 feet, with towers at the angles and at the gateway, and containing the remains of a large building, supposed to be the residence of the governor. The most remarkable of the other castles are those of Athlone, Ballinasloe, Ballynafad, and Lough Glynn.

Roscommon, the county town, is built on the sides of a hill, near the middle of the county, in a plain between the Shannon and the Suck. It consists but of one main street, with several minor avenues branching out into five main roads, in various directions. It was incorporated at a very early period, and was considered to be one of the chief places in these parts. Writs for the better defence of the town and castle are frequent among the earlier records. It returned two members to the Irish parliament till the Union. Here are all the buildings connected with the local administration of justice. The county court-house is a spacious and well-arranged edifice, with an elegant Grecian-Doric portico in front. The county prison, built on the radiating plan, contains accommodations for upwards of a hundred prisoners, and has a tread-mill. The county infirmary, which also contains a fever hospital and infirmary, admits an average of three hundred patients annually. The modern ecclesiastical buildings are not remarkable for architectural elegance. The parish church is a neat structure. The old court-house has been converted into a Roman Catholic chapel. The town is a place of very limited trade, except in that of grain, large quantities of which are sent to Lanesborough to be exported thence by means of the Royal Canal or the Shannon. The population in 1831 was 3306. That of other towns the number of whose inhabitants exceeded 1000, was Boyle, the largest and most commercial in the county, 3433; Strokestoun, 1548; and Elphin, in which there is a poor cathedral to a very wealthy diocese, and a diocesan school, 1507. That part of the town of Athlone on the Shannon, in which the fortified magazines and works intended for the defence of the pass of the Shannon have been built, is on the Roscommon side of the river. The greater part of the town of Ballinasloe, celebrated for its great annual fair of sheep and horned cattle, is also in this county.

Roscommon, *Wentworth Dillon, Earl of*, a celebrated poet of the seventeenth century, was the son of James Dillon, earl of Roscommon, and was born in Ireland, under the administration of the first Earl of Strafford, who was his uncle, and from whom he received the name of *Wentworth* at his baptism. He passed his infancy in Ireland; after which the Earl of Strafford sent for him into England, and placed him at his own seat in Yorkshire, under the tuition of Dr Hall, afterwards bishop of Norwich, who instructed him in Latin, without teaching him the common rules of grammar, which he could never retain in his memory, though he learned to write in that language with classical elegance and propriety. On the Earl of Strafford's being impeached, he went to complete his education at Caen in Normandy; and after some years he travelled to Rome, where he became acquainted with the most valuable remains of antiquity, and in particular was well skilled in medals, and learned to speak Italian with such grace and fluency that he was frequently taken for a native. He returned to England soon after the Restoration, and was made captain of the band of pensioners; but a dispute with the lord privy-seal about a part of his estate obliged him to resign his post, and revisit his native country, where the Duke of Ormond appointed him captain of the guards. He was unhappily very fond of gaming; and as he was returning to his lodgings from a gaming-table in Dublin, he was attacked in the dark by three ruffians, who were employed to assassinate him. The earl defended himself with such resolution, that he had despatched one of the aggressors, when a gentleman passing that way took his part, and disarmed another, on which the third sought his safety in flight. This generous assistant was a disbanded officer of good family and fair reputation, but reduced to poverty; and his lordship rewarded his bravery by resigning to him his post of captain of the guards. He at length returned to London, when he was made master of the horse to the Duchess of York, and married the Lady Frances, the eldest daughter of Richard earl of Burlington, and the widow of Colonel Courtney. Here he distinguished himself by his writings; and, in imitation of those learned and polite assemblies with which he had been acquainted abroad, he began to form a society for refining and fixing the standard of the English language, in which his great friend Dryden was a principal assistant. This scheme, however, was entirely defeated by the religious commotions which ensued on King James's accession to the throne. In 1683 he was seized with the gout; and being too impatient of pain, he permitted a bold French empiric to apply a repelling medicine, in order to give him immediate relief. This drove the distemper into his bowels, and in a short time put a period to his life. He died in the month of January 1684, and was buried with great pomp in Westminster Abbey.

His poems, which are not numerous, are in the body of English poetry collected by Dr Johnson. His Essay on Translated Verse, and his translation of Horace's Art of Poetry, have been much commended. Upon the latter, Waller addressed a poem to his lordship when he was seventy-five years of age. "In the writings of this nobleman we view," says Fenton, "the image of a mind naturally serious and solid; richly furnished and adorned with all the ornaments of art and science; and these ornaments unaffectedly disposed in the most regular and elegant order. His imagination might probably have been more fruitful and sprightly, if his judgment had been less severe; but that severity (delivered in a masculine, clear, succinct style) contributed to make him so eminent in the didactical manner, that no man with justice can affirm he was equalled by any of our nation, without confessing at the same time that he is inferior to none. In some other kinds of writing his genius seems to have wanted fire to attain the point of perfection; but who can attain it?" He was a man of an amiable disposition, as well as a good poet; as Pope, in his Essay on Criticism, has testified in the following lines:

> Roscommon not more learned than good,
> With manners generous as his noble blood;
> To him the wit of Greece and Rome was known,
> And every author's merit but his own.

We must allow of Roscommon, what Fenton has not mentioned so distinctly as he ought, and what is yet very much to his honour, that he is perhaps the only correct writer in verse before Addison; and that, if there are not so many or so great beauties in his composition as in those of some contemporaries, there are at least fewer faults. Nor is this his highest praise. For Pope has celebrated him as the only moral writer of King Charles's reign.

> Unhappy Dryden! in all Charles's days,
> Roscommon only boasts unspotted lays.

"Of Roscommon's works," as Dr Johnson has remarked, "the judgment of the public seems to be right. He is elegant, but not great; he never labours after exquisite beauties, and he seldom falls into gross faults. His versification is smooth, but rarely vigorous; and his rhymes are remarkably exact. He improved taste, if he did not enlarge knowledge, and may be numbered among the benefactors to English literature.

ROSE. See Rosa.

Rose of Jericho, so called because it grows in the plain of Jericho, though it did not originally flourish there. It has perhaps been so named by travellers who did not know that it was brought from Arabia Petræa. Rose-bushes are frequently found in the fields about Jericho; but they are of a species much inferior to those so much extolled in Scripture, the flowers of which some naturalists pretend to have in their cabinets.

Roses, *Ottar* or *Essential Oil of*, is obtained from roses by simple distillation. A quantity of fresh roses, for example forty pounds, is put in a still with sixty pounds of water, the roses being left as they are with their calyxes, but with the stems cut close. The mass is then well mixed together with the hands, and a gentle fire is made under the still; when the water begins to grow hot, and fumes to rise, the cap of the still is put on, and the pipe fixed; the chinks are then well luted with paste, and cold water put on the refrigeratory at top. The receiver is also adapted at the end of the pipe; and the fire is continued under the still, neither too violent nor too weak. When the impregnated water begins to come over, and the still is very hot, the fire is lessened by gentle degrees, and the distillation continued till thirty pounds of water are come over, which is generally done in about four or five hours. This rose-water is to be poured again on a fresh quantity (forty pounds) of roses, and from fifteen to twenty pounds of water are to be drawn by distillation, following the same process as before. The rose-water thus made will be found, if the roses be good and fresh, and the distillation carefully performed, highly scented with the roses. It is then poured into pans either of earthen ware or of tinned metal, and left exposed for the night to the fresh air. The ottar or essence will be found in the morning congealed, and swimming on the top of the water; and this is to be carefully separated and collected either with a thin shell or a skimmer, and poured into a phial. When a certain quantity has thus been obtained, the water and feces must be separated from the clear essence; which, with respect to the first, will not be difficult to do, as the essence congeals with a slight cold, and the water may then be made to run off. If, after that, the essence is kept fluid by heat, the feces will subside, and may be separated; but if the operation has been neatly performed, these will be little or none. The feces are as highly perfumed as the essence, and must be kept, after as much as possible of the essence has been skimmed from the rose-water. The remaining water should be used for fresh distillations, instead of common water, at least as far as it will go.

The above is the whole process, as given in the Asiatic Researches (vol. i. p. 332), of making genuine ottar of roses. Attempts, as the writer states, are often made to augment the quantity, though at the expense of the quality. Thus the raspings of sandal-wood, which contain a deal of essential oil, are used; but the imposition is easily discovered, both by the smell, and because the essential oil of sandal-wood will not congeal in common cold. In other places they adulterate the ottar by distilling with the roses a sweet-scented grass, which colours it of a high clear green. This does not congeal in a slight cold. There are numerous other modes, far more palpable, of adulteration. The quantity of esential oil to be obtained from roses is very precarious, depending on the skill of the distiller, on the quality of the roses, and on the favourableness of the season. The colour of the ottar is no criterion of its goodness, quality, or country. The calyxes by no means diminish the quality of ottar, nor do they impart any green colour to it. They indeed augment the quantity, but the trouble necessary to strip them is such as to prevent their being often used.

The following is a simpler and less expensive process for preparing this delicate and highly valued perfume, but whether it be equally productive we know not. A large earthen or stone jar, or a large clean wooden cask, is filled with the leaves of the flowers of roses, well picked and freed from the seeds and stalks; and as much spring-water as will cover them being poured into the vessel, it is set in the sun in the morning at sunrise, and allowed to stand till the evening, when it is removed into the house for the night. In the same way it is to be exposed for six or seven days successively. At the end of the third or fourth day a number of particles of a fine yellow oily matter is seen floating on the surface; and these particles in the course of two or three days more collect into a scum, which is the ottar of roses. This is taken up by means of cotton tied to the end of a piece of stick, and squeezed with the finger and thumb into a small phial, which is immediately well stopped; and this is repeated for some successive evenings, or whilst any of this fine essential oil rises to the surface of the water.

ROSEHEARTY, a burgh of barony in the county of Aberdeen, situated on the shores of the Moray Frith, and eighteen miles from Banff. The inhabitants, who amount to about 800, are mostly employed in fishing. It possesses a harbour, which may eventually become of importance, situated as it is on an exposed part of the coast, with a considerable depth of water. Its revenues amount to about L.100 yearly.

ROSENAU, a city of the Austrian kingdom of Hungary, in the province of the Hither Theiss, and circle of Gomör. It is situated on the river Sajo, and is the seat of a bishop, and of an episcopal seminary. It contains several churches, 680 houses, and 5400 inhabitants, trading in linen, paper, woodware, and ironmongery, and also producing good wine. Long. 20. 27. 13. E. Lat. 48. 39. 2. N.

ROSENGYN, one of the Banda Isles, about seven miles south-east of Lantore. Convicts were sent here when the island was in possession of the Dutch. The productions are nutmegs, mace, and yams; and here a few cattle are also fed.

ROSETO, a small city of Italy, of the province of Principato Ulteriore, and of the kingdom of Naples. It was long celebrated from possessing in its church an image of the Virgin Mary, brought there, according to a legend, in a miraculous manner, which induced many pilgrims from all parts of Europe to resort to it for purposes of devotion, and to present very valuable offerings. It was taken and plundered by the French, and the venerated image having been obtained by a private individual, has been restored to its former place; but the number of votaries has much diminished. The inhabitants amount to about 3000, who subsist principally in making holy trinkets, and from supplying lodging and provisions to the pilgrims who still resort to it.

ROSETTA, a town of Africa, in Egypt, is pleasantly situated on the west side of that branch of the Nile called by the ancients *Bolbitinum*, affirmed by Herodotus to have been formed by art; the town and castle being on the right hand as you enter the river. Any one who sees the hills about Rosetta would judge that they had been the ancient barriers of the sea, and conclude that the sea has not lost more ground than the space between the hills and the water.

Rosetta is esteemed one of the most pleasant places in Egypt. It is about two miles in length, and consists only of two or three streets. The country about it is most delightful and fertile, as is the whole Delta on the other side of the Nile, exhibiting the most pleasant prospect of gardens, orchards, and corn-fields, excellently cultivated. This place is also famous for having produced the celebrated monument which, interpreted by Dr Young, led to the discovery of hieroglyphical literature, and threw new light on a subject of great antiquity. It consists of a black basalt, fragmented, which the French troops had found when digging the foundation of Fort St Julian; and is inscribed, as far as it is entire, with the hieroglyphic or sacred, the demotic or enchorial, and the Hellenic or Greek character.

In the country to the north of Rosetta are delightful gardens, full of orange, lemon, and citron trees, and almost all sorts of fruits, with a variety of groves of palm-trees; and when the fields are green with rice, it adds greatly to the beauty of the country. It is about twenty-five miles north-east of Alexandria, and a hundred north-west of Cairo. Long. 30. 45. E. Lat. 31. 30. N.

ROSICRUCIANS, the name of a sect of philosophers, called hermetical philosophers, who arose, as it has been said, or at least became first conspicuous, in Germany, in the beginning of the fourteenth century. They bound themselves together by a solemn secret, which they all swore inviolably to preserve; and obliged themselves, at their admission into the order, to a strict observance of certain established rules. They pretended to know all sciences, and chiefly medicine, of which they professed themselves

Rosicrucians.

the restorers. They pretended to be masters of important secrets, and, amongst others, that of the philosopher's stone; all which they affirmed to have received by tradition from the ancient Egyptians, Chaldæans, the Magi, and Gymnosophists. They have been distinguished by several names, accommodated to the several branches of their doctrine. Because they pretended to protract the period of human life, by means of certain nostrums, and even to restore youth, they were called *Immortales;* as they pretended to know all things, they have been called *Illuminati;* and because they have made no appearance for several years, unless the sect of Illuminated which lately started up on the Continent derives its origin from them, they have been called the *Invisible Brothers.* Their society is frequently signed by the letters F. R. C. which by some amongst them are interpreted *Fratres Roris Cocti;* it being pretended, that the matter of the philosopher's stone is dew concocted or exalted. Some, who are no friends to free-masonry, make the present flourishing society of free-masons a branch of Rosicrucians, or rather the Rosicrucians themselves under a new name or relation, namely, as retainers to building.

Notwithstanding the pretended antiquity of the Rosicrucians, it is probable that the alchemists, Paracelsists, or fire-philosophers, who spread themselves through almost all Europe about the close of the sixteenth century, assumed about this period the obscure and ambiguous title of Rosicrucian brethren, which commanded at first some degree of respect, as it seemed to be borrowed from the arms of Luther, which were a cross placed upon a rose. But the denomination evidently appears to be derived from the science of chemistry. It is not compounded, as many imagine, of the two words *rosa* and *crux,* which signify rose and cross, but of the latter of these words, and the Latin *ros,* which signifies dew. Of all natural bodies, dew was deemed the most powerful dissolvent of gold; and the cross, in the chemical language, is equivalent to light, because the figure of a cross exhibits, at the same time, the three letters of which the word *lux,* or light, is compounded. Now *lux* is called, by this sect, the seed or menstruum of the red dragon, or, in other words, that gross and corporeal light, which, when properly digested and modified, produces gold. Hence it follows, if this etymology be admitted, that a Rosicrucian philosopher is one who, by the intervention and assistance of the dew, seeks for light, or, in other words, the substance called the philosopher's stone. The true meaning and energy of this denomination did not escape the penetration and sagacity of Gassendi, as appears by his *Examen Philosophiæ Fluddanæ,* sect. 15, tom. iii. p. 261; and it was more fully explained by Renaudot, in his *Conferences Publiques,* tom. iv. p. 87.

At the head of these fanatics were Robert Fludd, an English physician, Jacob Böhm, and Michael Mayer. The common principles which serve as a kind of centre of union to the Rosicrucian society are the following. They all maintain that the dissolution of bodies by the power of fire is the only way by which men can arrive at true wisdom, and come to discern the first principles of things. They all acknowledge a certain analogy and harmony between the powers of nature and the doctrines of religion; and believe that the Deity governs the kingdom of grace by the same laws with which he rules the kingdom of nature, and hence they are led to use chemical denominations to express the truths of religion. They all hold that there is a sort of divine energy, or soul, diffused through the frame of the universe, which some call the *archeus,* others the *universal spirit,* and which others mention under different appellations. They all talk in the most superstitious manner of what they call the signatures of things, of the power of the stars over all corporeal beings, and their particular influence upon the human race, of the efficacy of magic, and the various ranks and orders of demons. These demons they divide into two orders, *sylphs* and *gnomes;* which supplied the beautiful machinery of Pope's Rape of the Lock. In fine, the Rosicrucians and all their fanatical descendants agree in proposing the most crude and incomprehensible notions and ideas, in the most obscure, quaint, and unusual expressions.

ROSLIN, or Rosslyn, a village in the county of Mid-Lothian, Scotland, about seven miles south from Edinburgh, celebrated for the picturesque ruins of its castle, the architectural grace of its chapel, and the sequestered but variegated scenery of the vale in which they are placed. Roslin was formerly a place of some note, being next to Edinburgh and Haddington in importance, and was made a burgh of barony by James II. of Scotland, and privileged by holding fairs and markets. The sole dependence of the inhabitants at the present time is on agriculture and the bleaching of linen. The castle is situated on a peninsular rock, round which the South Esk river pursues its course; and is connected with the adjacent ground by an old narrow bridge thrown over a deep cut chasm in the solid rock. The original castle was most likely erected in the eleventh century. It must have been increased from time to time in after years, as we learn that when the Earls of St Clair were in their glory, the castle was not only a massive and extensive building, but characterized by great splendour in its internal decorations. All that now remain are some high fragments of the walls and battlements, and a triple tier of vaults. Amidst the ruins, and partly above these vaults, was built a more modern house, bearing the date of 1622, which is still inhabited.

The chapel was founded in the year 1446, by William St Clair, prince of Orkney and lord of Rosslyn, for a provost, six prebendaries, and two choristers, and consecrated to St Matthew. Tradition states that the design of the building, which was intended for a large collegiate church, was drawn at Rome; and that the prince employed the best workmen that could be procured, both from the Continent and at home, in the erection. The chapel, which is merely the chancel and part of the transept of the original design, is unique in style, and cannot be said to belong to any order of architecture. It however combines the solidity of the Norman with the elegance and minute profusion of ornament characteristic of the latest species of the Tudor age. The interior is sixty-eight feet in length, thirty-four feet in breadth, and forty feet in height. It is divided into a centre and aisles, by two ranges of clustered pillars, eight feet in height, adorned with sculptured foliage and figures of human beings and animals, of the most exquisite workmanship. The pillars are so arranged that their ceilings are thrown into one, so as to form a continued arch along the centre of the building. One pillar, conspicuous for its elaborate decorations, is called the "prentice pillar," from its having been sculptured by an apprentice, who is said to have lost his life from having thus excited the professional jealousy of his master. At the reformation in 1688 this chapel was, like many other sacred edifices of taste, defaced by a mob from Edinburgh; but it was repaired in the following century by General St Clair. The present Earl of Rosslyn is judiciously, and with great taste, restoring this venerable structure to its original state. Beneath this chapel lie the barons of Roslin, all of whom were, till the time of James VII., buried in armour. Near this was fought, in February 1302, the three celebrated battles of Roslin, where the Scots, under the regent Sir John Comyn, and Sir Simon Frazer, attacked and defeated three divisions of the English army.

ROSS, a market-town of the county of Hereford, in the hundred of Greytree, 115 miles from London. It is finely situated on a hill rising from the river Wye. Its chief trade is in the sale of cider. Pope has immortalized the place by his laudatory description of one of its residents, John

Kyrle, who died in 1724, having spent his income on works of utility and of beneficence. The market is held on Thursday. The population amounted in 1801 to 2347, in 1811 to 2261, in 1821 to 2962, and in 1831 to 3078.

Ross, or Ross Carbery, a town in the county of Cork, Munster, Ireland, is situated on an eminence, at the head of a narrow creek in Ross Bay. It is a place of great antiquity. The town is laid out on a regular plan, and consists of a square, from the four corners of which diverge so many streets. It has an ancient cathedral, embosomed in trees, which, with the wooded banks of the bay, forms a remarkably beautiful feature in the appearance of the town. The harbour is spacious, but of little use, in consequence of being blocked up by the sand. The population amounted in 1831 to 1522.

Ross, *New*. See New Ross.

ROSSIANO, a city of Italy, in the province of Calabria Citeriore, and the kingdom of Naples. It stands on the sea-shore, between the rivers Lucena and Celano. It is the see of a bishop, and has a cathedral, and twenty-three other churches, of which nine belong to the same number of monasteries or nunneries. The inhabitants amount to 7700.

ROSS-SHIRE, a county of Scotland, having that of Cromarty so curiously intermixed with it, that the description of both under one head is a matter not only of convenience, but of necessity. Ross-shire, comprising the districts of Ardross, Easter Ross, Ardmeanach or the Black Isle, Kintail, Strathcarron, and the island of Lewis, is the most extensive county in Scotland, and second only to Yorkshire as regards Great Britain. The county of Cromarty, on the other hand, is comparatively small. It is divided into ten portions, which are whimsically inserted into various parts of the larger county of Ross, like fragments of a more ancient rock in some newer geological formation. One of these parts is the original county of Cromarty, so called from *Cromba*, that is, crooked bay, from the windings of its shores, consisting of that portion which lies in the peninsula to the south of the Cromarty Frith, and which surrounds the county town. This part rises like a huge lump to a height of 470 feet above the level of the sea, which washes the base of its cliffs. As a county, it was very inconsiderable both in extent and in value. But by the straggling additions which were made to it towards the end of the seventeenth century, it was increased to fifteen times its former extent. Of these additions, one is that district surrounding Tarbat House, on the northern shore of Cromarty Bay; and a second runs from the south side of Dornoch Frith to Moray Frith, cutting off that portion of the county of Ross which terminates in Tarbat Ness. Two more fragments are found lying on the north of the river Carron, which has its embouchure near Bonnar Bridge; a fifth is that which runs northward from the burgh of Dingwall, taking in Castle Leod and part of Ben Weavish; the sixth lies to the north of Loch Fannich, at some distance to the north-west of which a triangular morsel is found to the north of Loch Nid; the eighth is that which stretches along the southern shore of Little Loch Broom; and the ninth is the large district of Coygach, lying between the northern shore of Loch Broom and Sutherlandshire; to which may be added the Summer Islands at the mouth of Loch Broom, which are about sixty miles distant from the town of Cromarty. As we have already mentioned under the article Cromarty, this strange arrangement of territory was produced by the influence of that great and powerful proprietor, George viscount Tarbat, afterwards earl of Cromarty, who, wishing to have all his various lands included in one shire, got them annexed to his own county in 1685 and 1698. But these were not all, nor the most extraordinary, annexations which he accomplished. For, as a part of the county of Cromarty, we are compelled to notice Royston, or Caroline Park, locally situated within the county of Edinburgh, and but a couple of miles from the Scottish capital. But such arrangements were by no means singular. The district of Ferintosh, belonging locally to Ross-shire, is in fact a part of Nairnshire; and from similar causes many of the houses in the Canongate of Edinburgh belong to different counties in Scotland, from their having been the town residences of Scottish noblemen whose estates lay in those different shires. By the addition of all those portions which we have enumerated, the extent of Cromarty is calculated to be equal to an area of 345 square miles, or about 220,800 imperial acres. It contains only one entire parish, that of Cromarty, the other parts of it being parochially connected with parishes belonging to Ross-shire. The two towns of Cromarty and Ullapool belong to it, and its whole population may be estimated at about 5000 or 6000 souls. It is judicially under the jurisdiction of the sheriff of Ross, the sheriff-court being held at Cromarty every alternate Friday; and it is politically united with Ross-shire in returning a member to parliament. It contains about 20,000 arable acres. It has a considerable trade in pork for the English market; and at Cromarty there is a thriving manufactory of hempen cloth, which employs about two hundred individuals.

Having thus given a general notion of the county of Cromarty as distinct from that of Ross, we may now proceed to consider the united counties under one view. Ross has its name from *Ross*, a promontory, and probably from that of Tarbat Ness. The united shires lie between 57. 8. and 58. 10. north latitude, and between 4. 0. and 5. 46. west longitude from Greenwich. From the extreme northern point of Coygach, to the southern extremity of the Ross-shire boundary, which lies to the north-east of Loch Hourn, in Inverness-shire, the distance may be about seventy-two miles; whilst from Strath Oikel to the Cowrie Water the measurement is not more than thirty or thirty-five miles. The breadth from Tarbat Ness to the extreme western coast to the north of Gairloch is about eighty-five miles. The whole surface may be about 2424 square miles, or about 1,545,600 acres; but to this must be added the Lewis, which contains four of the thirty-three parishes of which the united county of Ross and Cromarty consists. The boundaries are Sutherlandshire and Dornoch Frith on the north, and Moray Frith on the east, Inverness-shire on the south, and the Western Ocean on the west. On the eastern coast Cromarty Frith shoots inland from that of Moray through the narrow strait produced by those grand and picturesque headlands called the Sutors of Cromarty, and expands into a still and land-locked basin, capable of holding the whole navy of Great Britain. The headlands themselves are so lofty and precipitous, that it is not uncommon during gales of wind from the north-eastward, to see waves breaking upon them to the height of an hundred feet, whilst all within is smooth. Stowe, in his Chronicle, calls it "an exceeding quiet and saue hauen;" Boyce calls it "the hail of seamen;" and Buchanan is still more particular in his praise of it. It is rather more than five miles broad at the widest part, and its length is about eighteen. The depth averages from nine to twelve fathoms, but in the entrance it in some places exceeds thirty, a depth which nearly doubles that of Moray Frith, into which it opens. The continuity of outline of the western coast is interrupted by many bays and sea-lochs, which afford numerous havens of shelter. From south to north, these are Loch Alsh, with its two branches Loch Duich and Loch Ling; Loch Carron, with its branch Loch Keeshorn; Loch Torridon, Gairloch, Loch Ewe, Loch Greinord, Little Loch Broom, Loch Broom, and Loch Enard. All these exhibit magnificent scenery. That of Loch Torridon, for example, is of the grandest and wildest character; as is likewise that of Loch Duich, rendered peculiarly interesting by the remains of the Castle of Eilean Donnan, the ancient stronghold of the Mackenzies, the Lords of Kintail. The outer headlands of the western coast of Ross-shire, north of Loch Carron, are composed of sandstone, exhibiting the usual smooth and regular outline characteristic of that formation; and hence the promontories are tame, and of an unvaried reddish coloured aspect, and the shores of the bays are for the most part covered over with brown heath. It is therefore more in the inner recesses of these inlets, and perhaps somewhat inland, that truly beautiful and romantic scenery is to be found. The coast of the island of Lewis is so indented with bays, lochs, creeks, and long and tortuous arms of the sea, as to bid defiance to any enumeration or description within the confined limits assigned to this article.

The general surface of Ross and Cromarty is wild and mountainous, the mountain chains and groups being interspersed with valleys, glens, lakes, and rivers, exhibiting nature in every variety of form and character. The mountains, and particularly those towards the west, are covered with excellent pasture for sheep. Some of the sheep-farms are extensive, and possessed by sheep-farmers of capital, who have introduced the Cheviot breed of sheep, or a cross of that breed. The valleys and glens are depastured by large herds of cattle. Although agriculture is found in patches in the valleys and on the shores of the west coast, the great agricultural district of Ross and Cromarty is that extending from Dingwall along the northern shore of Cromarty Frith, and so onwards in a north-eastern direction along the Moray Frith and that of Dornoch. The soil and climate of Easter Ross are as fine as any in Scotland, the agriculture is of the very best description, and the numerous gentlemen's seats and extensive plantations with which it is ornamented render this one of the most pleasant, smiling, and cheerful countries that the stranger can visit. All the grains and other agricultural produce of Britain are here raised in perfection; and if we were desired to fix on a spot in any part of Scotland where the best fruits could be produced, or where the rarest or most delicate plants or trees could best be reared, we should be disposed to fix on Tarbat House, on the northern shore of the Bay of Cromarty. We may further venture to assert, that no traveller of taste can possibly drive along that northern shore, from Dingwall eastwards, without very great enjoyment. The roads made in Ross-shire by the parliamentary commissioners are extensive and excellent, and they are kept in the highest state of repair. Many of the wildest and most unapproachable districts have thus been opened; but there are still many left hermetically sealed against all but the adventurous horseman or the unwearied pedestrian.

Amongst the numerous fresh-water lakes and rivers to be found in Ross and Cromarty, we may particularize the following. On the eastern side of the island we have Loch Ailsh and Loch Craggan, that give birth to the river Oikel, which divides Ross-shire from Sutherland, and which, after a course of forty miles, finds its way into the upper end of Dornoch Frith, near the fine iron-arched bridge of Bonnar. Then, as we move southwards, we have the river Carron and the Water of Fearn, discharging themselves into the same frith. Cromarty Frith receives the large and important stream of the river Conan, which drains off the waters of Lochs Tolimuir, Garrogan, and Garve; Loch Fannich, Loch Roslik, Lochs Lett, Achin, Hular, and Luichart; Loch Benachan, Loch Scolbuck, and Lochs Negin and Nerick, and Loch Gowrie, by the important tributary river Orrin. Lochs Calavie and Gedd furnish their supplies to the river Beauly of Inverness-shire. Loch Clunie, half of which is in Ross-shire, pays its tribute to Loch Ness by the river Morrison. On the west coast we have the rivers Sheil and Ling, the one tributary to Loch Duich, and the other to Loch Ling; the river Carron discharging into Loch Carron the waters of Lochs Doule and Scaven. In Applecross we have Lochs Lundie and Damph, and the rivers of Applecross and Torridon, the last mentioned discharging itself into Loch Torridon. Loch Vallich, and a great chain of small lakes, empty their waters into Gairloch, as do Lochs Naheig, Padnascally, and Slattadale. The river Ewe, which is only one mile in length, discharges into Loch Ewe the waters of the grand Loch Maree, together with those of Loch Clare and its chain of small lochs, and those of Loch Gurraig; Loch Poolewe also sends its stream into Loch Ewe. Loch Fuir and Loch Shallag have their embouchures in Loch Greinord. The waters of Lochs Arin and Druin find their way into Loch Broom, as do those of Loch Damph and Loch Auchall, and those of Loch Cruisk through the stream of the Strakemort; Loch Kynoch, Loch Lurgan, and Loch Baddagyle send their streams into Loch Enard; and Lochs Skinaskink, Achyle, Vattie, and Fin also discharge themselves into the same bay, at the north-western point of the Coygash part of Cromarty. All these lochs and streams abound with fish, and salmon are particularly abundant in all the rivers, especially in the Oikel and in the Ewe. Short as is the course of this last-mentioned stream, it so swarms with salmon that twenty fish are no uncommon number for an expert angler to take in one day. Loch Maree, from which it derives its stream, is by far the largest and finest lake in Ross-shire. It is eighteen miles long, and from one to three miles broad; and the greater part of it is full sixty fathoms deep, so that it has never been known to freeze even in the most intense frosts. It contains no less than twenty-four islands, and its mountains are magnificent. The highest of the group is Sliabhach or Slioch, which is estimated at about three thousand feet. The Messrs Andersons of Inverness, in their admirable Guide to the Highlands and Islands of Scotland, tell us that the scenery of this lake is the most utterly savage and terrific, in its barrenness and loneliness, of any part of this land of the mountain and the flood. A few ash-trees, oaks, birches, and pines, the latter but remnants of a gigantic ancient forest, are seen along the water's edge, and beautify some of the islands in a high degree. But above this narrow zone scarcely a blade of grass exists, and eternally recurring sheets, precipices, and tables of dark-brown sandstone and quartz rock meet the eye in every direction. Ben Eye, at the south-eastern end, is the only exception, for it consists of two high sharp peaks of pure white quartz rock, and its form is altogether beautiful and stately. The Corries, and the solitudes of Glen Logan, opposite to it, on the other side of the lake, are the favourite haunts of the red deer. Ben Lairg and Stengach, also on the northern shore, are both stupendous mountains: the former recedes to a considerable distance from the margin of the lake, while the latter is visible at once from its base to the summit. Its lower acclivities are remarkably steep, and in one part it presents a front of abrupt lofty cliffs, disposed in great horizontal sections, along the crevices of which a few aged and fantastically shaped pine-trees are seen casting forth their arms against the western breeze. Its rocks contain an unexampled number of varieties of quartz, and the view from its top is unusually grand and extensive. The easiest way to survey its scenery is from a boat. The path on the northern shore by Letterewe is hardly passable, and that on the opposite side is surpassed by none in the Highlands for ruggedness and sterility. It clambers up many rocky channels of torrents, and then, adapting its course to the shelf of a long ledge of sandstone, it stops suddenly over a precipice, leaving the bewildered stranger in utter uncertainty where he is next to step. Yet there are many beauties mingled with all this ruggedness, and some of the numerous little bays are full of the loveliest features of fairy landscape. In the middle of this romantic lake, there is an island, called Island Maree, on which there is a very ancient burying-ground. Some think that it was dedicated to the Virgin Mary, and that, from this circumstance, both the island and the lake derived their name. It contains a number of tombstones covered with inscriptions and hieroglyphical figures, which can hardly now be satisfactorily deciphered. Some of these are believed to be tombs of Danish kings, which induces certain individuals to believe that the name is a corruption from *Eilean-nan-Righ*, or the King's Island; whilst others take it from a good man called Saint Maree, who inhabited this island many generations ago, and of whose benevolent and charitable actions many traditions are still preserved in the surrounding districts. In the centre of the island there is a deep well, dedicated to Saint Mary or Maree. To this a strange superstition attaches. Unhappy maniacs are carried to it and made to drink of its waters; after which they are plunged into the lake, and towed round the island at the stern of a boat, in the absurd hope that they will be thus restored to their senses. Fortunately for humanity, this absurd practice is fast wearing out.

The scenery on the river Conan and some of its tributaries is beautiful and interesting. The falls of Rogie are by many considered as inferior only to those of Foyers and Moness. We may indeed affirm that most of the valleys or river-courses in the united counties are more or less worth visiting, for the wild, the romantic, or the retired pastoral scenes which they contain. The waterfall of Glomach, in the parish of Kintail, is one of the highest and finest in the kingdom. It is to be found in a remote uninhabited valley on the estate of Mr Mackenzie of Applecross, about seven miles from the inn of Sheal-house; and it will well repay the lover of the grandeur of nature for any fatigue or trouble which he may have in visiting it. Its height, lately ascertained, without instruments, but as accurately as the nature of the ground admitted, is about 350 feet. At the height of about fifty feet the water meets with a slight interruption from a shelving projection in the rock. This, however, is a circumstance that adds greatly to the effect, by increasing the volume of spray, and producing variety in the form of the fall. But when the river Girsac is swollen, the sheet of water is unbroken, terrific, and sublime. The fall is best viewed from a solitary tree standing on a narrow neck of rock projecting towards the water, about 100 feet down the ravine, to the south-west of the fall. There the stream appears to issue from an oblong fissure in the rock, from whence, with a fearful rush, it urges its way, chiefly in one great column, to the pool below, from which, at this station, no outlet can be perceived. The environs of the fall are wild and barren, consisting of great naked sheets of perpendicular rocks partially covered with tufts of grass, ferns, or mountain saxifrage, adding, if possible, to the savage character of the scene.

The mountain groups of Ross and Cromarty are very lofty. They rise gradually from the east coast, and more suddenly and boldly from the western sea, to which the summit-level of the country is more generally approximated. The mountains are all of the primitive formation, the secondary strata being found reclining on it on both sides of the island. The granitic series present extremely abrupt sections towards Moray Frith, and there we also find the older and other sandstones, with argillaceous formations abounding in animal remains, with plates resembling those of the tortoise, pieces of rough skin like that of the shark, the scales and bones of fish; and in a ridge of bituminous shale, near the Cromarty rocks, we find ammonites, bellemnites, scallops plain and striated, pieces of wood, and a thick fleshy-looking leaf resembling that of the aloe. The mineralogical catalogue is large. Limestone, and primitive limestone of the character of marble, are very commonly to be met with. Ironstone is disseminated in great abundance. A vein of iron was worked above 150 years ago on the shores of Loch Maree, the works having been discontinued solely from the failure of wood necessary for fuel. There is a rich vein of iron ore in the parish of Alness, and in the same vicinity there is a vein of lead, and indications of that metal have been found in the parish of Kiltearn. A copper-mine at Keeshorn, in the northern district of the parish of Applecross, was considered by Williams as equally rich with any mine of the same metal to be found in Great Britain. On the farm of Scorraig, on the Dundonnell estate, there is a prodigious quantity of bog-iron ore, which gives a strong and harsh chalybeate taste to all the springs in the neighbourhood. There are various mineral springs in the united shires of Ross and Cromarty, but those which have attained the greatest celebrity are the two wells of Strathpeffer, which have now for many years attracted numerous visitors to their neighbourhood in search of health and recreation. Both of these springs have the smell of sulphuretted hydrogen gas, but the upper spring is stronger than the lower. According to Dr Thomson, the temperature of the lower well, on the 24th of June 1824, was 39°, and that of the upper 39¾°, the day being rainy, and the temperature of the air rather under 60°. The specific gravity of the water of these wells was as follows:

Upper well	1·00193.
Lower well	1·00091.

An imperial gallon of the upper spring was found to contain,

Sulphuretted hydrogen gas	26·167	cubic inches.
Sulphate of soda	67·770	grains.
Sulphate of lime	39·454	...
Common salt	24·728	...
Sulphate of magnesia	6·242	...

An imperial gallon of the water from the pump-room yielded

Sulphuretted hydrogen gas......13·659 cubic inches.

The saline contents were similar to those of the upper spring, but in the proportion to them of seven to nine, viz.

Sulphate of soda	52·710	grains.
Sulphate of lime	30·686	...
Common salt	19·233	...
Sulphate of magnesia	4·855	...

Many of the mountains of Ross and Cromarty are of first-rate British magnitude. Scuirvullin is about 2500 feet high. It consists entirely of micaceous schist, inclining in some places to gneiss, and traversed by a few granite and quartz veins. The rocks lie in thin upright stratiform shapes, which dip in opposite directions all round the mountain; and they contain numerous round nodules of quartz, feldspar, and red garnets. All the common alpine plants are to be met with on Scuirvullin. Ben Weavish, or Ben Uaish, that is, the mountain of storm, is one of the most remarkable mountains, not only in Ross and Cromarty, but in Scotland. Its height, by the late trigonometrical survey, is 3720 feet; but it is most wonderful for its immense bulk, by which it stands prominently distinguished from the other hills around it, so as to be peculiarly striking from great distances. Its corries or ravines are never without snow, so that the proprietor can always fulfil his quit-rent by paying a snowball to his sovereign when required to do so, on any day of the year. The primitive rocks of which it is composed are chiefly a gray gneiss, abounding in large scales of mica and garnets, which impart great beauty to the unpolished rock, though they are not sufficiently pure or free from cracks to be used as ornamental stones. The plants which it presents most interesting to the botanist are, *Saxifraga oppositifolia, Arbutus alpina, Azalea procumbens, Betula nana*, &c. Bean Dearig on Loch Broom is 3551 feet in height. It is composed of gneiss, with granite veins and beds of quartz. We might mention many other mountains, but we shall content ourselves with stating, that Tullochard, on the north side of Loch Duich, merits particular notice, from being the crest of the Seaforth family, and from its summit in ancient times being used to blaze with those beacon-fires that raised up the whole country at the will of its lord.

The natural woods in Ross and Cromarty, though much diminished, are still numerous, and widely scattered through the glens and over the mountain sides. The trees are chiefly firs, oaks, ash, birch, and alder. The whole face of the wilder country bears the strongest evidence of its having been once covered with extensive forests, fragments of which only now remain in certain places, whilst the mosses or bogs still preserve the trees which have probably fallen by extensive conflagrations. In the central district, the forest of Fainish still stands, twenty miles in extent. But as these ancient forests are diminishing, artificial plantation, already very extensive, is every day increasing with rapid strides; and in many parts of the country even the soil that is apparently the most barren appears to have a tendency to throw up young plants of birch, and in some places of oak, proving that it is so filled with the seeds or roots of those trees that preservation from sheep and cattle is all that is wanting to restore the ancient natural forests. The island of Lewis is almost entirely destitute of trees.

From the great extent and immense variety of elevation and of surface of Ross and Cromarty, it naturally contains by much the greater part, if not nearly all, the plants to be found in the Flora Scotica; and in the same way, speaking generally, almost all the animals to be found in the zoology of Scotland have been discovered to belong to it. The larger wild quadrupeds are red and roe deer, hares, alpine hares, foxes, badgers, wild cats, &c. Grouse, ptarmigan, black game, and partridges abound; and in some places pheasants have been introduced, and have amazingly increased. We are not aware that any attempt has been as yet made to restore to the older forests that magnificent bird, once indigenous to them, we mean the *Tetrao urogallus*, cappercailzie, or cock of the woods; but such an attempt would be highly desirable, and, from the facility with which the live birds may now be obtained from Norway, it might be made with comparative ease. The golden eagle and the ospray are both common, as well as all the other birds of prey. Water-fowls of all kinds abound on the coasts; and the frith of Cromarty is especially remarkable for the number and variety of sea-fowl which may be obtained by the skilful sportsman. In severe winters it frequently happens that many wild swans are shot there. The list of fishes, both marine and fresh-water, is very ample. Salmon, as already noticed, are especially abundant; and the trouts of Loch Luichart, and many other lakes, are far famed. The pearl mussel, *Mya margaritifera*, is found in the stream of the river Conan, and frequently affords pearls of remarkable beauty. In Strath Conan bees are much cultivated, and a great deal of honey is made in that district.

The landed property of these united counties is chiefly divided into estates, which are more extensive in surface than valuable in rent, the average of them being upwards of 16,000 imperial acres. The whole is valued in the cess-books at L.75,043. 10s. 3d. Scots, and in 1811 the real rent was valued at about L.91,089. 18s. 8d. sterling, affording a mean rental for each estate of not more than L.1075, or about one shilling and fourpence an acre. But we are disposed to think that this last calculation would now be considerably increased, both by the more extensive and better managed occupation of the hills with sheep-farms, and the improvement which has taken place on the agricultural districts. As a sample of the best soil, we may state, that the average rent of arable land in the parish of Dingwall is about L.2 an acre, though some of it is as high as L.4. 10s. The wages of farm-servants in the same district are L.7 or L.8 in money, seven bolls of meal, a quarter of an acre of potatoes, and a free house and garden, altogether worth about L.20. Occasional labourers get about seven shillings and sixpence a week, and country artisans about nine shillings. Mason-work is from L.1. 16s. to L.2 a rood, journeymen being paid about twelve shillings a week. Carpenters are paid from ten to twelve shillings, and slaters about twelve shillings a week. The gentlemen's seats are numerous in Ross and Cromarty, but they are chiefly situated in the eastern or more cultivated districts.

We have already said that the system of agriculture pursued in the more favourable and more strictly agricultural districts of Ross and Cromarty does not fall below the standard of more southern counties. The farms are extensive, and generally let on leases of nineteen years' duration. They are for the most part well enclosed, and the dwelling-houses and other buildings are large and commodious. In the poorer districts, and especially on the west coast, and in Lewis, where the farmers hold only a few acres of arable land, they raise oats, bear or big, and potatoes; and in many places where grazings are attached, they rear a great many cattle and horses of the Highland breed, both of which are often very much stinted in their growth for want of sufficient food in severe winters. Illicit distillation, which once so much occupied these smaller tenants, has now, we believe, been effectually put an end to, chiefly by the introduction of legal small stills. The climate, particularly towards the west coast, may well be termed rather a weeping one; and the carrying of the crops in the western districts is often an exceedingly precarious operation. But where there is so great a variety of surface, we must also look for a great variety of climate. The following meteorological tables, taken from the Statistical Account of the Parish of Dingwall, may furnish a general average view of the climate of the more thickly inhabited districts.

The introduction of steam-navigation has already begun to improve Ross and Cromarty, not only by making them more easily accessible, but by the opening which it has created for the export of cattle and sheep to London. The change in this respect may be readily conceived, when we consider the immense land-journey which the animals had to undergo before they could be brought to the London market. They were driven off in a lean state, and were fed in southern pastures before they could there be produced. Now, a Ross-shire farmer has it in his power to send them direct to the London market, so fed as to be in a condition for immediate slaughter; and thus he is placed on an equality, with regard to expense of transport, with any English farmer who may not be fifty or sixty miles from London. The effect of this in raising the value of property in these and other northern counties may easily be imagined.

The importance of the fisheries to Ross and Cromarty may be estimated from the following table, furnished by Mr Dunsmure, the secretary of the Board of Commissioners for the Herring Fishery.

Account of the quantity of White Herrings and Cod, Ling, or Hake, cured at the stations of Cromarty, Loch Broom, Loch Carron, Loch Shildag, and Stornoway, in the ten years ending 5th April 1839.

Year ending 5th April.	Herrings Cured.	Cod, Ling, or Hake, Cured.		Number of Boats.	Number of Persons.

In the above table, it must be observed that the column of persons employed comprehends not only the fishermen, but the coopers, labourers, gutters, packers, and those engaged in cleaning and drying the fish. It is also to be noticed, that the Loch Carron fishery district includes the Isle of Skye in Inverness-shire. The official brand applied by the officers of the board to the casks of herrings cured and packed, strictly according to the acts of parliament by which the commissioners are guided, is so highly estimated as to give a confidence and a ready sale, and a superiority of price, in all foreign markets, which no herrings can obtain without it. It is therefore becoming every day more and more highly appreciated both by fish-curers and merchants. Every kind of fish that frequents the northern seas may be taken on the coasts of Ross and Cromarty, particularly on those of the island of Lewis. The Broad Bay flounder of Stornoway is the finest in the world. The saithe is much more delicate than the whiting. The haddock is remarkably good. In Lewis, in the parish of Lochs alone, above 100,000 lobsters are sent annually to the London market. Whales, porpuses, and grampuses, are often driven on shore in Lewis in numbers amounting to a hundred and fifty or more, and varying from five to thirty feet in length.

The manufacture of kelp is still extensively practised, especially on the western coast and in Lewis; but the price is now so low and fluctuating, and the time and trouble bestowed in making it so great, that it is believed the sea-weed employed would be much more profitably used as manure.

The burghs of Cromarty, Dingwall, and Tain, along with Dornoch, Wick, and Kirkwall, return a member to parliament. Fortrose and Rosemarkie, two small adjacent towns included in one burgh, return a member along with Inverness, Nairn, and Forres. Besides these burghs, the united county has several villages or small towns in it, such as Contin, Shildag, Dornie, Plocktown, and Ullapool, which last has 500 or 600 inhabitants. Stornoway, in Lewis, is a thriving burgh of barony, with some good streets of houses, and a considerable quantity of shipping, and, with its suburbs and environs, it contains nearly 3000 inhabitants. Sheriff and commissary courts, bailie, excise, and justice of peace courts, are regularly held in it.

In Ross and Cromarty there are many ancient and curious remains. In the parish of Nigg, the site of the castle of Dunskeath, built by William the Lion in the year 1174, is still to be distinguished. At Shandwick is the *Clach-a-Charridh*, or the Stone of the Burial-place. On one side of it a large cross is still to be traced, wrought with an intricate maze of runic knotting. On the sides of the shaft are two animals resembling an elephant and a lion, above each of which there is a figure that appears to lean forward from a cross. On the reverse side of the obelisk there are processions, hunting scenes, and combats. The ground surrounding the spot where it stands was for centuries used as a place of interment. There is a similar though smaller stone in the church-yard of Nigg. It originally stood near the gate, but it was thrown down by the fall of a belfrey in 1725, and it is now fixed to the eastern gable. The top is of a triangular shape, and it has on one side of it two priest-like figures attired in long garments, each furnished with a book, and inclining forward as if intent on reading and devotion. Between them is a small circular table or altar; and a dove seems to descend from above with a circular cake in its bill. Under the table there are two large dogs. Lower down on the stone there is a cross, and the spaces above and below the arms of it are divided into rectangular compartments of mathematical exactness. The hieroglyphics of the opposite side are in lower relief; and in the centre appears the chief figure, that of a man attired in long garments, caressing a fawn, with a lamb and harp directly fronting him. In the space beneath there is a man clashing a pair of cymbals, and a man on horseback surrounded by animals of the chase; while on the upper part of the stone there are dogs, deer, and armed huntsmen, with an eagle or raven surmounting the whole. These obelisks or crosses are supposed to be of Scandinavian origin. Craig-chenichan, or the Rock of Lamentation, in the parish of Kincardine, is memorable for being the place where the Marquis of Montrose was defeated by Colonel Strachan, after which he swam across the Kyle, and lay concealed in Assint, until apprehended and sent prisoner to Inverness. On the summit of Ormondy Hill, 200 feet above the level of the sea, near Castletown Point, in the parish of Avoch, are the foundations of a large and very ancient castle, to which tradition has given the name of Douglas. On a large plain to the westward of the church of Eddertown there are indications of an encampment, where a battle is said to have been fought with the Danes. In its vicinity there is an extensive circle of earth, about two feet higher than the circumjacent ground, flat on the top, with an obelisk in the centre ten feet in height, on which a number of rude figures may still be traced. This is regarded as the tomb of some Danish prince. The abbey and castle of Lochlin, in the parish of Fearn, are remarkable. The former measured ninety-nine by twenty-five feet within the walls. It was used for divine service till October 1742, when the roof fell in and killed thirty-six people. The castle of Lochlin is supposed to be more than five centuries old. It stands on an eminence about six miles to the eastward of Tain. Its plan is that of two squares united at the angles, in which there is a staircase leading to the top of it, which is sixty feet high. The castle of Cadboll, of which little remains, is supposed to be yet more ancient than that of Lochlin. There is a tradition that no one ever died in it; and that about a century and a half ago, a certain Lady May, whose lingering diseases made her long for death, was removed from it at her own request that she might die, and her wish is said to have been gratified immediately after her removal. In the parish of Kirkmichael, and close on the edge of a precipice rising from the shore of Cromarty Frith, is *Tigh-na-Craig*, or the House of the Rock. It is a very curious old building, fifty feet in height, of great antiquity, having been erected by the Urquharts, barons of Cromarty. In Loch Carron are the ruins of Strome Castle; and at Langanduin there is one of those buildings called *Duin*, which are so frequent on the west coast. The castle of Eilean Donnan, on an insulated point between Lochs Ling and Duich, in Kintail, though greatly dilapidated, is still a fine picturesque ruin. It is supposed to have been built in the time of Alexander the Third. It was long the baronial strength of the lords of Kintail; but after the battle of Glensheil in 1719, it was demolished by a ship of war. Some of the cannon-balls fired against it have been found nearly a mile above the castle. Near Ob-Inag, in the parish of Glensheil, is to be found a fine specimen of what has been called the Pictish Tower. At Dingwall are the remains of the ancient castle of the earls of Ross. The hill of Knockfarril, in the parish of Fodderty, is crowned with one of those curious and puzzling morsels of antiquity, usually known by the name of vitrified forts. The walls enclose nearly an acre of level ground, from which Craig Phadric near Inverness, and Dunskaith on the northern Sutor of Cromarty, are distinctly visible, and so it is connected with a chain of these signal-posts. It is probable that the early inhabitants of the country burned their beltane fires on these signal-hills; and these we know were so immense that they might very well account for the vitrification of the circular walls of dry stone which were erected to prevent the fuel from being blown about and dispersed. There are many ancient single stones, and circles of stones, and cairns, in different parts of Ross and Cromarty. In Lewis are to be found the following ruins of religious houses: St Collums in Ui, St Cowstans in Garrabost, and St Aula in Gress. On the Flannel Isles, called by Buchanan *Insulæ Sacræ*, the ruins of religious houses are still extant. At Mealister and Pabay are the remains of nunneries; and there is a similar ruin on the island of St Colme, in the entrance to Loch Erisort. At Carloway there is a fine specimen of those towers already mentioned, perfectly circular, and thirty feet high; and there are three or four more in Barras parish. In the year 1831, a considerable number of little figures, carved in ivory, were found in the sands at the head of the Bay of Uig. We saw them in Edinburgh, and they appeared to us very much to resemble the kings and pieces at chess.

There are many curious caves both on the east and west coasts of Ross and Cromarty; but the most remarkable is the Seal Cave, in the parish of Stornoway, in Lewis, which is considered to be only secondary in grandeur, and in the splendour of its stalactitic formations, to the famous cave in Skye.

The principal clans in Ross and Cromarty are the Mackenzies, Rosses, Frasers, Mackays, Macraes, and Munroes. Gaelic is universally spoken, though it is less used on the eastern than on the western side of the county. In Lewis it is the chief language. The Highland dress is now seldom worn, except on occasions of ceremony or festivity.

The following table contains an abstract of the population of Ross and Cromarty at three different periods.

YEARS.	HOUSES.				OCCUPATIONS.			PERSONS.		
	Inhabited.	Families.	Building.	Uninhabited.	Families chiefly employed in Agriculture.	Families chiefly employed in Trade, Manufactures, and Handicraft.	All other Families not comprised in the two preceding classes.	Males.	Females.	Total of Persons.
1811	12,829	13,574	159	292	7,490	2,499	3,585	27,640	33,213	60,853

1831	15,039	16,187	131	352	8,498	2,611	5,078	34,927	39,893	74,820

(B. P.)

ROSTAK, a city of Arabia, in the district of Ommon. It is the residence of the imaum; but Muskat is the chief town through which the intercourse with the Europeans is carried on. It is situated near Jebel Akdar, the largest and highest mountain in Ommon, and is celebrated for its fine grapes. It is seventy miles west from Muskat.

ROSTOCK, a city of the grand duchy of Mecklenburg-Schwerin, which was formerly the capital of the two duchies of Mecklenburg, but since 1695 it has become the sole possession of the present branch. It is situated on the navigable river Wornow, about eight miles from the Baltic Sea. It is strongly fortified, and contains a citadel, seven churches, 2180 houses of an antique style of building, and about 16,000 inhabitants. It is the place at which the assembly of the states, and the courts of law, are held; and it contains a university founded in 1419, which has a due number of professors, and about a hundred students, to which are attached an observatory, an anatomical theatre, and a library of thirty thousand volumes. It is the most considerable trading place in the German part of the Baltic, and the export of wheat is greater than from any other German port. It has a variety of manufactures for brandy, vinegar, beer, cloths, glass, leather, iron ware, soap, sugar, and linen, and 140 ships belonging to the port. This place gave birth to Prince Blucher, to whom a statue has been erected in the square. Long. 12. 32. E. Lat. 54. 10. N.

ROSTOW, a city of Russia, in the province of Jaroslow, the capital of a circle of its own name, situated on the lake of Nero or Rostow. It contains twenty-four churches, six hospitals, 1016 houses, and 6500 inhabitants; and has extensive trade in corn, hemp, linen, tallow, leather, honey, and wax, and some in salt. It is 530 miles from St Petersburg. Long. 39. 35. E. Lat. 58. 57. N.

ROSTRA, a part of the Roman forum, in which orations, pleadings, and funeral harangues, were delivered. It derived its name from the circumstance of its exhibiting the beaks of ships taken from the Antiates.

ROSTRUM literally denotes the beak or bill of a bird; and hence it has been figuratively applied to the beak or head of a ship.

ROT, a very fatal disease incident to sheep, arising from wet seasons, and too moist pasture. It is very difficult of cure, and is attended with the singular circumstance of a kind of animals being found in the blood-vessels.

ROTA, a city of Spain, in the province of Seville, and the district of St Lucar. It stands on the bay of Cadiz, and being strongly fortified, forms one of the means of defence to that important estuary. It is situated on an elevation, and, like most Spanish towns, has a beautiful appearance when viewed at a distance. It contains some very fine buildings, and about 6500 inhabitants, who partly follow the occupation of fishing, whilst others deal in wine, as this place supplies the kind of red wine known in England by the name of Tent, which is produced on the banks of the river Tinto.

ROTA, the name of an ecclesiastical court of Rome, composed of twelve prelates, of whom one must be a German, another a Frenchman, and two Spaniards; the other eight are Italians, three of whom must be Romans, and the other five a Bolognese, a Ferraran, a Milanese, a Venetian, and a Tuscan. This is one of the most august tribunals in Rome, which takes cognizance, by appeal, of all suits in the territory of the church, and also of all matters, beneficiary and patrimonial.

ROTA ARISTOTELICA, or *Aristotle's Wheel*, denotes a celebrated problem in mechanics, concerning the motion or rotation of a wheel about its axis, so called because Aristotle was the first who took notice of it. The difficulty of it may be represented in the following manner. While the circle makes one revolution on its centre, advancing at the same time in a right line along a plane, it describes on that plane a right line which is equal to its circumference. Now, if this circle carry with it another smaller circle, concentric with it, like the nave of a coach-wheel, then this smaller circle or nave will describe a line in the time of the revolution which shall be equal to that of the large wheel or circumference itself, because its centre advances in a right line as fast as that of the wheel does, being in reality the same with it. Aristotle attempted to solve this problem; but his solution can only be regarded as a good account of the difficulty. It was next attempted by Galileo, who had recourse to an infinite number of infinitely small vacuities in the right line described by the two circles, and imagined that the little circle never applies its circumference to those vacuities, but in reality only applies it to a line equal to its own circumference, though it appears to have applied it to a much larger. This, however, is nothing to the purpose. According to Tacquet, the little circle making its rotation more slowly than the great one, does, on that account, describe a line longer than its own circumference, yet without applying any point of its circumference to more than one point of its base. This is not more satisfactory than the former. After the fruitless endeavours of many great men, M. Dortous de Meyran, a French gentleman, had the good fortune to hit upon a solution which, after being fully examined by a committee of the Academy of Sciences, was declared to be satisfactory. The following is his solution. The wheel of a coach is only acted on or drawn in a right line; its rotation or circular motion arises purely from the resistance of the ground. Now this resistance is equal to the force which draws the wheel in a right line, as it defeats that direction, and therefore the causes of the two motions are equal. The wheel therefore describes a right line on the ground equal to its circumference. On the contrary, the nave is drawn in a right line by the same force as the wheel, but it only turns round because the wheel does so, and can only turn in the same time with it. Hence its circular velocity is less than that of the wheel, in the ratio of the two circumferences, and therefore its circular motion is less than the rectilinear one. Since it must describe a right line equal to that of the wheel, it can only do it by partly sliding and partly revolving, the sliding part being more or less as the nave itself is smaller or greater.

ROTATION.

Rotation, in mechanical philosophy, denotes the motion of the different parts of a solid body about an axis, in contradistinction to the progressive motion of the body in a straight line, or in an orbit about a distant centre, of which the rotation is absolutely independent, although both motions may take place simultaneously. Thus the planets have a progressive motion, or a motion of translation, in the orbits which they describe about the sun, while at the same time each revolves about an axis which passes through its centre of gravity.

In consequence of this double motion of the planetary bodies, the two great problems in physical astronomy are, first, to determine the orbit described in space by each body under the influence of the sun's attraction, but disturbed by the attraction of every other body in the system; and, secondly, to determine the circumstances of the rotation of each body under the influence of the same disturbing forces. This last problem is not of less importance or difficulty than the first. In the case of the earth it includes the determination of the precession of the equinoxes and the nutation of the axis under the disturbing action of the sun and moon; and its analysis has led to the discovery of two important facts connected with the physical constitution of the universe, namely, the invariability of the length of the day, and the permanence of the poles of rotation on the earth's surface.

But the problem of determining the rotation of a solid body is not merely interesting in consequence of its forming a principal part of physical astronomy; it is also one of the highest importance in practical mechanics; for the principles to which we are led in considering the general theory of rotatory motion, enable us to determine the effect or performance of machines, and the proper relations and most advantageous disposition of their several parts, in order to accomplish the object in view with the smallest waste of force, and the least strain or injury to the machine itself.

In treating the subject, we shall first endeavour to demonstrate the fundamental propositions of rotatory motion in as elementary a manner as possible; secondly, we shall show the methods of computing the inertia of bodies of different forms, and the properties of principal axes; thirdly, we shall consider the motion of a body which revolves about a fixed axis, and the properties of the centres of gyration, percussion, and oscillation; and, lastly, we shall give the general equations which determine the rotation of a body acted upon by any number of forces, and which is at liberty to move in any direction.

General principles.

1. When a solid body, or system of material particles, so connected that their mutual distances remain invariable, turns round an axis, every particle describes a circle having its centre in the axis, and its plane perpendicular to the axis; and at every instant of the motion the particle is in the direction of a tangent to the circle, or in a straight line perpendicular to its radius vector. In order, therefore, to ascertain the direction of the motion of any particle of the system, we have only to draw a straight line from the particle perpendicular to the axis of rotation. This line will lie in the plane of the circle, and be its radius vector; and the perpendicular to the radius vector at its extremity gives the direction of the motion of the particle.

2. Since the system is supposed to be invariable in form, every particle describes the circumference of a circle in precisely the same instant of time; and as this is also true of any given portion of the circumference, it follows that the absolute velocities of the different particles are proportional to their distances from the axis of rotation. Hence, if w denote the velocity of the particle whose radius vector or distance from the axis $= 1$, then rw is the velocity of the particle whose distance from the axis $= r$. The velocity denoted by w is called the *angular velocity* of the body; and the rotations of different bodies are compared in respect of velocity by comparing their angular velocities.

3. The nature of the forces which connect the different particles or atoms of a solid body, and render it impossible for any single particle to change its position without a corresponding change in the positions of all the other particles, is very obscurely known; but whatever their nature may be, there is one general fact or law, established by unexcepted experience, which affords a sufficient foundation for a dynamical theory, namely, that the forces by which the particles of a body act reciprocally on each other are equal. An immediate consequence of this law is, that when a solid body is in equilibrium between two external forces A and B, these forces are equal and opposite; for the force A being in immediate equilibrium with the opposite forces exerted by that particle of the solid body to which it is applied, must therefore be equal and opposite to the force resulting from the combination of all the forces which connect that particle with the series of particles immediately adjoining. In like manner, the compound force by which this first series of particles acts on that to which the external force A is applied, is equal and opposite to the compound force which connects this first series with the next series, and so on until we come to the particle to which the external force B is immediately applied. And this particle being in equilibrium, the external force applied to it must be equal and opposite to the compound force exerted on it by the series of contiguous particles on that side; therefore the two forces A and B are equal and opposite.

Hence it follows, that when any number of external forces are applied to a solid body, and it is in equilibrium between them, the forces are such as would be in equilibrium if they were all applied at one point.

4. If a body is maintained in equilibrium by the action of three forces, these forces lie in the same plane, and are either parallel, or meet in the same point. This follows immediately from the composition of forces; for the forces being in equilibrium, any one of the three must be equal and opposite to the equivalent, or *resultant*, as it is termed, of the other two; and this resultant is the diagonal of a parallelogram of which the other two *component* forces are the sides. But the diagonal and sides of a parallelogram are in the same plane, therefore the third force is in the plane of the other two; and, further, since it is equal and opposite to the resultant of the other two, it must be in the same straight line, and consequently pass through their point of concourse. These simple propositions are the foundation of the theory of statics.

5. In applying these propositions to explain the motion of rotation, we must recollect a fundamental theorem in dynamics, that the force which produces any motion is equal and opposite to the force which would prevent it, if applied at the same point, and in the same straight line, or which would extinguish the motion in the same time in which we suppose it to be produced. The force therefore which, acting on any particle, causes the body to revolve about an axis with a given angular velocity, is equal to the force which, if applied at the same point in the opposite direction, would reduce the body to a state of rest in the same time as was necessary to produce the given velocity.

6. The only distinct notion we can form of the intensity of any moving force, is the quantity of motion which

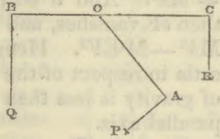
it can produce by acting uniformly during a given time. This will be ascertained when we know the velocity impressed upon a body containing a given quantity of matter. Thus we know that terrestrial gravity acting on a body for a second, will cause it to fall sixteen feet with an uniformly accelerated motion, and will leave it in a state such that it would move on for ever at the rate of thirty-two feet per second. The force of gravity is therefore such as to communicate a velocity of thirty-two feet per second; and in this case the mass of the body is not considered, for gravity acts equally on every particle of which it is composed. In the same manner, the best way of acquiring a distinct conception of the rotatory effect of a moving force, is to determine the quantity of rotatory motion which it can generate by acting uniformly during some known time.

Ro tion of olid boc about an s.

7. If a solid body, or rigid system of invariable form, admit of a rotatory motion about an axis, and if at any point of the body a force P be applied, which acts in a plane perpendicular to the axis of rotation, and tends to turn the body in one direction; and to any other point in the same plane a force Q be applied, tending to turn the body in the opposite direction; then, if the two forces be to each other inversely as the distances of the lines of their directions respectively from the axis, the body will remain at rest, or the two forces will be in equilibrium.

For let O (fig. 1) be the axis of rotation, and suppose the force P to be applied at the point P in the direction PA, and tending to turn the solid body about the axis O perpendicular to the plane of the paper, and let the force Q act in the direction QB, and consequently tend to turn the body in the opposite direction, and draw OA perpendicular to PA, and OB perpendicular to QB. Then, in order that there may be equilibrium, we must have, by the principle of the lever, P : Q : : OB : OA, whence P · OA = Q · OB.

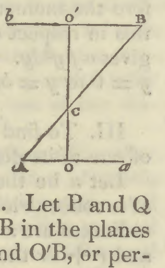
Fig. 1.



8. It is obviously indifferent at what point of the plane the force is applied, provided its distance from the axis remains the same. Let BO therefore be produced, and take OC equal to OA, and draw CR perpendicular to BC, or parallel to BQ. We may now suppose the force P to be replaced by an equal force R, acting in the direction RC; then, since R · OC = P · OA, we have R · OR = Q · OB, and, consequently, the axis being supposed fixed, the body will remain in equilibrium between the two forces Q and R. These forces are therefore equivalent to a single force applied at O, equal to their sum, and acting in a parallel direction. Hence the resultant of two parallel forces applied to a straight line is a force parallel to the component forces, equal to their sum, and whose line of direction divides the straight line into parts reciprocally proportional to the forces themselves.

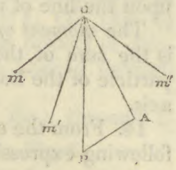
9. If two forces, which are inversely as the distances of their respective directions from the axis of rotation, be applied to a body, the equilibrium will still be maintained, although the two forces are not in the same plane. Let OO′ be two points in the axis of rotation, through which let there be drawn two planes A*a* and B*b* at right angles to the axis. Suppose also these planes to be intersected by another plane (here supposed to be the plane of the figure) passing through the axis, and let OA, O′B be the intersections, and let the straight line which joins A and B intersect the axis in C. Let P and Q be two forces applied respectively at A and B in the planes AO*a* and BO′*b*, and at right angles to OA and O′B, or perpendicular to the plane of the paper, then these two forces are parallel; and because by hypothesis P : Q : : O′B : OA, we have P : Q : : CB : CA; therefore (8) the two forces P and Q are equivalent to a single parallel force passing through C. But a force passing through the axis has no tendency to turn the body round the axis; consequently the body remains at rest.

Fig. 2.



10. Let m, m', m'', &c. (fig. 3) be a system of bodies immoveable in respect of each other, and suppose them to revolve about an axis passing through O; also let m, m', m'', &c. denote the quantities of matter in the bodies respectively, and let r, r', r'', &c. denote their distances from the axis of rotation. Let the angular velocity of the system be w; then (2) the absolute velocities of the bodies are respectively wr, wr', wr'', &c. Now let us suppose the system to be put in motion by an external force F applied at the point P, in the direction PA, which is contained in a plane perpendicular to the axis of rotation; then the relation between the force F and the velocity w may be found as follows. Considering, first, the body m; since its velocity $= wr$, and its quantity of matter $= m$, its quantity of motion $= wrm$. But it is a principle in dynamics, that the quantity of motion of a moving body is proportional to the impressed force, and may be taken as a measure of that force; whence wrm is the measure of a force which, if applied at m, in a direction perpendicular to Om, would cause m to begin to move with the actual velocity wr. Let f be the force which, if applied at P in the direction PA, would make equilibrium with the force wrm at m; draw OA perpendicular to PA, and make OA $= h$. We have then (7)

Fig. 3.



$$f : wrm :: \mathrm{O}m : \mathrm{OA} :: r : h,$$

whence $fh = wr^2m$. In like manner, the quantities of motion in the bodies m', m'', &c. are $wr'm', wr''m''$, &c.; and if we denote by f', f'', &c. the forces which, if applied at P in the direction PA, would respectively make equilibrium with the forces $wr'm', wr''m''$, &c. we shall have $f'h = wr'^2m'$, $f''h = wr''^2m''$, &c.; therefore, if we assume

$$\mathrm{F} = f + f' + f'' +, \&c.$$

we shall have the equation

$$\mathrm{F} \cdot h = w\,(r^2m + r'^2m' + r''^2m'' +, \&c.).$$

If we suppose $m = m' = m'' =$, &c. and take r to denote the distance of any particle from the axis of rotation, the equation becomes $\mathrm{F} \cdot h = w\Sigma\,(r^2m)$; the summation denoted by Σ extending to every particle in the system.

11. When the direction of the external force F is not in a plane parallel to the circles of rotation, it must be resolved into two forces, one of which lies in that plane, and the other is parallel to the axis. It is only the first of these forces which in the present case is regarded as the moving force; the second merely tends to push the body in the direction of the axis, and does not influence the rotation. When we come to consider the rotation of a body perfectly free, it will be necessary to attend particularly to this circumstance.

12. A solid body may be regarded as composed of molecules of a very small but finite magnitude, connected so as to form an invariable system; and although a solid, according to his view of the constitution of body, is formed of discrete elements, the sums relative to the molecules may be changed into definite integrals without sensible error; that is to say, for the sums Σr^2m we may substitute the definite integrals $\int r^2dm$, where dm is the element of the mass, and the integrals extend to the whole mass. We have then $\mathrm{F} \cdot h = w\int r^2dm$.

Moment of a force, and of inertia.

13. The energy of a force applied to a lever, or its power of producing motion round the fulcrum, is expressed by the product of the force into the perpendicular drawn from the fulcrum upon the line of its direction. This product (denoted above by $\mathrm{F} \cdot h$) is called the *moment*, or momentum, or rotatory effort, of the force F. And because $\int r^2dm$ is

Rotation.

the sum of the moments of all the particles of the body in actual motion, this integral expresses the energy or effort of all the resistances made to the rotation by the inertia of the particles, and is therefore called the *moment of inertia* of the moving body with respect to the axis from which the distances r are reckoned. We have therefore these definitions:

The *moment of a force* in respect of a given axis, is the product of the force into the perpendicular from the axis upon the line of its direction.

The *moment of inertia* of a body in respect of any axis is the sum of the products obtained by multiplying each particle of the body into the square of its distance from the axis.

14. From the equation $F \cdot h = w\int r^2dm$ (12), we have the following expression for the angular velocity, namely,

$$w = \frac{F \cdot h}{\int r^2dm};$$

that is to say, the angular velocity about any axis is equal to the moment of the external or applied force divided by the moment of inertia. This fraction expresses a number; for the force F may be represented by the product of a mass M into a certain velocity $= v$, so that $F = Mv$; and therefore, since v represents a line, the numerator and denominator have both the same dimension. The fraction also expresses the part of the radius which is equal to the arc measuring the angle; and since the radius is equal to the arc of 57°·2958, if we make the radius $= 1$, we have only to multiply the fraction by 57·2958 in order to obtain the value of w in degrees.

15. Since the relation between the angular velocity and the external impelling force is expressed in terms of the moment of inertia, it is evident that this moment is an important element in the theory of rotation. We shall therefore now proceed to consider the subject under a more general view, and point out the method by which it is computed for bodies of any form revolving about given axes.

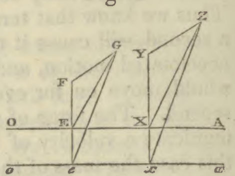
Let the different points of a solid body be referred to three rectangular co-ordinates x, y, z, and let dm be the differential element of the mass; then the distance of any particle from the axis x is $\sqrt{(y^2 + z^2)}$, and, by the definition, the moment of inertia relative to the axis x, is $\int(y^2 + z^2)\,dm$, the integral extending to the whole mass of the body. In like manner, the moments of inertia relative to the axes y and z are respectively $\int(x^2 + z^2)\,dm$ and $\int(y^2 + z^2)\,dm$. It is thus evident that the determination of the moments of inertia, with respect to any body whatever, consists in forming the analytical expression of the product of the differential element of the body into the square of its distance from the axis, and integrating for the whole extent of the body. The integration may always be effected by the method of quadratures.

16. Since the same body may be referred to an infinite number of different axes, in respect of all of which the moments of inertia will have different values, it follows that the moment cannot be absolutely defined unless it be referred to a determinate axis. But when it is required to investigate the moments of inertia of a body in respect of several axes successively, it is not always necessary to compute the formula $\int r^2dm$ for each case. For example, when the moment of inertia has been determined in respect of any one axis, we may find its value in respect of any other parallel axis without further calculation, if we know the mass of the body and the distances of both axes from the centre of gravity.

17. The moment of inertia of any body in respect of an axis AO (fig. 4) being given, to find the moment of inertia in respect of another axis oa parallel to OA.

Let the origin of the rectangular co-ordinates be at O, and let x be taken on the axis OA, and y in the plane of OA and oa. Also let Z be the place of an element dm, and Y the projection of Z on the plane xy; and from Y draw YX perpendicular to OA, meeting OA in X and oa in x; then $OX = x$, $XY = y$, $YZ = z$. The moment of inertia in respect of the axis OA is $\int r^2dm = \int(y^2 + z^2)dm$. But by hypothesis this is given; suppose it $= Mh^2$ (M being the mass of the body), and we have $\int(y^2 + z^2)dm = Mh^2$. In like manner, if we assume the distance of oa from OA to be k, we have $ox = x$, $xY = k + y$, $YZ = z$, and the moment of inertia in respect of oa is $\int\{(k + y)^2 + z^2\}\,dm = k^2\int dm + 2k\int ydm + \int(y^2 + z^2)dm$. But $\int k^2dm = Mk^2$, and $\int(y^2 + z^2)dm = Mh^2$; therefore the moment in respect of the new axis is $Mh^2 + Mk^2 + 2k\int ydm$. Suppose the centre of gravity of the body to be at G; let GF be perpendicular to the plane xy, and draw FE perpendicular to the axes, meeting OA in E and oa in e. From the nature of the centre of gravity $\int ydm = M \cdot EF$; therefore the moment in respect of oa becomes $Mh^2 + Mk^2 + 2k{\cdot}M{\cdot}EF$. But $k = eE$, and $2M{\cdot}k{\cdot}EF = 2M{\cdot}eE{\cdot}EF = M(eF^2 - k^2 - EF^2)$; whence we have finally for the moment of inertia in respect of the new axis oa,

Fig. 4.



$$Mh^2 + M \cdot eF^2 - M \cdot EF^2.$$

Corollary 1. If the original axis OA passes through the centre of gravity G, then EF vanishes, and the moment in respect of the new axis oa becomes $Mh^2 + M{\cdot}eF^2$, or $Mh^2 + Mk^2$. And if oa passes through the centre of gravity, then eF vanishes, and the moment in respect of oa becomes $Mh^2 - M{\cdot}EF^2$. Hence we infer that the moment of inertia in respect of the axis which passes through the centre of gravity is less than the moment in respect of any other parallel axis.

Corol. 2. The moment of inertia is the same in respect of every axis parallel to that which passes through the centre of gravity, and is at the same distance from it; or the same in respect of every straight line which lies in the surface of a cylinder having the centre of gravity in its axis.

Example
of the co
putation
moments
of inerti

18. We shall now give a few examples of the application of the preceding formulæ.

I. Let it be proposed to find the moment of inertia of a very slender rod (the breadth and thickness of which may be neglected), in respect of an axis passing through its extremity and perpendicular to its length.

Let $a =$ the length of the rod, and $x =$ the distance of any point from the axis, then the element of the body is dx, and the moment of inertia $= \int x^2dx$, the limits of the integral being $x = 0$ and $x = a$. For those limits we have $\int x^2dx = \frac{1}{3}a^3$, which therefore is the moment of inertia.

II. To find the moment of inertia of a very thin rectangle, the thickness of which may be neglected, in respect of an axis coinciding with one of its sides.

Let the side which coincides with the axis $= a$, and the other side $= b$, and let x be taken in the axis. The co-ordinates of any point in the rectangle being x, y, the element of the body is $dxdy$, and the distance from the axis $= y$, therefore the moment of inertia is $\int\int y^2dxdy$. The integral of this in respect of x is $\int xy^2dy$, which from $x = 0$ to $x = a$ gives $a\int y^2dy$. A second integration gives $\frac{1}{3}ay^3$, which from $y = 0$ to $y = b$, becomes $\frac{1}{3}ab^3$; therefore, since $M = ab$,

$$\int\int y^2dxdy = \tfrac{1}{3}ab^3 = \tfrac{1}{3}M \cdot b^2.$$

III. To find the moment of inertia of a circle in respect of one of its diameters.

Let a be the radius of the given circle, $r =$ the radius of a concentric circle passing through a point P whose co-ordinates are x and y, x being taken on the axis of rotation, and $r + dr$ the radius of a second concentric circle, very near the other. If we now assume $dz = \sqrt{(dx^2 + dy^2)}$, then $dz \cdot dr$ is the area of the elementary surface included between the circumferences of the two circles whose radii are respectively r and $r + dr$, and two straight lines drawn from the centre to the extremities of a very small arc at P; that is to say, we have $dm = dzdr$. But the distance of this element from the axis is y; therefore the moment of inertia is $\int\int y^2dzdr$. Now, by the nature of the circle, $dz : dx :: r : y$, whence $ydz = rdx$, and the double integral becomes $\int ydx \times \int rdr$. Now, on the supposition that r is constant, the integral $\int ydx = \pi r^2 =$ area of the circle whose radius is r; therefore the integration in respect of dx gives $\pi \int r^3dr$; and on integrating this from $r = 0$ to $r = a$, we get ultimately $\frac{1}{4}\pi a^4$ for the moment of the circle whose radius is a.

Since in this case the mass $M = \pi a^2 =$ the area, we have $\frac{1}{4}\pi a^4 = \frac{1}{4}Ma^2$, which is another expression for the moment of inertia of a circle in respect of one of its diameters.

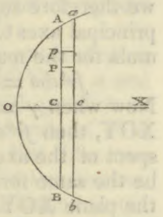
IV. To find the moment of inertia of a circle in respect of an axis perpendicular to its plane, and passing through its centre.

Supposing, as in the last proposition, the surface to be composed of elementary rings, we have $dm = dzdr$, whence $\int r^2dm = \int r^2dr \times \int dz = 2\pi \int r^3dr$ (since $\int dz = 2\pi r$), the integral of which, from $r = 0$ to $r = a$, gives $\int r^2dm = \frac{1}{2}\pi a^4 = \frac{1}{2}Ma^2$.

V. To find the moment of inertia of a solid body generated by the revolution of a curve line in respect of the axis of rotation.

Let AB (fig. 5) be a section perpendicular to the axis of rotation OX, and meeting it in C, and make $OC = x$. Suppose the solid to be divided into thin slices by planes parallel to AB, and let ab be the section next to AB, so that $Cc = dx$. Let P be a point in the plane AB, and make $CP = r$, $Cp = r + dr$. The length of the circumference described by P in one revolution is $2\pi r$, therefore the mass of the ring comprised between AB and ab, and traced by the revolution of the points P and p, is $2\pi rdrdx$; and its distance from the axis is r, therefore the moment of inertia of the ring is $2\pi r^3drdx$. Integrating this in respect of r from $r = 0$ to $r = CA = y$, we get $\frac{1}{2}\pi y^4dx$ for the moment of the slice comprised between the two sections of the solid, whose distances from O are x and $x + dx$. Hence the moment of inertia of all the slices, or of the solid body, is $\frac{1}{2}\pi\int y^4dx$.

Fig. 5.



Applying this formula to a sphere whose radius $= a$, we get from the equation $y^2 = 2ax - x^2$, $y^4 = 4a^2x^2 - 4ax^3 + x^4$, on substituting which, and integrating, we have $\frac{1}{2}\pi\int y^4dx = \frac{2}{3}\pi a^2x^3 - \frac{1}{2}\pi ax^4 + \frac{1}{10}\pi x^5$, which from $x = 0$ to $x = a$ gives $\frac{1}{2}\pi\int y^4dx = \frac{4}{15}\pi a^5$ for the hemisphere, and consequently the moment of inertia of the whole sphere $= \frac{8}{15}\pi a^5 = \frac{2}{5}M \cdot a^2$, since $M = \frac{4}{3}\pi a^3$.

The moment of inertia of a spheroid revolving about its shorter axis is $\frac{1}{5}M(a^2 + b^2)$. See the calculation of $\int x^2dm$ and $\int y^2dm$ in this case in the article PRECESSION, vol. xviii. p. 508.

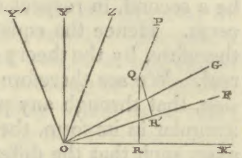
In all the preceding examples, the density of the body has been supposed uniform, and $= 1$. For bodies of different densities the formulæ must be multiplied in each case by the density. Thus, in the last example, the moment of inertia of a sphere whose radius $= a$, and density $= \varrho$, the moment of inertia in respect of one of the diameters is $\frac{8}{15}\pi\varrho a^5$.

19. The examples which have now been given will suffice to illustrate the method of computing the moments of inertia of bodies of any form in respect of particular axes; and they render it obvious that the computation will in general be greatly facilitated when the mass is symmetrically disposed about the axis for which the inertia is to be computed. It is likewise evident that the amount of rotatory inertia depends on the position of the axis of rotation. Hence, for every point of a mass there must exist at least one axis in respect of which the inertia is less, or greater, than in respect of any other axis passing through that point. The axes for which the moments of inertia are the greatest or least possible are called *principal axes;* and they possess some very remarkable properties of great importance in the theory of rotation. We now proceed to investigate the position and properties of the principal axes.

20. The moments of inertia of a mass M being given in respect of three rectangular axes OX, OY, OZ (fig. 6) passing through O, to find the moment in respect of another axis OG given in position, and also passing through the origin O.

Let P be the position of a particle dm; through P draw PQ parallel to the axis OZ, meeting the plane XOY in Q, and draw QR parallel to OY, meeting OX in R; then $OR = x$, $RQ = y$, $QP = z$. Also suppose the plane which passes through OG, and is perpendicular to XOY, to meet the plane XOY in OF, and let the angle $XOF = \varphi$, and the angle $FOG = \psi$. The axis OG is entirely determined by these two angles, and consequently, when OG is given in position, φ and ψ are also given. In order to compute the moment of inertia in respect of the axis OG, it is convenient to refer the different points of the mass, as P, to a new system of rectangular axes, of which one is OG. To effect this, in the first place let OY be drawn perpendicular to OF in the plane XOY, and let P be referred to the axes OF, OY′, OZ, and draw QR′ perpendicular to OF. We have then $OR' = x'$, $R'Q = y'$, $QP = z$, and the new co-ordinates expressed in terms of the former, and the angles φ and ψ are

Fig. 6.



$x' = x \cos. \varphi + y \sin. \varphi$, $y' = y \cos. \varphi - x \sin. \varphi$, $z' = z$.

In the second place, we may pass in like manner from these to a third system of co-ordinates x'', y'', z'', of which x'' is in the line OG, y'' remains parallel to OY′, and z'' is perpendicular to OG in the plane FOG. We have, then, similarly,

$x'' = x' \cos. \psi + z' \sin. \psi$, $y'' = y'$, $z'' = z' \cos. \psi - x \sin. \psi$.

Substituting in these last equations the values of x', y', and z', given by the three former, we have

$$x'' = x \cos. \varphi \cos. \psi + y \sin. \varphi \cos. \psi + z \sin. \psi,$$
$$y'' = y \cos. \varphi - x \sin. \varphi,$$
$$z'' = z \cos. \psi - x \cos. \varphi \sin. \psi - y \sin. \varphi \sin. \psi.$$

If we now assume the distance of P from the axis OG to be r, we shall have $r^2 = y''^2 + z''^2$; whence, on forming from the two last equations the expression for $\int r^2dm = \int (y''^2 + z''^2)\, dm$, and, for the sake of abridging, putting

$$\int x^2dm = A, \int y^2dm = B, \int z^2dm = C,$$
$$\int xydm = D, \int xzdm = E, \int yzdm = F,$$

the expression for the moment of inertia in respect of the axis OG becomes

$$\begin{aligned} \int r^2dm = {} & A (\sin.^2 \varphi + \cos.^2 \varphi \sin.^2 \psi) \\ & + B (\cos.^2 \varphi + \sin.^2 \varphi \sin.^2 \psi) + C \cos.^2 \psi \\ & - 2 D \cos. \varphi \sin. \varphi \cos.^2 \psi - 2 E \cos. \varphi \cos. \psi \sin. \psi \\ & - 2 F \sin. \varphi \cos. \psi \sin. \psi. \end{aligned}$$

This expression for the moment of inertia in respect of the axis OG is given by Euler (*Theoria Motus Corporum Solidorum*, p. 169).

21. The values of the angles φ and ψ, which give the position of the axis for which the moment $\int r^2dm$ is a maximum or minimum, may be deduced from the above equation in the usual manner, that is to say, by differentiating successively for each of the variables, and making the differential co-efficient $= 0$. The differentiation in respect of φ (supposing ψ constant) gives the equation

$$\tan. \psi = \frac{-(A - B) \sin. \varphi \cos. \varphi + D (\cos.^2 \varphi - \sin.^2 \varphi)}{E \sin. \varphi - F \cos. \varphi},$$

and the differentiation in respect of ψ (supposing φ constant) gives

$$\tan. 2\psi = \frac{2 \tan. \psi}{1 - \tan.^2 \psi}$$

$$= \frac{2 \text{E} \cos. \varphi + 2 \text{F} \sin. \varphi}{\text{A} \cos.^2 \varphi + \text{B} \sin.^2 \varphi - \text{C} + 2 \text{D} \cos. \varphi \sin. \varphi}.$$

On eliminating ψ from these two equations, there results an equation of the following form, in which $u = \tan. \varphi$, and e, f, g, h, are co-efficients depending upon the quantities A, B, C, D, E, F, viz.

$$0 = e + fu + gu^2 + hu^3.$$

This being a cubic equation, must have at least one real root. But it is easy to see, from the nature of the thing, that all the roots are real; for if there be one axis for which the moment of inertia is a *maximum*, there must evidently be a second, in respect of which it is a *minimum*, and *vice versa*. Hence the equation must have two real roots, and therefore, by the theory of cubic equations, all the roots are real. We are therefore led to this very important conclusion, that through any point of every solid body, however irregular in its form, there may be drawn a system of three axes, such that the differential co-efficient of the moment of inertia in respect of each of them is nothing. In respect of one of these, the moment is a maximum, in respect of another, it is a minimum, and though, in respect of the third it is neither a maximum nor a minimum, it is still such that its value is not altered by a small change in the position of the axis. According to the definition in (19), these are the *principal axes* of the body.

Properties of principal axes.

22. It would be difficult, in general, to determine the position of the principal axes from the cubic equation found above; but they possess certain properties, by means of which they may be readily found in almost every case of practical application. On comparing the two equations for $\tan. \psi$ and $\tan. 2\psi$ (21), with the expressions for x', y'', z'' (20), it will be seen that the first is identical with $2 \cos. \psi \int x''y''dm$, and the second with $-2\int x''z''dm$; whence $\int x''y''dm = 0$, and $\int x''z''dm = 0$; and it follows, that if x be taken in one of the principal axes, we have, in respect of that axis, $\int xydm = 0$, $\int xzdm = 0$, or the quantities denoted by D and E respectively vanish.

23. From this it follows, that if all the matter in a body of uniform density be symmetrically disposed about any line, that line is one of the principal axes of rotation (for if x be taken in the axis of symmetry, then to every element whose co-ordinates are x, y, there corresponds another element whose co-ordinates are x, $-y$, whence $\int xydm = 0$); therefore, in the case of symmetrical figures, the position of one of the principal axes is known, and the positions of the other two are thence readily determined by means of the two equations (21). On making $\text{D} = 0$, $\text{E} = 0$, the first of these equations gives

$$(\text{A} - \text{B}) \sin. \varphi \cos. \varphi - \text{F} \cos. \varphi \tan. \psi = 0,$$

whence $\cos. \varphi = 0$, and $\sin. \varphi = 1$; or $\varphi = 90°$. Substituting this value of φ in the second of the equations (21), and making at the same time $\text{D} = 0$, $\text{E} = 0$, we get $\tan. 2\psi = 2\text{F} \div (\text{B} - \text{C})$; or 2ψ is the angle which has $2\text{F} \div (\text{B} - \text{C})$ for its tangent. Hence the angle ψ has a double value, one corresponding to FOG, and the other to FOG + 90°.

24. Hence also it appears, that when one principal axis OX is determined, two others may be found having the same property of maximum or minimum, and, by reason of $\varphi = 90°$, these axes are both in a plane perpendicular to OX. As this conclusion holds good with respect to each of the three axes, it follows that the three principal axes are at right angles to each other, and also, since $\int xydm = 0$, and $\int xzdm = 0$, that $\int yzdm = 0$. We have therefore, in respect of the principal axes, the three equations

$$\text{D} = \int xydm = 0, \ \text{E} = \int xzdm = 0, \ \text{F} = \int yzdm = 0.$$

If the origin of the co-ordinates is placed at the centre of gravity, we have likewise

$$\int xdm = 0, \int ydm = 0, \int zdm = 0,$$

by the well-known property of the centre of gravity.

25. By means of these equations, the proposition in (20) is considerably simplified when the three axes for which the momenta are respectively given are principal axes. Let OX, OY, OZ (fig. 6) be the three principal axes passing through O, then $\text{D} = 0$, $\text{E} = 0$, $\text{F} = 0$, and the equation (20) for the moment, in respect of the axis OG, becomes

$$\int r^2dm = \text{A} (\sin.^2 \varphi + \cos.^2 \varphi \sin.^2 \psi)$$
$$+ \text{B} (\cos.^2 \varphi + \sin.^2 \varphi \sin.^2 \psi) + \text{C} \cos.^2 \psi.$$

Suppose the given moments in respect of the principal axes to be respectively $\text{M}{\cdot}a^2$, $\text{M}{\cdot}b^2$, $\text{M}{\cdot}c^2$; then, from the values of A, B, C (20) we have $\text{M}{\cdot}a^2 = \text{B} + \text{C}$, $\text{M}{\cdot}b^2 = \text{A} + \text{C}$, $\text{M}{\cdot}c^2 = \text{A} + \text{B}$, whence

$$\text{A} = \tfrac{1}{2} \text{M} (b^2 + c^2 - a^2), \ \text{B} = \tfrac{1}{2} \text{M} (a^2 + b^2 - c^2),$$
$$\text{C} = \tfrac{1}{2} (a^2 + c^2 - b^2),$$

on substituting which in the above equation, we get

$$\int r^2dm = \text{M} (a^2 \cos.^2 \varphi \cos.^2 \psi + b^2 \sin.^2 \varphi \cos.^2 \psi + c^2 \sin.^2 \psi).$$

If we now refer the new axis OG to the co-ordinates OX, OY, OZ, and make the angle $\text{XOG} = \alpha$, $\text{YOG} = \beta$, $\text{ZOG} = \gamma$, and observe that because the two planes XOF and FOG are at right angles, $\cos. \alpha = \cos. \varphi \cos. \psi$, $\cos. \beta = \sin. \varphi \cos. \psi$, $\cos. \gamma = \sin. \psi$, the equation becomes

$$\int r^2dm = \text{M} (a^2 \cos.^2 \alpha + b^2 \cos.^2 \beta + c^2 \cos.^2 \gamma).$$

It is to be remarked, that as the co-ordinates are rectangular, $\cos.^2 \alpha + \cos.^2 \beta + \cos.^2 \gamma = 1$, so that the position of OG is determined by any two of these angles. If we therefore suppose the moments in respect of two of the principal axes to be equal, for example, if $a^2 = b^2$, the formula for the moment in respect of OG becomes

$$\int r^2dm = \text{M}{\cdot}a^2 (1 - \cos.^2 \gamma) + \text{M}{\cdot}c^2 \cos.^2 \gamma.$$

Now when $\gamma = 90°$, that is, when OG lies in the plane XOY, then $\int r^2dm = \text{M}{\cdot}a^2$. Hence, if the moments in respect of the axes OX and OY be equal, the moment will be the same for every axis passing through O, contained in the plane XOY.

When the moments in respect of the three principal axes are equal, that is, when $a^2 = b^2 = c^2$, then

$$\int r^2dm = \text{M}{\cdot}a^2 (\cos.^2 \alpha + \cos.^2 \beta + \cos.^2 \gamma) = \text{M}{\cdot}a^2,$$

so that the moment is the same in respect of any axis whatever which passes through O. Thus it appears, that for every point of a solid body there are either three principal axes of rotation only, or else an infinite number.

26. These conclusions are obviously true in the case of some simple figures. Thus, in the spheroid of revolution, the moments are equal in respect of every diameter which lies in the plane of the equator; and in the sphere they are the same in respect of any diameter whatever, the bodies being always supposed homogeneous. The existence of three principal axes in every body was first noticed by Segner in 1755, but demonstrated for the first time by Albert Euler, in a memoir which received the prize of the Academy of Sciences of Paris in 1760.

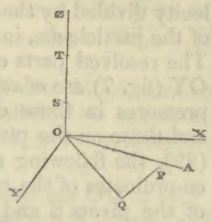
Rotation about a fixed axis.

27. Having established these general propositions respecting the moments of inertia and principal axes of bodies endowed with a rotatory motion, we now proceed to consider more particularly the rotation of a solid body about a fixed axis.

When a force is impressed on a body which can only move round a fixed axis, the difference between the motion which actually takes place, and that which would take place if the body were free, is evidently owing to the connexion which its parts have with the axis, and to the action of the points of support upon the axis. This action must be viewed in the light of another external force, such that, if combined with the force impressed on the body, it would produce in the body unconnected with any fixed points the motion which actually takes place.

28. In order to determine the strain on the axis, let OY (fig. 7) be the axis of rotation, retained in a fixed position by the two pivots S, T, and suppose a force = F applied to the body at P, in the direction PQ, which is supposed to lie in a plane perpendicular to OZ. In the plane perpendicular to the axis, and containing PQ, let the rectangular axes OX, OY be drawn, and let x, y, z be the co-ordinates of a particle dm, the projection of which on the plane XY is at A, and let r denote its distance from the axis of rotation, so that $r = \mathrm{OA} = \sqrt{(x^2 + y^2)}$; also let $\varphi =$ the angle which OA makes with OX. If we now suppose w to be the angular velocity communicated to the body, then rw is the velocity with which the point A revolves, and the direction of this velocity is in the perpendicular to OA, and from OX towards OY, whence the velocity of A in the direction OX is $- wr \sin. \varphi$, and $wr \cos. \varphi$ in the direction OY. But $r \sin. \varphi = y$, and $r \cos. \varphi = x$; therefore the velocity of A in the direction OX is $-wy$, and in the direction OY it is $+ wx$. The quantities of motion in these directions are therefore respectively $- wydm$ and $+ wxdm$; and the integrals of those expressions extended to the whole mass of the moving body give the whole quantities of motion in those directions, namely, $- w\int ydm$, and $+ w\int xdm$. On denoting the mass by M, and the co-ordinates of its centre of gravity by x_1 and y_1, we have (from the well-known expressions for these co-ordinates) $\int ydm = \mathrm{M}y_1$, and $\int xdm = \mathrm{M}x_1$, therefore $- w\int ydm = - w\mathrm{M}y_1$, and $+ w\int xdm = + w\mathrm{M}x_1$.

Fig. 7.



29. Now, since the body is supposed to be put in motion by a force F acting in a plane parallel to XOY, let α and β be the angles which its direction makes with parallels to OX and OY respectively; then the components of F in those directions are $\mathrm{F} \cos. \alpha$ and $\mathrm{F} \cos. \beta$. But these two forces are evidently equal respectively to the two former, together with the pressures on the pivots estimated in the same directions; therefore, calling p and q the pressures sustained by the point S in the directions OX and OY, and p', q' the pressures sustained by T in the same directions, we shall have

$$p + p' = \mathrm{F} \cos. \alpha + w\mathrm{M}y_1,\ q + q' = \mathrm{F} \cos. \beta - w\mathrm{M}x_1.$$

In order to determine p, p', q, q', it is still necessary to find two other equations. These will be obtained by considering, that in respect of the plane XOY, the moments of the forces acting on the two pivots, resolved in the directions x and y, must be equal to the moments of the resultants of all the forces or quantities of motion due to the rotation estimated in the same directions. Let $k = \mathrm{OS}$, and $k' = \mathrm{OT}$, the moments of the resolved forces which act on the pivots in the directions parallel to OX and OY are $pk + p'k'$ and $qk + q'k'$; and the resultants of the quantities of motion in the same two directions being $- w\int ydm$ and $+ w\int xdm$, their moments in respect of the plane OXY are respectively $- w\int yzdm$ and $+ w\int xzdm$; therefore

$$pk + p'k' = - w\int yzdm,\ qk + q'k' = + w\int xzdm.$$

Combining these with the preceding two equations, p, p', q, y' are obtained in terms of known quantities.

30. If the axis of rotation OZ be one of the principal axes of the system which intersect at O, then, by (24), $\int yzdm = 0$ and $\int xzdm = 0$, whence $pk + p'k' = 0$, and $qk + q'k' = 0$, and consequently k and k' both vanish, and the percussions sustained by the axis pass through the origin O. Let R represent the single force or shock which the axis supports in this case, and φ the angle which its direction makes with the axis OX; then, by (29),

$$\mathrm{R} \cos. \varphi = \mathrm{F} \cos. \alpha + w\mathrm{M}y_1,\ \mathrm{R} \sin. \varphi = \mathrm{F} \cos. \beta - w\mathrm{M}x_1,$$

from which two equations R and φ are both determined.

Application to machines.

31. It would be a desirable thing in machines which derive their efficacy from a rotatory motion, to apply the pressures arising from the power and from the resistance opposed by the work in such a manner as to annihilate or diminish this pressure on the supports of the axis of motion. Attention to this theorem will point out what may be done; and it is at all times proper, nay necessary, to know what are the pressures in the points of support. If we are ignorant of this, we shall run the risk of our machine failing in those parts; and our anxiety to prevent this will make us load it with needless and ill-disposed strength. In the ordinary theories of machines, deduced entirely from the principles of equilibrium, the pressure on the points of support (exclusive of what proceeds from the weight of the machine itself) is stated to be the same as if the moving and resisting forces were applied immediately to these points in their own directions. But this is in all cases erroneous; and, in cases of swift motions, it is greatly so. We may be convinced of this by a very simple instance. Suppose a line laid over a pulley, and a pound weight at one end of it, and ten pounds at the other; the pressure of the axis on its support is eleven pounds, according to the usual rule; whereas we shall find it only $3\frac{7}{11}$. For the direction of the pressure R being in this case parallel to the axis y, and the force F also acting in the same direction, we have $\cos. \varphi = 0 \cos. \alpha = 0$, $\sin. \varphi = 1$, $\cos. \beta = 1$, $y_1 = 0$, and the two equations of (30) give the single equation

$$\mathrm{R} = \mathrm{F} - w\mathrm{M}x_1.$$

If we now call the radius of the pulley 1, the moment of the moving force is $10 \times 1 - 1 \times 1 = 9$; and the moment of inertia (13) is $10 \times 1^2 + 1 \times 1^2 = 11$; therefore (14) the angular velocity $w = \frac{9}{11}$. But the distance of the centre of gravity from the axis of motion is also $\frac{9}{11}$, because the two weights may be supposed in contact with the circumference of the pulley; therefore, since $\mathrm{M} = 11$, $w\mathrm{M}x_1 = \frac{9}{11} \times \frac{11}{1} \times \frac{9}{11} = \frac{81}{11}$. Now $\mathrm{F} = 10 + 1 = 11$, therefore $\mathrm{R} = 11 - \frac{81}{11} = \frac{40}{11} = 3\frac{7}{11}$ pounds, which is the pressure sustained by the axis.

32. If we suppose $\mathrm{R} = 0$, the two equations (30) will express the conditions that must be fulfilled in order that the axis may receive no shock from the action of the impressed force F. This supposition gives the equations

$$\mathrm{F} \cos. \alpha = - w\mathrm{M}y_1,\ \mathrm{F} \cos. \beta = w\mathrm{M}x_1,$$

from which, since $\cos. \beta = \sin. \alpha$, we deduce

$$- y_1 \sin. \alpha = x_1 \cos. \alpha, \text{ or } - y_1 \tan. \alpha = x_1.$$

Now, if a plane be conceived to pass through the axis OZ and the centre of gravity of the body, and if we denote by ψ the angle which it makes with the plane XOZ, we shall have $x_1 = y_1 \tan. \psi$; and therefore, since $x_1 = - y_1 \tan. \alpha$, $\tan. \psi = - \tan. \alpha$. From this equation it follows that the direction PQ of the impressed force is perpendicular to the plane which passes through the axis and the centre of gravity. It now remains only to find the distance of the point of impulse P from the axis. Let $h =$ this distance, and $r_1 =$ distance of centre of gravity from the axis; the above equations give $\mathrm{F}^2 \cos.^2 \alpha = w^2\mathrm{M}^2y_1{}^2$, $\mathrm{F}^2 \sin.^2 \alpha = w^2\mathrm{M}^2x_1{}^2$, whence $\mathrm{F}^2 = w^2\mathrm{M}^2(x_1{}^2 + y_1{}^2) = w^2\mathrm{M}^2r_1{}^2$, and $\mathrm{F} = w\mathrm{M}r_1$. But (14) $w = \mathrm{F}{\cdot}h \div \int r^2dm$; therefore, by substitution,

$$\mathrm{F} = \mathrm{F}{\cdot}h\mathrm{M}r_1 \div \int r^2dm, \text{ and consequently } h = \frac{\int r^2dm}{\mathrm{M}r_1}.$$

33. Hence it appears that the conditions which must be fulfilled in order that the axis may receive no shock when the body is struck, are, 1*st*, that the direction of the force be in the plane of the two axes which make with the axis of rotation a system of principal axes; 2*d*, that its direction be perpendicular to the plane which passes through the axis and the centre of gravity; and, 3*d*, that the distance of the point of its application from the axis be $\int r^2dm \div \mathrm{M}r_1$.

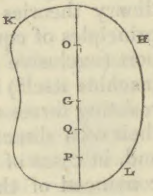
Centre of percussion.

34. The point determined by these conditions is called the *centre of percussion* of the system. The centre of per-

cussion is therefore the point at which, if an obstacle were opposed sufficient to resist the rotation of the system, no motion would be communicated to the axis; or, which is the same thing, if the axis were not fixed, the system would acquire from the shock no tendency to turn, the effect being the same as if the whole rotatory effort had been accumulated at that point.

Let HKL (fig. 8) be a section of the body perpendicular to the axis, and containing the centre of gravity G. Let O be the axis, and in the line OG take $OP = h = \int r^2dm \div M{\cdot}OG$, then P is the centre of percussion, and a force applied at P, in the plane HKL, and in the direction perpendicular to OP, will produce the same initial velocity of the centre of gravity G as if the body were free; for as the force exerts no pressure on the axis or points of support, the initial velocity will be the same as if they were not there.

Fig. 8.



35. The distance of the centre of percussion from the axis is always greater than the distance of the centre of gravity from the axis; for the moment of inertia in respect of the axis passing through O being $\int r^2dm$, by (17) the moment of inertia in respect of the parallel axis passing through G is $\int r^2dm - M{\cdot}OG^2$; therefore, since the moment of inertia is necessarily positive, $\int r^2dm \geq M{\cdot}OG^2$. But by the definition $\int r^2dm = M{\cdot}OG{\cdot}OP$, therefore $M{\cdot}OG{\cdot}GP \geq M{\cdot}OG^2$, or $OP \geq OG$.

36. The property of the centre of percussion, that a force applied there produces no strain on the axis, may be rendered sensible by a simple experiment. If a straight line, or rod of uniform thickness, be suspended from one extremity, the centre of percussion is at the distance of two thirds of its length from the axis; for the centre of gravity being at the middle of the line, $OG = \frac{1}{2}$, so that if we call its mass $M = 1$, the formula $OP = \int r^2dm \div M{\cdot}OG$ becomes $OP = 2\int x^2dx$, which, on taking the integral from $x = 0$ to $x = l$, gives $GP = \frac{2}{3}l$. Now if the rod be held in the hand, and we give it a motion round the joint of the wrist only, and strike smartly against an obstacle with a point considerably nearer or more remote than two thirds of its length, we feel a painful shock or wrench in the hand; but if we strike with that point which is exactly at two thirds of its length, we feel no such disagreeable strain.

37. It is sometimes said that the point P, considered as the centre of percussion, is that with which the most violent blow is struck. But this is by no means true. P is that point of a body turning round O which gives a blow precisely equal to the progressive motion of the body, and in the same direction. As we have already said, it is the point where we may suppose the whole rotatory momentum of the body accumulated. Every particle of the body is moving in a particular direction, with a velocity proportional to its distance from the axis of rotation; and if the body were stopped in any point, each particle tending to continue its motion endeavours to drag the rest along with it. Whatever point we call the centre of percussion should have this property, that when it is stopped by a sufficient force, the whole motion and tendency to motion of every kind should be stopped; so that if at that instant the supports of the axis were annihilated, the body would remain in absolute rest.

38. The expressions in (29) for the stress on the axis have reference only to the initial movement of the body, and the forces which they represent are soon destroyed by the resistance of the axis. But when a body is in permanent rotation about a fixed axis, there is a strain exerted on the axis which depends only upon the centrifugal force of rotation, and which therefore continues as long as the rotation continues. This constant pressure is determined as follows: Since w is the angular velocity, and r the distance of a particle dm from the axis, the velocity of the particle $= rw$; and, by mechanics, the centrifugal force of a body moving in a circle is proportional to the square of the velocity divided by the radius; therefore the centrifugal force of the particle dm, in the direction of the radius r, is w^2rdm. The resolved parts of this force in the directions OX and OY (fig. 7) are w^2xdm and w^2ydm; therefore, denoting the pressures in those directions on the pivot S by p and q, and those on the pivot T by p' and q', we shall have, as in (29), the following equations (in which x_1 and y_1 are the co-ordinates of the centre of gravity, and k, k' the distances of the pivots S and T respectively from O) to determine p, p', q, q', viz.

$$p + p' = w^2\int xdm = w^2Mx_1,\ q + q' = w^2\int ydm = w^2My_1,$$
$$pk + p'k' = w^2\int xzdm,\ qk + q'k' = w^2\int yzdm.$$

If we suppose OZ to be one of the three principal axes passing through O, then (22) $\int xzdm = 0$ and $\int yzdm = 0$; whence $pk + p'k' = 0$, $qk + q'k' = 0$. If, therefore, we further suppose $k = 0$, or that the origin of the co-ordinates is placed at S, we shall also have $p' = 0$, $q' = 0$, whence the pivot T sustains no pressure, the whole being exerted on S.

If OZ, besides being a principal axis, also passes through the centre of gravity, then $x_1 = 0$, $y_1 = 0$, whence $p + p' = 0$, $q + q' = 0$; and since p' and q' vanish when OZ is a principal axis, therefore $p = 0$, $q = 0$, so that no pressure is exerted on either of the pivots; and if they were removed, the body would still continue to revolve about the same axis.

The forces thus determined are in some sort the inverse of those arising from the percussions found in (29), the values of $p + p'$ being in this case expressed in terms of x, and in the former in terms of y; and the value of $q + q'$, which in the case of the percussions was expressed in terms of x, is here given in terms of y.

Centre
gyratio

39. In computing the effect of machines, it is often convenient to determine the situation of a point in which the whole mass of the machine might be concentrated without altering the rotatory effort. In the straight line OG (fig. 8) suppose a point Q to be taken, such that $OQ^2 = \int r^2dm =$ moment of inertia in respect of the axis O; then, if the whole matter in the body were collected at Q, a force applied at any point P in the line OG, would produce exactly the same angular velocity as if applied to the same point of the body having its natural form. For if the whole mass M were concentrated at Q, the moment of inertia would become $M{\cdot}OQ^2$ (13), and the moment of the force F applied at P is $F{\cdot}OP$; therefore the angular velocity (14) would be $\frac{F{\cdot}OP}{M{\cdot}OQ^2}$. But the angular velocity produced by the force F applied at P, the body having its natural form, is $\frac{F{\cdot}OP}{\int r^2dm}$; therefore, since $M{\cdot}OQ^2 = \int r^2dm$, the two expressions are equal, and the angular velocity is not altered by supposing the whole mass concentrated at Q.

40. The point Q is called the *centre of gyration* of the revolving mass; and since $OQ = \sqrt{\int r^2dm \div M}$, its distance from the axis O is found by extracting the square root of the quotient which is obtained by dividing the moment of inertia by the mass of the body. It is also connected with the centres of gravity and percussion by a simple relation. Suppose P to be the centre of percussion, then (34) $OP = \int r^2dm \div M \cdot OG$, therefore $OG \cdot OP = \int r^2dm \div M = OQ^2$; whence the distance of the centre of gyration from the axis of rotation is a mean proportional between the distances of the centre of gravity and percussion from the axis.

In a straight line or slender rod, as a working beam, or the spoke of a wheel in a machine, OQ is $\sqrt{\frac{1}{3}}$ of its length; for in this case $\int r^2dm = \int r^2dr = \frac{1}{3}r^2$; and r being the whole length, $M = r$; therefore $\sqrt{\int r^2dm \div M} = r\sqrt{\frac{1}{3}}$.

In a circle or cylinder turning about its axis, $\mathrm{OQ} = \sqrt{\frac{1}{2}}$ the radius; for by (18) we have in this case $\int r^2 dm = \frac{1}{2}\mathrm{M}r^2$; therefore $\sqrt{\int r^2 dm} \div \mathrm{M} = r\sqrt{\frac{1}{2}}$. But if the circle turns round one of its diameters, then $\mathrm{OQ} = \frac{1}{2}$ the radius; for in this case $\int r^2 dm = \frac{1}{4}\mathrm{M}\,r^2$; therefore $\sqrt{\int r^2 dm \div \mathrm{M}} = \frac{1}{2}r$.

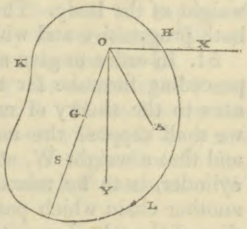
In the periphery of a circle, or rim of a wheel, turning about a diameter perpendicular to its plane, $\mathrm{OQ} =$ radius; for $\int r^2 dm = r^2 \times 2\pi r = 2\pi r^3$, and $\mathrm{M} = 2\pi r$; therefore $\sqrt{\int r^2 dm \div \mathrm{M}} = r$.

A solid sphere turning round a diameter has $\mathrm{OQ} = r\sqrt{\frac{2}{5}}$ for (18) the moment of inertia of the sphere is $\frac{8}{15}\pi r^5$; and the mass $\mathrm{M} = \frac{4}{3}\pi r^3$; therefore $\mathrm{OQ} = \sqrt{\frac{6}{15}r^2} = r\sqrt{\frac{2}{5}}$.

Fo ulæ for ccele- rat for s.

41. In what precedes, we have supposed that the force applied to a rigid system produces its effect by instantaneous impact, and then ceases to act, so that the motion communicated to the system is uniform. But if the action of the external force continues after the first impact, like the force of gravity on a falling body, the motion of the system will be accelerated. In the case of uniform velocity, it has been shown (14) that the angular velocity is equal to the moment of the applied force divided by the moment of inertia; that is, assuming F to denote the force, and P the perpendicular from the axis on the line of its direction, $w = p\cdot\mathrm{F} \div \int r^2 dm$. Suppose now the body to be subjected to the action of an accelerating force, and let dw be the increment of the angular velocity in the very small time dt. The increment of the actual velocity of the particle dm, the distance of which from the axis is r, is then rdw, and its accelerating force (the ratio of the increment of the velocity to the increment of the time) is $r\frac{dw}{dt}$. Its moving force is consequently $\frac{dw}{dt}\cdot rdm$; and since the direction of this force is perpendicular to r, its moment $= \frac{dw}{dt}\cdot r^2 dm$. But the sum of all these moments, in respect of every particle dm, must be equal to the moment of the impressed force, continuing to act during the same instant of time, therefore $\frac{dw}{dt}\int r^2 dm = p\cdot\mathrm{F}$, whence $\frac{dw}{dt} = \frac{p\cdot\mathrm{F}}{\int r^2 dm}$.

Fig. 9.



42. In the case of a heavy body oscillating about an axis by the force of gravity, let HKL be a section of the body passing through the centre of gravity G, and let the axis of suspension be at O, and perpendicular to the plane HKL. Also, let OX be horizontal, and OY vertical. Then the accelerating force being denoted by g ($g = 32$ feet in a second of time), the moving force in respect of a particle dm at A is gdm; and the direction of this force being parallel to OY, the distance of its direction from the axis is x; therefore its moment $= gxdm$. The sum of all these moments is the moment of the whole gravitating force of the body, that is, $g\int xdm = p\cdot\mathrm{F}$, and we have consequently, since $\int xdm = \mathrm{M}x_1$,

$$\frac{dw}{dt}\int r^2 dm = g\,\mathrm{M}x_1,\ \text{whence}\ \frac{dw}{dt} = \frac{g\mathrm{M}x_1}{\int r^2 dm}.$$

When the centre of gravity is in the straight line OY, or in the vertical passing through the axis, then $x_1 = 0$, and the angular velocity is uniform, and the body, if it rest in that position, would have no tendency to turn. But suppose the centre of gravity to be drawn aside from the vertical, and let $\mathrm{OG} = k$, and the angle $\mathrm{GOY} = \theta$, then $x_1 = k \sin.\theta$, and we have

$$\frac{dw}{dt} = \frac{g\mathrm{M}k\sin.\theta}{\int r^2 dm.},$$

whence the acceleration of the angular velocity is proportional to the sine of the angle which the line OG makes with the vertical.

43. Suppose the whole mass of the body to be concentrated at a point S in the straight line OG; we shall then have $r = \mathrm{OS}$, $\int r^2 dm = \mathrm{M}\cdot\mathrm{OS}^2$, and the formula will become $\frac{dw}{dt} = \frac{g\sin.\theta}{\mathrm{OS}}$. Now, if the point S be chosen such that $\mathrm{OS} = \int r^2 dm \div \mathrm{M}\cdot k$, then the two formulæ will be identical, and the solid body will oscillate exactly in the same time as if all its matter were united at the point S, and connected with the axis by an inflexible rod without weight, that is, in the same time as a simple pendulum, of which the length is OS.

Since $r^2 = x^2 + y^2$, and $\mathrm{M}\cdot k = \int xdm$, this expression for OS may be put under the following form, in which it is usually exhibited, namely,

$$\mathrm{OS} = \frac{\int(x^2 + y^2)\,dm}{\int xdm}.$$

Centre of oscillation.

44. The point S is called the *centre of oscillation.* On comparing the expression for OS with that for OP in (34), it will be seen that it is at the same distance from the axis as the centre of percussion. But the centre of oscillation is not, strictly speaking, limited to a single point; for it through S a line be drawn perpendicular to the plane HKL, or parallel to the axis of rotation, every point in this line will move with the same angular velocity as if it were entirely unconnected with the other points of the oscillating body, and the line itself is denominated the *axis of oscillation.* It is usual, however, to understand by the term *centre of oscillation*, the point S which is situated in the straight line, perpendicular to the axis, which contains the centre of gravity.

45. If we denote the moment of inertia of the body in respect of the axis which passes through G the centre of gravity, perpendicular to the plane HKL, by $\mathrm{M}\cdot h^2$, then h is a given line; and if we also make $\mathrm{OG} = k$, then (17) the moment of inertia in respect of the axis passing through O is $\mathrm{M}(h^2 + k^2)$. Hence we find $\mathrm{OS} = \frac{\mathrm{M}(h^2 + k^2)}{\mathrm{M}\cdot k} = k + \frac{h^2}{k}$; and consequently $\mathrm{GS} = \frac{h^2}{k}$. This formula gives the distance of the centre of oscillation below the centre of gravity.

46. The point S possesses several very remarkable properties, one of which is, that as S is the centre of oscillation of the body turning about O, so O is the centre of oscillation of the body turning about the parallel axis passing through S; in other words, the centres of oscillation and suspension are convertible. For it has been shown (45) that $\mathrm{GS} = \frac{h^2}{k} = \frac{h^2}{\mathrm{OG}}$; therefore $\mathrm{OG} = \frac{h^2}{\mathrm{GS}}$, that is to say, if the body oscillates about the axis passing through S, then O is the centre of oscillation. This curious property, which was first demonstrated by Huygens in his *Horologium Oscillatorium*, was ingeniously applied by Captain Kater as a practical means of determining the length of the seconds pendulum. Two axes being assumed in a bar or rod of metal, the bar is adjusted by filing away one of its ends until the oscillations about each axis are performed exactly in the same time; and when this equality has been established, the distance between the axes is the length of the synchronous simple pendulum. See PENDULUM.

47. We shall now determine the centre of oscillation in a few particular cases.

Computation of centres of oscillation.

If the body is a heavy straight line suspended by one extremity, the OS $= \frac{2}{3}$ of its length; for making $a =$ the length of the rod, we have (18) $\int r^2 dm = \frac{1}{3} a^3$, and in this case the mass $M = a$, and the centre of gravity is at the middle of the line, or $k = \frac{1}{2}a$, whence $Mk = \frac{1}{2}a^2$, and OS $= \int r^2 dm \div Mk = \frac{1}{3}a^3 \div \frac{1}{2}a^2 = \frac{2}{3}a$.

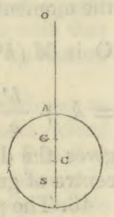
This is nearly the case of a slender rod of a cylindrical or prismatic shape, and it would be accurately so if all the points of a transverse section were equally distant from the axis of suspension.

If the oscillating body is an isosceles triangle suspended by its apex, and vibrating perpendicularly to its plane, O $= \frac{3}{4}$ of its height. For let $a =$ the height, $na =$ the base, $y =$ a section parallel to the base, then $y = nx$, $r = x$, and $dm = ydx$; whence $\int r^2 dm = n\int x^3 dx = \frac{1}{4}na^4$ (when $x = a$), But in this case $M =$ area $= \frac{1}{2} a \times na = \frac{1}{2} na^2$; and the distance of the centre of gravity from the vertex being two thirds of the height, we have $k = \frac{2}{3}a$, whence $Mk = \frac{1}{3} na^3$, and consequently OS $= \int r^2 dm \div Mk = \frac{3}{4}a$.

48. The problem to find the centre of oscillation of a sphere suspended by a thread or an inflexible rod, is important on account of its application to the measurement of the seconds pendulum. Let us first suppose that the weight of the thread is insensible in comparison of that of the ball. Let $r =$ radius of ball, $l =$ length of thread from the point of suspension to the ball, and $a = l + r =$ distance from the point of suspension to the centre of the ball. The moment of inertia of the sphere in respect of an axis passing through its centre (18) is $\frac{2}{5}Mr^2$; therefore (17) the moment in respect of a parallel axis at the distance a is $M(a^2 + \frac{2}{5}r^2)$; and on dividing this by $Mk (= Ma)$, we get the distance from the point of suspension to the centre of oscillation $= a + \frac{2r^2}{5a}$, or the centre of oscillation is below the centre of gravity by the distance $\frac{2}{5}r^2 \div a$.

49. Let us now suppose the weight of the thread or rod to be taken into account. Let C (fig. 10) be the centre of the ball, G the centre of gravity of the ball and rod OA, S the centre of oscillation; also let $b =$ weight of ball, and $b' =$ weight of rod. The moment of the sphere, oscillating about O, supposing the weight of the rod insensible, is found above $= M(a^2 + \frac{2}{5}r^2)$; and (18) the moment of the rod alone is $\frac{1}{3}OA^3 = \frac{1}{3}l^3 = \frac{1}{3}M'l^2$ (putting $M' =$ mass of the rod); therefore, substituting the weights for the masses, that is, making $M = b$, and $M' = b'$, the moment of the compound body is $b(a^2 + \frac{2}{5}r^2) + \frac{1}{3}b'l^2$. Now, to find the position of G the centre of gravity, we have this theorem in statics, that the product of the whole mass multiplied into the distance of its centre of gravity from the axis, is equal to the sum of the products of the masses of the several parts into the respective distances of their centres of gravity; that is, putting OG $= k$, we have $(M + M')k = ba + \frac{1}{2}b'l$, and consequently (45),

Fig. 10.



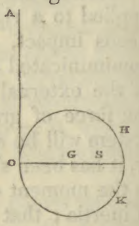
$$OS = \frac{b(a^2 + \frac{2}{5}r^2) + \frac{1}{3}b'l^2}{ba + \frac{1}{2}b'l}.$$

Rotation on inclined planes.

50. Hitherto we have supposed the axes of rotation to be absolutely fixed; but the rotation may be performed about axes which are themselves in motion, as in the case of a ball or cylinder rolling down an inclined plane. When a ball rolls down an inclined plane, the point of the ball which rests on the plane is hindered from sliding down by friction; and therefore the ball tumbles, as it were, over this point of contact, and is instantly caught by another point of contact, over which it tumbles in the same manner. A cylinder rolls down in the very same way; and its motion is nearly the same as if a fine thread had been lapped round it, and one end of it made fast at the head of the inclined plane. The cylinder rolls down by unwinding this thread.

The mechanism of all such motions (and some of them are important) may be understood by considering them as follows: Let a body of any shape be connected with a cylinder HOK (fig. 11), whose axis passes through G, the centre of gravity of the body. Suppose the body suspended from a fixed point A by a thread wound round the cylinder. The body will descend by the action of gravity, and it will also turn round, unwinding the thread. Draw the horizontal line SGO; this will pass through the point of contact O of the thread and cylinder, and O is the point round which the cylinder *begins* to turn in descending. Let S be its centre of oscillation corresponding to the momentary centre of rotation O. The body will begin to descend in the same manner as if all its matter were collected in S; for it may be considered, in this instant, as a pendulum suspended at O. But in this case S will descend in the same manner as if the body were falling freely. Therefore the velocity of G (that is, the velocity of descent) will be to the velocity with which a heavy body would fall as OG to OS. Now since the points O, G, S, are always in a horizontal line, and the radius OG is given, as also OS (43), the velocity of a body falling freely, and of the body unwinding from this thread, will always be in the same proportion of OS to OG, and so will the spaces described in any given time. And thus we can compare their motions in every case when we know the place of the centre of oscillation.

Fig. 11.



It follows from this that the weight of the descending body will be to the tension of the thread as OS to GS; for the tension of the thread is the difference between the moment of the rolling body and that of the body falling freely. It is to be remarked, that this proportion between the weight of the body and the tension of the thread will be always the same; for it has been demonstrated (46), that if O be in the circumference of a circle whose centre is G, S will be in the circumference of another circle round the same centre, and therefore the ratio of OG to OS is constant.

If a circular body HOK roll down an inclined plane by unfolding a thread, or by friction which prevents all sliding, the space described will be to that which the body would describe freely as OG to OS; for the tendency down the inclined plane is a determined proportion of the weight of the body. The motion of rotation in these cases, both progressive and whirling, is uniformly accelerated.

Inertia of machines.

51. In order to give an example of the application of the preceding formulæ for the rotation of bodies about fixed axes to the theory of machines actually performing work, we shall suppose the machine to be the wheel and axle, and that a weight W, attached to a chain passing over the cylinder, is to be raised by means of a power acting on another chain which passes over the wheel. Let the radius of the wheel $= a$, the radius of the cylinder $= b$, and suppose the moving power to be another weight P, or a mass of matter descending by the accelerating force of gravity.

Since the machine is in this case impelled by an accelerating force, the angular velocity w is obtained from the equation (41), namely,

$$\frac{dw}{dt} = \frac{\text{moment of impelling force}}{\text{moment of inertia}}.$$

Now, because the weight P acts in a straight line whose distance from the axis $= a$, the moment of its force is Pa; and in like manner the moment of the force exerted by W is Wb. But this last moment retards the motion, and must be taken as negative; therefore the moment of the impelling force is $Pa - Wb$. Again, the moment of inertia is made up of three parts: first, the moment of inertia of the machine, which depends on the quantity of dead matter contained in the wheel and cylinder, and which we may denote by K; second, the moment of inertia of the weight P, which may be considered as attached to the extremity of the radius of the wheel; third, the moment of inertia of the weight W, which may be considered as attached to the extremity of the radius of the cylinder. Let M and M′ be the masses of the bodies whose weights are P and W, then the moments of inertia are respectively Ma^2 and $M'b^2$. Let also $g =$ the acceleration of gravity, then the weight of a body being the product of its mass into the force of gravity, we have $P = gM$, $W = gM'$, whence the whole moment of inertia is

$$K + \frac{Pa^2}{g} + \frac{Wb^2}{g},$$

and we have consequently

$$\frac{dw}{dt} = \frac{g\,(Pa - Wb)}{gK + Pa^2 + Wb^2}.$$

For the sake of abridging, let us assume $U = \frac{Pa - Wb}{gK + Pa^2 + Wb^2}$, and the angular velocity will be given by the equation $w = g\int U dt$. Also let $v =$ the velocity of the *impelled point* of the machine, or the velocity with which P descends, and $u =$ the velocity of the *working point*, or velocity with which W is raised; then $v = aw$, and $u = bw$, at the end of the time t; and if we denote the respective accelerating forces by φ and ψ, we shall have

$$\varphi = \frac{dv}{dt} = agU,\ \psi = \frac{du}{dt} = bgU.$$

52. To find the proportion of the velocities of the impelled and working points which give the greatest performance when the weight and power are both given, we may treat the formula which expresses the work, that is, the accelerating force, or W, as a fluxionary quantity, and find its maximum. Thus, to find the radius of the wheel by which the weight will be raised with the greatest velocity, we have to differentiate the quantity denoted by U, on the supposition that a is variable, and make the result equal to zero. This will give an equation from which a will be obtained in terms of P, W, and b; and it will be observed, that as K varies with a, the value of K in terms of a must be substituted in the value of U before the differentiation.

53. The friction may be taken account of by considering it as a quantity to be added to the weight W. Let $f =$ the co-efficient of friction, and $c =$ radius of the pivots supporting the machine, then the friction will be expressed by $fc\,(P + W)$, and we have only to substitute $Wb + fc\,(P + W)$ for Wb in the above expression for U.

54. In the case of the fixed pulley, the velocities of P and W are equal, and we have also $a = b$. If we denote the weight of the pulley by Q, then its mass will be $Q \div g$, and (18) its moment of inertia $= \frac{1}{2}\,Qa^2 \div g$; therefore the formula for the accelerating force with which P descends or W rises will be

$$\varphi = g \cdot \frac{P - W}{\frac{1}{2}\,Q + P + W}.$$

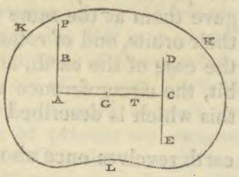
Mot of a solid ody enti y free.

55. We now proceed to consider the motion of a solid body which is entirely free.

When a solid body or rigid system is impressed at a single point by a force of which the direction does not pass through the centre of gravity, the body, if free to move in every direction, acquires two motions, one progressive, and equal to that which would have resulted if the direction of the force had passed through the centre of gravity, and the other rotatory, and equal to that which would have resulted if the body had been only at liberty to move round a fixed axis passing through the centre of gravity, and perpendicular to the plane which contains that centre, and the line of the direction of the impelling force.

56. In order to demonstrate this proposition, let HKL (fig. 12) be a section of the body passing through G the centre of gravity, and containing the line in which the force is directed; let P be the point at which the given force F is applied, and PA its direction; through G draw GA perpendicular to PA, and let PA represent the intensity of the force F. Bisect AP in B, produce AG until $GC = AG$, and through C draw CD, CE perpendicular to AC, and make each equal to AB. If we now conceive a force represented by DC to be applied at D in the direction DC, and another force represented by EC to be applied at E in the direction EC, these two forces being equal, and acting in opposite directions, will destroy each other, or produce no movement in the body, and the motion which actually takes place in consequence of the application of the force PA at P, will be the same as would result from the application of the four forces PB, BA, DC, EC. Now it is evident, that if the two forces BA and DC acted alone, they would produce no rotatory motion about the axis passing through G, for their moments $BA \cdot AG$ and $DC \cdot CG$ are equal, and they tend to turn the body in opposite directions. But the same two forces both tend to give the body a progressive motion; and as the resultant of two equal and parallel forces is a force equal to their sum, and acting at the point which bisects the distance between their directions, the initial progressive motion of the body in consequence of the forces BA and DC will be the same as if the force $PA = F$ were applied at the point G in the direction parallel to PA. We have now to consider the two remaining forces PB and EC. As these two forces act on the line AC in opposite directions, their resultant is nothing, or their separate tendencies to produce a progressive motion in the centre of gravity of the body, are counteracted by their joint effort. But they conspire in tending to produce a rotatory motion in the same direction about the axis passing through G; and the moment of the first in respect of that axis being $PB \cdot AG$, and that of the second $EC \cdot CG$, the sum of their moments is $(PB + EC)\,AG$ or $PA \cdot AG$. The whole effect of these two forces is therefore to produce the same initial angular velocity about the axis through G, perpendicular to HKL, as would be produced by the single force PA applied at the point A; and it has been shown, that the whole effect of the forces BA and DC is to produce the same progressive movement of the centre of gravity as if the single force PA were applied at that point, consequently the proposition is demonstrated, and it appears that the two motions produced by the application of a force which is not directed towards the centre of gravity may be considered independently of each other.

Fig. 12.



57. Let $V =$ the progressive velocity of the centre of gravity in the direction parallel to PA; then the mass of the body being M, we have the force $F = MV$, and consequently $V = F \div M$. Again, if we make $AG = l$, the angular velocity produced by the force F applied at A is $w = F \cdot l \div \int r^2 dm$ (14), therefore $V : w :: \int r^2 dm : Ml$. Now, since $\int r^2 dm$ and M are both known from the nature of the body, it follows, that when the distance l is given, the ratio of the progressive motion of the centre of gravity to the velocity of angular rotation can be found; and, conversely, when the ratio of the two velocities is given, the distance l can be found. For example, let s be the space described by the centre of gravity while the body makes one revolution about its axis, then 2π is the space described, in consequence of the rotatory motion, by a point of the body whose distance from the axis $= 1$, and the above proportion gives $l = \frac{2\pi}{s} \cdot \frac{\int r^2 dm}{M}$.

58. As it is not necessary that the progressive motion of the centre of gravity be in a straight line, this formula enables us to determine the distances from the centre at which the planets may have received the single impulses which gave them at the same time their motions of revolution in their orbits, and of rotation round their axes. Thus, taking the case of the earth, and making R = the radius of its orbit, the circumference of the orbit is $2\pi R$, and the part of this which is described by the centre of gravity, while the earth revolves once about its axis, is $\frac{2\pi R}{365} = s$; and by (18) $\int r^2 dm \div M = \frac{2}{5} r^2$; therefore $l = \frac{365 \times 2r^2}{5R}$. If we assume $r = 4000$ miles, and $R = 95{,}000{,}000$ miles, this formula gives $l = 24\frac{1}{2}$ miles nearly.

Centre of spontaneous rotation.

59. The direction of the force being PA (fig. 12), if a point be taken in the line AG between A and G, the motion of the point arising from the rotation of the body about the axis is in the first instant of time parallel to the direction of the progressive motion, and if r be its distance from G, the velocity due to both motions will be $V + rw$. But if the point be taken on the other side of G, the direction of the rotatory motion will be opposite to that of the progressive motion, and the velocity of the point will be $V - rw$. If therefore the point T be taken such that making $GT = r$, we have the equation $V = rw$; then, for a single instant, every point in the straight line passing through T perpendicular to HKL is at rest, or is carried as far back by the rotatory motion in the first instant of time, as it is carried forward by the progressive motion; and, for a single instant, the double motion of the body may be regarded as a simple rotatory motion about that straight line. This point T is called the *centre of spontaneous rotation*, and the straight line passing through T, perpendicular to the plane HKL, is called the *axis of spontaneous rotation*.

Progressive motion of centre of gravity.

60. The preceding formulæ enable us to determine completely the two motions of translation and rotation when a force is applied to a single point of the free body; we have now to determine what the effect will be when any number of forces given in magnitude and direction are applied to different points of the body; and as it appears from what precedes, that during the first instant the two motions take place independently of each other, we shall first give the equations which fix the position of the centre of gravity of the moving body, and then those which define the rotatory motion, or determine the position of any point of the body with reference to its centre of gravity.

Let G be the centre of gravity of the body, M its mass, and let the motion be referred to three rectangular axes OX, OY, OZ. Let us now suppose forces given in magnitude and direction to be applied at the points A, A′, A″, &c. of the body, and that each of them is resolved into three others respectively parallel to the directions of the axis, and let p, q, r, be the resolved forces applied at A; p', q', r', the resolved forces applied at A′, and so on; also let $P = p + p' + p'' +$, &c., $Q = q + q' + q'' +$, &c., $R = r + r' + r'' +$, &c.; then, since the moving force is equal to the product of the mass into the velocity, and since by (56) the progressive motion resulting from the force applied at A is the same as if it had been applied to the centre of gravity, the velocity of the centre of gravity from the joint action of all the forces, in the directions OX, OY, OZ, will be respectively $\frac{P}{M}$, $\frac{Q}{M}$, $\frac{R}{M}$. But the resulting velocity is the diagonal of the parallelopiped of which these component velocities are the sides; therefore, denoting it by V, we have

$$V = \frac{1}{M}\sqrt{(P^2 + Q^2 + R^2)}.$$

To determine the direction of this velocity, let α, β, γ, be the angles which its direction makes with the axis x, y, z; then, since the forces P, Q, R meet in a point (the centre of gravity), we have

$$\cos.\ \alpha = \frac{P}{MV},\ \cos.\ \beta = \frac{Q}{MV},\ \cos.\ \gamma = \frac{R}{MV}.$$

These equations give the direction of the velocity; hence, since V has already been found, the initial velocity of the centre of gravity and its direction are both completely determined.

61. When the forces applied to the body are simply percussions, which cease to act after the first impact, and there is no resistance, no change will take place in the velocity or its direction during the second and succeeding instants, and the centre of gravity will describe a straight line with a uniform motion; but if the forces continue to act after the motion has commenced, we must have recourse to the formulæ given by the principles of dynamics, which express the varied motion of a body subjected to the action of accelerating forces. At the end of the time t, reckoned from the commencement of the motion, let x, y, z be the co-ordinates of the element of the body dm, referred to the rectangular axes OX, OY, OZ; then the velocity at that instant being expressed by the differential of the space described divided by the element of the time, the components of the velocity at the same instant will be $\frac{dx}{dt}$, $\frac{dy}{dt}$, $\frac{dz}{dt}$. Now the forces acting on the body, whatever be their nature, may always be decomposed into others parallel to the three axes; suppose therefore P, Q, R to be the components of the accelerating forces in those directions acting on the point dm, then the increment of velocity being equal to the force into the element of the time, if the particle dm were entirely free, the velocities $\frac{dx}{dt}$, $\frac{dy}{dt}$, $\frac{dz}{dt}$ would acquire the increments Pdt, Qdt, Rdt in the instant dt. But the increments of velocity actually acquired in the instant dt are the differentials of the velocities, or $d \cdot \frac{dx}{dt}$, $d \cdot \frac{dy}{dt}$, $d \cdot \frac{dz}{dt}$, and therefore the velocities lost in consequence of the mutual connection of the particles are respectively

$$Pdt - d \cdot \frac{dx}{dt},\ Qdt - d \cdot \frac{dy}{dt},\ Rdt - d \cdot \frac{dz}{dt}.$$

Multiplying each of these expressions by dm, we get the quantities of motion due to the respective velocities. Now, according to a well-known principle of dynamics, the discovery of which is due to D'Alembert, the infinitely small quantities of motion lost in every instant by all the particles in consequence of their mutual connection must make equilibrium; the integrals of the preceding expressions multiplied by dm must therefore be severally equal to zero, and we have accordingly (on effecting the operations indicated, and dividing by dt) the three equations

$$\int P dm = \int \frac{d^2x}{dt^2} dm,\ \int Q dm = \int \frac{d^2y}{dt^2} dm,\ \int R dm = \int \frac{d^2z}{dt^2} dm.$$

62. In order to find the place of the centre of gravity at the end of the time t, let its co-ordinates at that instant be x_1, y_1, z_1; then from the property of the centre of gravity we have

$$Mx_1 = \int x dm,\ My_1 = \int y dm,\ Mz_1 = \int z dm.$$

Regarding the variables as functions of the time t, differentiating twice, and dividing each time by dt, we obtain

$$M\frac{d^2x_1}{dt^2} = \int \frac{d^2x}{dt} dm,\ M\frac{d^2y_1}{dt^2} = \int \frac{d^2y}{dt^2} dm,$$

$$M\frac{d^2z_1}{dt^2} = \int \frac{d^2z}{dt^2} dm.$$

Comparing these with the above equations, we have

$$\mathrm{M}\frac{d^2x_1}{dt^2}=\int \mathrm{P}dm,\ \mathrm{M}\frac{d^2y_1}{dt^2}=\int \mathrm{Q}dm,\ \mathrm{M}\frac{d^2z_1}{dt^2}=\int \mathrm{R}dm.$$

Now, the first members of these equations denote respectively the quantities of motion in the direction of the axes x, y, z, of a material point whose mass $=$ M, and the integrals $\int \mathrm{P}dm$, $\int \mathrm{Q}dm$, $\int \mathrm{R}dm$ denote the quantities of motion of the body or rigid system under consideration, subjected to the accelerating forces P, Q, R; it follows, therefore, that during the whole continuance of the motion the centre of gravity moves as if the whole of the matter of the body were concentrated there, and the forces which act on the body were all applied at that point.

63. Having thus given the equations which enable us to determine the motion of the centre of gravity of a free system under the action of given forces, we now proceed to consider the rotatory movement of the system, and to investigate the position of any point of it with respect to the centre of gravity at the end of any given interval of time. The investigation of this problem is greatly facilitated by means of the following elegant theorem respecting the composition of rotatory motion, discovered by Frisi.

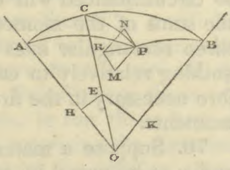
Composition of rotatory motion.

Proposition. If a solid body revolve round an axis OA (fig. 13) passing through its centre of gravity with an angular velocity $= w$, and if a force be impressed upon it which alone would cause it to revolve about an axis OB also passing through its centre of gravity with an angular velocity $= w'$, then the body will not revolve about either OA or OB, but about a third axis OC lying in the plane of the other two, and inclined to each of the former axes in angles whose sines are inversely as the angular velocities round those axes, or so that sin. AOC : sin. BOC :: $w' : w$; and the angular velocity u round the new axis is to that round one of the primitive axes as the sine of inclination of the two primitive axes is to the sine of the inclination of the new axis to the other primitive axis, that is, $u : w$ :: sin. AOB : sin. COB, or $u : w'$ :: sin. AOB : sin. AOC.

64. In order to prove this proposition, it is necessary to show, 1st, that any point in the line OC is at rest while the two motions are taking place; 2d, that every particle of the body not situated in AC revolves about the axis AC; and 3d, to assign the velocity of rotation.

(1.) Let the angular motion about the axis OA be supposed to be in the direction by which every point in the angle AOB would be raised above the plane of the paper, and that about OB to be in the direction by which every point within the same angle would be depressed below the plane of the paper, and take any point E in OC, and draw EH and EK respectively perpendicular to OA and OB. The absolute velocity with which the point E moves in consequence of the rotation about OA is HE $\cdot w$, and the absolute velocity with which it moves about OB is KE $\cdot w'$. But HF $=$ OE sin. AOC, and KE $=$ OE sin. BOC; and by hypothesis $w' : w$ :: sin. AOC : sin. BOC, whence w' sin. BOC $= w$ sin. AOC, therefore the two velocities HE $\cdot w$ and KE $\cdot w'$ are equal; and they are in opposite directions, consequently the point E remains at rest. In the same manner, it is shown that every other point in OC remains at rest.

Fig. 13.



(2.) Let P be the place of any particle of the body, and conceive the surface of a sphere to pass through P, intersecting the axes in A and B, and join PA and PB by arcs of great circles. Draw PM perpendicular to AP, and make PM $= w \cdot$ sin. AP $=$ absolute velocity of the particle P about the axis OA in 1″ of time; also draw PN perpendicular to BP, and make PN $= w' \cdot$ sin. BP $=$ absolute velocity of P about OB in 1″ (the radius being unity), and complete the parallelogram PMRN.

Since the particle dm, in virtue of the rotation about OA, has a motion which would cause it to describe the line PM in a second, and in virtue of the rotation about OB has also a motion which would cause it to describe PN in a second, the particle will describe PR the diagonal of the parallelogram PMRN. Through P let an arc of a great circle be described perpendicular to PR, and produced to meet the plane AOB in the point C, which at present we suppose indeterminate, and join OC; then OC is the straight line in which a plane passing through P, perpendicular to PR, intersects the plane AOB.

Because APM and CPR are equal, being right angles, take from each the common angle APR, and there remains RPM $=$ APC; and because BPN and CPR are right angles, add to each NPC, and we have RPN $=$ BPC. Now PM $= w$ sin. AP, and PN $=$ RM $= w' \cdot$ sin. BP, therefore

PM : RM :: w sin. AP : w' sin. BP;

but PM : RM :: sin. MRP ($=$ sin. RPN) : sin. RPM,

or PM : RM :: sin. BPC : sin. APC;

therefore sin. BPC : sin. APC :: w sin. AP : w' sin. BP,

whence w' sin. BP $\cdot$ sin. BPC $= w$ sin. AP $\cdot$ sin. APC.

Now in the spherical triangles BPC and APC we have sin BP $\cdot$ sin. BPC $=$ sin. CB $\cdot$ sin. PCB, and sin. AP $\cdot$ sin. APC $=$ sin. AC $\cdot$ sin. ACP; therefore

w' sin. CB $\cdot$ PCB $= w$ sin. AC $\cdot$ sin. ACP.

But sin. PCB $=$ sin. ACP (the one angle being the supplement of the other); also sin. CB $=$ sin. BOC, sin. AC $=$ sin. AOC, therefore w' sin. BOC $= w$ sin. AOC, and consequently

$w : w'$ :: sin. BOC : sin. AOC.

From this it follows that OC divides the angle AOB into parts having a given ratio, and is therefore given in position; and as it may be shown in like manner that the plane passing through every other particle of the body perpendicular to the direction of the motion of that point intersects the plane AOB in OC, OC is therefore the axis of rotation.

(3.) To find u, the angular velocity about OC. In the triangle RPM we have RP : PM :: sin. RMP : sin. MRP; but sin. RMP $=$ sin. MPN $=$ sin. APB, and sin. MRP $=$ sin. RPN $=$ sin. CPB, therefore RP : PM :: sin. APB : sin. CPD. Now RP $= u$ sin. CP $=$ absolute velocity about OC in 1″, and PM $= w$ sin. AP $=$ absolute velocity about OA in 1″. Substituting these expressions therefore in the last proportion, and multiplying extremes and means, we get

u sin. CP $\cdot$ sin. CPB $= w$ sin. AP $\cdot$ sin. APB.

But the spherical triangles CPB and APB give sin. CP sin. CPB $=$ sin. CB sin. CBP, and sin. AP sin. APB $=$ sin. AB sin. ABP. Therefore, substituting, and leaving out the common term, we have u sin. CB $= w$ sin. AB, or u sin. COB $= w$ sin. AOB, that is,

$u : w$ :: sin. AOB : sin. COB.

In like manner, it may be shown that

$u : w'$ :: sin. AOB : sin. AOC,

whence the proposition is demonstrated.

65. When the two primitive axes OA and OB are at right angles, sin. AOB $= 1$, sin. COB $=$ cos. AOC, and the above two proportions give $u : w :: 1 :$ cos. AOC, $u : w' :: 1 :$ sin. AOC, whence u cos. AOC $= w$, and u sin. AOC $= w'$, and consequently $u^2 = w^2 + w'^2$, or $u = \sqrt{(w^2 + w'^2)}$.

66. Suppose a third axis OD at right angles to OA and OB, and that a force is impressed on the body, which alone would cause it to revolve about OD with an angular velocity $= w''$; then, as the body is revolving about OC with the velocity u, the effect of this new force will be to cause it to revolve about an axis in the plane DOC; and if we make $\psi =$ the angle which this new axis makes with the line OC, and W $=$ the velocity about the new axis, we

shall have from the preceding formulæ W cos. $\psi = u$, and W sin. $\psi = w''$, whence $W = \sqrt{(u^2 + w''^2)}$, or, substituting for u its value found above, $W = \sqrt{(w^2 + w'^2 + w''^2)}$. The position of the new axis is, however, more conveniently defined by the angles which it makes with the three primitive axes. Let α, β, γ be the angles which it makes respectively with the primitive axes OA, OB, OD, then the three spherical triangles which it forms with the three axes give cos. α = cos. AOC cos. ψ, cos. β = cos. BOC cos. ψ, cos. γ = sin. ψ. Now, from the preceding equations (65), we have

$$\text{cos. AOC} = \frac{w}{u}, \text{cos. BOC} = \text{sin. AOC} = \frac{w'}{u}, \text{cos.}\,\psi = \frac{u}{W},$$

$$\text{sin.}\,\psi = \frac{w''}{W}.$$ Therefore, substituting and writing for W its value $\sqrt{(w^2 + w'^2 + w''^2)}$, we obtain

$$\text{cos.}\,\alpha = \frac{w}{\sqrt{(w^2 + w'^2 + w''^2)}}, \text{cos.}\,\beta = \frac{w'}{\sqrt{(w + w'^2 + w''^2)}},$$

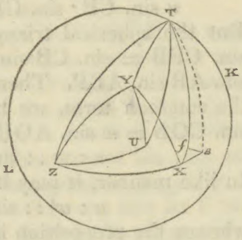
$$\text{cos.}\,\gamma = \frac{w''}{\sqrt{(w + w'^2 + w''^2)}}.$$

Hence it follows that the change of position of any point in consequence of the rotation W*dt*, in the element of time *dt*, is equivalent to the change that would be effected by three simultaneous and independent rotations W*dt* cos. α, W*dt* cos. β, W*dt* cos. γ, about three rectangular axes, with which the axis corresponding to the velocity W makes respectively the angles α, β, γ.

67. In determining the rotation of a body about a fixed centre, it is most convenient to refer every point of the body to a system of three principal axes passing through the centre of gravity; there are therefore two distinct steps in the investigation, the first being to find the situation of the principal axes in respect of absolute space at the end of any given time, and the second to find the position of any point of the body referred to these axes, whose positions have been determined. To accomplish the first of these, the following proposition is required.

68. If at the end of any time *t* the position of the axis about which the body is revolving be known in respect of the three principal axes supposed to be fixed in the system, together with the angular velocity of rotation; to determine the change of situation of the principal axes in respect of absolute space, in the element of time *dt*.

Fig. 14.



Imagine a sphere, whose radius = 1, to be described about O the centre of gravity of the body; let KTL (fig. 14) be a great circle, and in KTL assume a point T as that to which the position of the principal axes is to be referred. At the end of the time *t*, let X, Y, Z be the points in which the three principal axes passing through O meet the surface of the sphere; then, on joining these points by arcs of great circles, the three arcs XY, YZ, ZX will be quadrantal arcs, since the principal axes are at right angles to each other. Join also X, Y, Z with T by arcs of great circles, and assume

$$\text{TX} = l,\ \text{TY} = m,\ \text{TZ} = n,$$
$$\text{KTX} = \lambda,\ \text{KTY} = \mu,\ \text{KTZ} = \nu.$$

Let U be the point in which the axis about which the body is revolving at the end of the time *t* meets the surface of the sphere, and let U be joined by arcs of great circles with X, Y, Z. Put W = angular velocity of rotation about OU (which we suppose to be in the direction XYZ), and let α, β, γ be the angles which OU makes with the principal axes, namely, α = UX, β = UY, γ = UZ.

To investigate the motion of the point X, let X*e* be the small arc described by X in the instant *dt*; then this arc being perpendicular to UX, we have the angle YX*e* = UXZ, and sin. YX*e* = cos. YXU; also, since YXZ is a right angle, sin. TXY = cos. TXZ. Hence the formulæ of spherical trigonometry give the following equations,

$$\text{sin. YX}e = \frac{\text{cos.}\,\beta}{\text{sin.}\,\alpha}, \text{cos. YX}e = \frac{\text{cos.}\,\gamma}{\text{sin.}\,\alpha},$$

$$\text{cos. TXY} = \frac{\text{cos.}\,m}{\text{sin.}\,l}, \text{sin. TXY} = \frac{-\text{cos.}\,n}{\text{sin.}\,l};$$

from which, since TX*e* = YX*e* — TXY, we deduce

$$\text{sin. TX}e = \frac{\text{cos.}\,\beta\,\text{cos.}\,m + \text{cos.}\,\gamma\,\text{cos.}\,n}{\text{sin.}\,\alpha\,\text{sin.}\,l},$$

$$\text{cos. TX}e = \frac{\text{cos.}\,\gamma\,\text{cos.}\,m - \text{cos.}\,\beta\,\text{cos.}\,n}{\text{sin.}\,\alpha\,\text{sin.}\,l}.$$

Draw *ef* perpendicular to TX; then, because X*e* = W*dt* sin. α, we have X*f* = W*dt* sin. α cos. TX*e*, *ef* = W*dt* sin. α sin. TX*e*. But X*f* = — *dl*, *ef* = — sin. *ld* λ; therefore, by reason of the above values of sin. TX*e* and cos. TX*e*, and because W cos. $\beta = w'$, W cos. $\gamma = w''$, we have

$$\text{sin.}\,l\,dl = dt\,(w'\,\text{cos.}\,n - w''\,\text{cos.}\,m),$$
$$\text{sin.}^2\,l\,d\lambda = -\,dt\,(w'\,\text{cos.}\,m + w''\,\text{cos.}\,n).$$

It is evident that the consideration of the motion of each of the other two points Y and Z will lead to expressions entirely similar, and which may be concluded from analogy: we have therefore the following six equations to determine l, m, n, λ, μ, ν, namely,

$$\text{sin.}\,l\,dl = dt\,(w'\,\text{cos.}\,n - w''\,\text{cos.}\,m),$$
$$\text{sin.}\,m\,dm = dt\,(w''\,\text{cos.}\,l - w\,\text{cos.}\,n),$$
$$\text{sin.}\,n\,dn = dt\,(w\,\text{cos.}\,m - w'\,\text{cos.}\,l),$$
$$\text{sin.}^2\,l\,d\lambda = -\,dt\,(w'\,\text{cos.}\,m + w''\,\text{cos.}\,n),$$
$$\text{sin.}^2\,m\,d\mu = -\,dt\,(w''\,\text{cos.}\,n + w\,\text{cos.}\,l),$$
$$\text{sin.}^2\,n\,d\nu = -\,dt\,(w\,\text{cos.}\,l + w'\,\text{cos.}\,m).$$

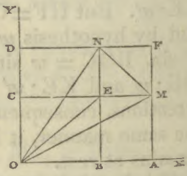
Because $\text{cos.}^2\,l + \text{cos.}^2\,m + \text{cos.}^2\,n = 1$, it is only necessary to solve two of the first three equations, in order to find the arcs l, m, n; and when the values of l, m, n have been obtained, it is only necessary to compute one of the three angles λ, μ, ν, in order to have the other two; for when one is known, the others are obtained from the equations cos. $(\mu - \lambda)$ = — cot. l cot. m, cos. $(\nu - \mu)$ = — cot. m cot. n, given by the triangles TYX and TYZ, of which the sides XY and YZ are arcs of 90°.

Rotation about a fixed point.

69. By means of the preceding propositions, we are enabled to determine the motion of a body which is at liberty only to turn about a fixed point. The statical principle on which the determination must be made is, that a body so circumstanced will be in a state of equilibrium, when the sums of the moments of the forces with reference to three rectangular axes drawn through the fixed point are nothing relatively to each of the three axes. It is therefore necessary in the first place to find expressions for these moments.

70. Suppose a material point whose co-ordinates are x and y to be urged by two forces, namely, a force = X, in the direction OX (fig. 15), and another force = Y in the direction OY, perpendicular to OX; then the efficacy of the two forces to turn the particle about the axis OZ perpendicular to the plane XOY, in the direction from X towards Y, is equal to Yx—Xy. For let M be the situation of the particle, and take MN to represent the intensity and direction of the single force into which X and Y may be compounded; through M and N draw MA, NB perpendicular to OX and MC, ND perpendicular to OY; let E be the point in which MC and NB intersect; join OM, ON, OE, and complete the parallelogram OF. Now the force represented by MN is compounded of the two forces represented by ME and EN; we have therefore, by construction,

Fig. 15.



$$\text{ME} = -\text{X} = \text{force in direction} - \text{OX},$$
$$\text{EN} = +\text{Y} = \text{force in direction OY}.$$

But the moment of the force MN in respect of the axis OZ is equal to MN multiplied into the line drawn from O perpendicular to MN, that is, equal to twice the triangle OMN, or to twice the sum of the triangles MOE, EON, MEN, or to the parallelograms MB, NC, EF, or to MB and CF. Now $\text{MB} = \text{AM} \cdot \text{ME} = -\text{X}y$, and $\text{CF} = \text{CD} \cdot \text{CM} = \text{Y}x$; therefore, the moment of the force MN, or of the two forces X and Y, is expressed by $\text{Y}x - \text{X}y$.

71. If we put Z = a force acting in the direction OZ perpendicular to the plane XOY, we shall evidently obtain similar expressions for the moments in respect of the other axes OX and OY; so that if we suppose the motion about OX to be in the direction from Z towards Y, and that about OY to be from X towards Z, and that about OZ to be from Y towards X, we shall have the three expressions,

$$\text{moment about OX} = \text{Y}z - \text{Z}y,$$
$$\text{about OY} = \text{Z}x - \text{X}z,$$
$$\text{about OZ} = \text{X}y - \text{Y}x.$$

72. If we now suppose P, Q, R to be the accelerating forces acting on a particle dm, in the directions of the three axes respectively, then (61) the quantities of motion lost by the particle at each instant, in consequence of the connexion of the parts of the system, or the differences between the impressed and effective forces, are

$$dm\left(\text{P}dt - \frac{ddx}{dt}\right),\ dm\left(\text{Q}dt - \frac{ddy}{dt}\right),\ dm\left(\text{R}dt - \frac{ddz}{dt}\right).$$

Substituting these differences for X, Y, Z respectively in the above expressions (71) for the moments of rotation, and forming the integrals in respect of dm, we shall get the sums of the moments in respect of all the particles about each of the three axes. But by the principle of D'Alembert (61), these sums must be severally = 0; therefore, if for brevity we put

$$\text{F} = \int(\text{Q}z - \text{R}y)\,dm,\ \text{G} = \int(\text{R}x - \text{P}z)\,dm,$$
$$\text{H} = \int(\text{P}y - \text{Q}x)\,dm,$$

there will result the three equations

$$\text{F}dt = \int ydm\,\frac{ddz}{dt} - \int zdm\,\frac{ddy}{dt}$$
$$\text{G}dt = \int zdm\,\frac{ddx}{dt} - \int xdm\,\frac{ddz}{dt},$$
$$\text{H}dt = \int xdm\,\frac{ddy}{dt} - \int ydm\,\frac{ddx}{dt}.$$

73. We have now to express these formulæ in terms of the angular velocities about the axes. Referring to fig. 14, let $x = \cos. l$, $y = \cos. m$, $z = \cos. n$, then x, y, z will be the co-ordinates of the point T referred to the rectangular axes OX, OY, OZ; and we shall have $dx = -\sin. ldl$, $dy = -\sin. mdm$, $dz = -\sin. ndn$. Substituting these values of x, y, z, and their differentials, in the three first of the system of equations in (68), and supposing the direction of the motion to be changed (namely, the rotation about OX to be in the direction from Z towards Y, and so with the other as in (71)), those three equations will become

$$dx = dt\,(w'z - w''y),$$
$$dy = dt\,(w''x - wz), \qquad \text{(A)}$$
$$dz = dt\,(wy - w'x).$$

If we now observe that OX, OY, OZ are principal axes, and consequently that $\int xydm = 0$, $\int xzdm = 0$, $\int yzdm = 0$, we shall find, on forming the expressions for ddz, ddy, and substituting always for dx, dy, dz their values as given by these equations,

$$\int ydm\,\frac{ddz}{dt} = \int y^2dm \cdot dw + w'w''\int y^2dm \cdot dt,$$
$$\int zdm\,\frac{ddy}{dt} = -\int z^2dm \cdot dw + w'w''\int z^2dm \cdot dt,$$

and consequently

$$\text{F}dt = \int(y^2 + z^2)\,dm \cdot dw + w'w''\int(y^2 - z^2)\,dm \cdot dt.$$

Similar expressions are obtained in the same manner for Gdt and Hdt. Now it is to be observed that $\int(y^2+z^2)\,dm$ is the moment of inertia with respect to the axis OX; if therefore we assume A, B, C to denote the moments of inertia in respect of the three axes respectively, that is, if we put

$$\text{A} = \int(y^2+z^2)\,dm,\ \text{B} = \int(x^2+z^2)\,dm,\ \text{C} = \int(x^2+y^2)\,dm,$$

the three equations of the last number will be transformed into the following:

$$\text{F}dt = \text{A}dw + (\text{C} - \text{B})\,w'w''dt,$$
$$\text{G}dt = \text{B}dw' + (\text{A} - \text{C})\,ww''dt, \qquad \text{(B)}$$
$$\text{H}dt = \text{C}dw'' + (\text{B} - \text{A})\,ww'dt.$$

74. These three equations enable us to determine the angular velocities of rotation about each of the principal axes when the forces F, G, H are known, and consequently suffice, when joined to the equations of (68) and the equations (A), for the determination of any point of the revolving body at any given instant of time reckoned from the commencement of the motion; for the values of w, w', w'' being supposed to be found in terms of t, and substituted in the two sets of equations of (68), the integrals of these equations will give the situation of the three principal axes at that instant, and the situation of the instantaneous axis of rotation, in respect of the principal axes, will be found by integrating the equations (A) after substituting in them the same values of w, w', w''.

75. When the body is subject to no accelerating forces, or the origin of the co-ordinates is placed at the centre of gravity, the integrations indicated in the last paragraph are obtained without difficulty; for in this case the quantities denoted by F, G, H, respectively vanish, and the equations (B) become

$$0 = \text{A}dw + (\text{C} - \text{B})\,w'w''dt,$$
$$0 = \text{B}dw' + (\text{A} - \text{C})\,ww''dt, \qquad (a)$$
$$0 = \text{C}dw'' + (\text{B} - \text{A})\,ww'dt.$$

Now if we multiply the first of these by w, the second by w', and the third by w'', and add the products, we shall have

$$0 = \text{A}wdw + \text{B}w'dw' + \text{C}w''dw'',$$

the integral of which is

$$\text{K} = \text{A}w^2 + \text{B}w'^2 + \text{C}w''^2, \qquad (b)$$

K being an arbitrary constant, and always positive. Again, let the same equations (a) be multiplied respectively by Aw, Bw', Cw'', and the products added and integrated; we shall then have, in like manner,

$$\text{L}^2 = \text{A}^2w^2 + \text{B}^2w'^2 + \text{C}^2w''^2, \qquad (c)$$

L² being another arbitrary constant, and always positive. From these two last equations we deduce

$$w'^2 = \frac{\text{CK} - \text{L}^2 + \text{A}\,(\text{A} - \text{C})\,w^2}{\text{B}\,(\text{C} - \text{B})},$$
$$w''^2 = \frac{\text{L}^2 - \text{BK} - \text{A}\,(\text{A} - \text{B})\,w^2}{\text{C}\,(\text{C} - \text{B})};$$

and on substituting the values of w' and w'' thus found in the first of the equations (a), and resolving the equations in respect of dt, we get

$$dt = \frac{\pm\sqrt{(\text{BC})}\cdot\text{A}dw}{\sqrt{\{\text{CK} - \text{L}^2 + \text{A}(\text{A} - \text{C})w^2\}\cdot\{\text{L}^2 - \text{BK} - \text{A}(\text{A} - \text{B})w^2\}}},$$

an equation of which the integral will be obtained in a finite form when any two of the three quantities A, B, C are equal (as in the case of a solid of revolution), or when L² is equal to any one of the three quantities AK, BK, CK. In any case, the relation between t and w is expressed by a single differential equation of the first order, the integral of which gives the value of w in terms of t, whence the values of w' and w'' are also given by the preceding formulæ.

Mechanical properties of the principal axes of rotation.

76. From the two equations (b) and (c) of last paragraph, a conclusion is deduced of considerable interest in the physical theory of the universe respecting the *stability* of the rotation about the axes of greatest and least

moment. Let the first of those equations be multiplied by C, and subtracted from the second; we shall have, on making $L^2 - CK = D$,

$$D = A(A - C)w^2 + B(B - C)w'^2.$$

Now, if we suppose the axis of instantaneous rotation to be situated at the commencement of the motion, very near the axis OZ, the angular velocity about which $= w''$, then the angle γ which it makes with that axis being very small, and since (66) $\sin.\gamma = \frac{\sqrt{(w^2 + w'^2)}}{\sqrt{(w^2 + w'^2 + w''^2)}}$, it follows that the angular velocities w and w' will be very small in comparison of w'', and consequently D must be a very small quantity. Now D is constant; and therefore if the two differences $A - C$ and $B - C$ have the same sign, which will be the case when the value of B is intermediate between A and C, the two velocities w and w' must always be very small; and hence (64) the instantaneous axis will never deviate much from OZ when this is the axis of greatest or of least moment. But if $A - C$ and $B - C$ have opposite signs, as will be the case when the value of C lies between the values of A and B, then D may be a very small quantity, and the equation still be satisfied, although the values of w and w' be large; and hence, although the axis of instantaneous rotation may have been very near the axis C at the commencement of the motion, it may deviate to any extent from that axis during the motion. Hence we infer that the rotation about the axes, both of greatest and least moment, is permanent, but that the rotation about the intermediate axis is not permanent.

77. The same conclusions may also be obtained by the direct integration of the equations (a) of (75), if we neglect, as insensible, the squares and products of the small velocities w and w'. Restricting the calculus to this approximation, the third equation (a) becomes $dw'' = 0$, whence $w'' = k$, k being an assured arbitrary constant. Substituting this value of w'' in the first two equations (a) we get

$$\left.\begin{aligned} 0 &= A\,dw + (C - B)\,kw'dt, \\ 0 &= B\,dw' + (A - C)\,kw\,dt. \end{aligned}\right\} \quad (d)$$

In order to integrate these, assume

$$w = \beta \sin.(qt + i),\ w' = \gamma \cos.(qt + i), \qquad (e)$$

the quantities β, γ, q, i being indeterminate constants. We have then

$$dw = q\beta \cos.(qt + i),\ dw' = -q\gamma \sin.(qt + i).$$

On substituting these values of w, w', dw, dw', and rejecting the common factors, the equations (d) become

$$0 = Aq\beta - (B - C)k\gamma,$$
$$0 = Bq\gamma - (A - C)k\beta,$$

from which we deduce $q = k\sqrt{(A - C)(B - C)} \div \sqrt{AB}$; and also, on assuming another indeterminate constant α, $\beta = \alpha\sqrt{B(B - C)}$, $\gamma = \alpha\sqrt{A(A - C)}$. Put $\lambda = \sqrt{(A - C)(B - C)} \div \sqrt{AB}$, then $q = \lambda k$; and the substitution of these values of q, β, γ in the equations (e) gives

$$w = \alpha\sqrt{B(B - C)} \sin.(\lambda kt + i),$$
$$w' = \alpha\sqrt{A(A - C)} \cos.(\lambda kt + i),$$

which are the complete integrals of the equations (d).

If in these expressions the quantity denoted by λ is real, which will be the case when C is the least or the greatest of the three moments, the values of w and w' must always continue small, because they are proportional to the sines and cosines of a real angle; but if C be intermediate between A and B, the λ will be an impossible quantity, and the sine and cosine of the arc $\lambda kt + i$ will be changed into exponentials which increase continually with the time t, whence the velocities w and w' will also increase indefinitely; and consequently, by Frisi's theorem, the deviation of the instantaneous axis of rotation from the original axis will increase indefinitely.

If we suppose that at the commencement of the motion the axis of instantaneous rotation coincided accurately with the principal axis OZ, we should have $w = 0$, $w' = 0$, when $t = 0$; and as in this case we have also $\alpha = 0$, w and w' will always be zero, or the body will continue for ever to revolve uniformly about OZ. We have therefore, from what precedes, these mechanical properties relative to the rotation of solid bodies: 1. If a body begins to revolve about any one of the three principal axes, and is affected by no external force, it will continue always to revolve about that axis; 2. If it begins to revolve about an axis which is very near the axis of the greatest or least moment, then, although the motion is disturbed a little by the action of an extraneous force, the instantaneous axis of rotation will continue very near the original axis; 3. If the rotation commences about the axis of the mean moment of inertia, then, if the smallest disturbance takes place, the effect will increase indefinitely with the time, and the poles of rotation will entirely change their position on the surface of the body. These properties establish an essential difference between the three principal axes.

Conclusion.

78. Our limits will not permit us to enter further into the discussion of this subject, nor is it within the scope of the present article to apply the formulæ to the rotation of the planets, an example of which application has already been given in the article Precession of the Equinoxes. It has now been shown that every circumstance relative to the motion of a solid body, acted upon by any number of forces, is expressed by means of two systems of equations (each containing three differential equations of the first order), the first system (62) defining the motion in space of the centre of gravity, and the second (73) the rotation about that centre. At the commencement of the motion these two systems are independent of each other; but it is important to remark, that this independence does not necessarily continue during the motion. If we suppose the moving forces to act upon different points of the body, and to be functions of the co-ordinates of those points, that is, to vary with their distance from the origin, then the coordinates enter at the same time into both systems of equations, which therefore cannot be integrated separately, the two motions affecting each other. The integrals can then only be obtained by approximation. There are, however, two important cases in which the two motions continue to be permanently independent of each other. The first is that of a projectile which, during its motion, is acted upon by no other force than gravity; for in this case the equations (62) will be those of an isolated material point, and the weight of the body, acting as a single force applied to the centre of gravity, will have no influence on the rotation, which will be the same as if the centre of gravity were fixed. The second is the case of a sphere, either homogeneous or composed of concentric strata of different densities, the density of each stratum being constant; for in this case the resultant of all the attractive forces, as was shown by Newton, passes through the centre of gravity, which will therefore move as an isolated point, and the motion of rotation will be the same as if the centre of gravity were fixed.

The theory of the rotation of solid bodies forming an important branch of mechanics, is treated more or less in every systematic work on that science. As the more important works in which it is especially considered, we may refer the reader to Euler's *Theoria Motus Corporum Solidorum*, 1765; D'Alembert, *Opuscula*, tom. v. and vii.; Vince *On the Principles of Progressive and Rotatory Motion*, Phil. Trans. 1780; Frisii *Opera*, tom. ii. 1783; Atwood's *Treatise on the Rectilinear Motion and Rotation of Bodies*, 1784; Landen's *Mathematical Memoirs*, vol. ii. 1789; Laplace, *Mécanique Céleste*, tom. i.; Lagrange, *Mécanique Analytique*; Poisson, *Traité de Mécanique*; Venturoli's *Mechanics*, translated by Cresswell; &c. (s.)

ROTHBURY, a small market-town in the county of Northumberland, pleasantly situated on the northern side of the river Coquet, over which there is a handsome stone bridge. The town consists of three wide and airy streets; and as the situation, from being screened by lofty hills from the north and east winds, is favourable to invalids, and the Coquet is well adapted for trout-fishing, many persons resort thither during the summer months, for health and amusement. The rectory is one of the richest livings in the county. The church is an ancient structure. The population in 1831 amounted to 1014.

ROTHENBURG, a city of the kingdom of Bavaria, and the capital of the bailiwick of the same name, in the circle of the Rezat. It is situated on the river Tauber, and is surrounded by ancient walls and thirty-three towers. It is built in the antique German style, comprehends a fine council-house, with eight churches, and contains 1160 houses, with 6400 inhabitants. Its chief trade is in the productions of its vicinity. Long. 11. 43. E. Lat. 49. 30. N.

Rothenburg, a city of the kingdom of Wirtemburg, in the circle of the Black Forest, and the capital of a bailiwick of its own name. It is situated on the river Neckar, which divides it into two parts, of which that on the left bank was formerly a distinct city called Ehingen. It is the seat of the Catholic hierarchy of the whole kingdom, with six churches of that sect, and contains 620 houses, with 5450 inhabitants. It has some trade in paper, leather, and breweries.

ROTHENFELS, a town of the kingdom of Bavaria, in the circle of the Lower Maine, and in a patrimonial bailiwick of the mediatized prince Lowenstein. It extends over eighty-four square miles, inhabited by 8500 persons. The town is situated on the river Maine, and contains 240 houses, with 1520 inhabitants, who are chiefly occupied in the cultivation of vines, and in making wine.

ROTHERHAM, a market-town of the west riding of the county of York, in the wapentake of Stratforth and Tickhill, 158 miles from London, and six from Sheffield. It is situated at the conflux of the rivers Rother and Don, which are navigable to Hull. There is a good market, which is held on Thursday. It is a considerable place for iron manufactures of the heavier kind. The population of the town amounted in 1801 to 3070, in 1811 to 2950, in 1821 to 3548, and in 1831 to 4083; but the parish contains eight other townships or hamlets, and the whole inhabitants amounted in 1831 to 10,417.

ROTHSAY, a town in the island and county of Bute, in Scotland. See Bute.

ROTHWELL, or sometimes called Rowell, a town of the county of Northampton, in the hundred of the same name, seventy-nine miles from London. It has lost its market. The population amounted in 1801 to 1409, in 1811 to 1451, in 1821 to 1742, and in 1831 to 1875.

ROTONDO, or Rotundo, in *Architecture*, an appellation given to any building that is round both within and without, whether it be a church, a saloon, or the like. The most celebrated rotundo of the ancients is the Pantheon at Rome.

ROTTERDAM, a city of the kingdom of Holland, and the capital of the circle of its own name. It is situated on the right bank of the river Maese, which here receives the waters of the river Rotte. It is a well-built city, in an antique style, with abundance of fine and large houses, many of them five or six stories in height. The Boomjee, a row of houses facing the river, with a broad quay between, planted with trees, is perhaps one of the finest promenades in Europe. The city is intersected with canals, and by means of them the goods from ships are brought to the warehouses of the merchants, which are at the backs of their houses; and by the same means the productions intended for exportation are brought to the several places of deposit. The markets also are supplied from the country by means of these canals; and on the market-days, instead of the roads being filled with carts and waggons, the canals are crowded with country barges. These barges are drawn more by men than horses, and indeed horses are rarely seen in the streets. Many of the public buildings are of a magnificent appearance. Amongst these, that of the defunct East India Company, now added to the customhouse, may be viewed with admiration. The house of the assembly of the ancient states of Zealand was built at an early period of the establishment of the independence of the United States. It is spacious, being in the most sumptuous style of the architecture of that age; and when Bonaparte assumed the sovereignty of the country, it was decorated and furnished for his residence at the expense of the city. The ancient stadthouse has been appropriated to other than its original purpose; and a new modern building has been erected, whose portico, although massive, is elegant, as far as regards the pillars that support it. The ecclesiastical buildings belonging to the Calvinists are the most ancient and the largest, particularly the church of St Lawrence. It has an organ, lately erected, of the greatest power of any in existence, and said to contain eight hundred pipes more than the celebrated organ of Harlem. The Lutheran church is a large and fine building. There are three churches where the service is in English; one for the Episcopalian, one for the Kirk of Scotland, and one for Independents, in the latter of which the celebrated Hugh Peters once officiated.

The trade of Rotterdam is very extensive. That to the West Indies has declined of late years, but that to the East Indies, chiefly to Batavia, has been recently very beneficial; and its commerce for the last fifteen years has increased more rapidly than that of any town in the kingdom. The fishery is an extensive source of employment and wealth. The trade with the Baltic employs much shipping, and affords moderate-priced corn for the distillers of gin. The business of ship-building employs many persons, both in the government arsenal and in the private docks; and the vessels now built are admirably constructed and equipped. The supply of colonial produce to the interior of Germany by the Rhine is very beneficial. The population of the city amounted in 1832 to 72,294. Long. 4. 29. 14. E. Lat. 51. 55. 9. N.

ROTTINGDEAN, a village of the county of Sussex, in the hundred of Youngsmere, and rape of Lewes, fifty-six miles from London, and four from Brighton. It is situated on the sea-shore, between two cliffs, and is much resorted to in the summer season by bathing visitors who wish for retirement. The population amounted in 1801 to 543, in 1811 to 559, in 1821 to 772, and in 1831 to 880.

ROUBAIX, a large market-town of France, in the department of the North, and the arrondissement of Lisle. It is a place of extensive manufactories, formerly of woollens, but of late years almost exclusively of cottons. There are several mills for spinning; and a great quantity of quiltings, dimities, nankeens, and other cotton articles, are made, and of good quality. The town, in 1836, contained 18,187 inhabitants.

ROUEN, an arrondissement of the department of the Lower Seine, in France. It extends over 456 square miles, and comprehends fifteen cantons, divided into 155 communes, which, in 1836, contained 238,805 inhabitants. The capital is the city of the same name, situated in a valley on the banks of the Seine, over which there is a bridge of boats leading to the suburb St Sever. The river Robec passes through a part of the city, and falls into the Seine, and in its progress gives power to several mills and other machinery. It is not a well-built town, having many large but antique houses, and others of wood, with narrow and crooked streets. It is the see of an archbishop, whose cathedral, as well as the church of St Ouen, are noble specimens of Gothic architecture. There is an academy of arts and sciences, with a library of seventy thousand volumes, and institutions for various branches of education. It is the chief seat of the cotton manufacture, and hence has vastly increased since the peace in population and in wealth. There are many other goods made here, such as various kinds of thin stuffs, and other woollens, linen of all qualities, combs, vitriol, aquafortis, tin wares, and porcelain, besides refined sugar. The neighbourhood is celebrated for its apples and pears. It contains above 11,500 houses, and in 1836 the inhabitants amounted to 92,083. Long. 1. 0. 39. E. Lat. 49. 26. 27. N.

ROUNDA, a town of Hindustan, in the Mahratta territories, and the province of Kandeish. It is situated on the east side of the Ghirah river, forty-six miles south-west from Burhampoor. Long. 75. 47. E. Lat. 20. 54. N.

ROUNDELAY, or Rondo, a sort of ancient poem, deriving its name, according to Ménage, from its form, and because it still turns back again to the first verse, and thus goes round. The common roundelay consists of thirteen verses, eight of which are in one rhyme and five in another. It is divided into couplets, at the end of the second and third of which the beginning of the roundelay is repeated, and that, if possible, in an equivocal or a punning sense. The roundelay is a popular poem in France, but is little known amongst us. Marrot and Voiture have succeeded the best in it. Rapin remarks, that if the roundelay be not very exquisite, it is intolerably bad. In all the ancient ones, observes Ménage, the verse preceding has a less complete sense, and yet joins agreeably with that of the close, without depending necessarily thereon. This rule, well observed, makes the roundelay more ingenious, and is one of the artifices of the poem. Some of the ancient writers speak of the roundelay or roundel as a kind of air appropriated to dancing; and in this sense the term seems to indicate little more than dancing in a circle with the hands joined.

ROUND-HOUSE, a kind of prison for the nightly watch in London, to secure disorderly persons till they can be carried before a magistrate.

ROUNDS, in military matters, a detachment from the main-guard, of an officer or a non-commissioned officer and six men, who go round the rampart of a garrison, to listen if any thing be stirring without the place, and to see that the sentinels be diligent upon their duty, and all in order. In strict garrisons the rounds go every half-hour. The sentinels have orders to challenge at a distance, and to rest their arms as the round passes. All guards turn out, challenge, exchange the parole, and rest their arms.

ROUSSEAU, James, an eminent French painter, was born at Paris in the year 1630. He studied first under Swanevelt, who had married one of his relations; after which he improved himself by travelling into Italy, practising solely perspective, architecture, and landscape. On his return home, he was employed at Marly. He distinguished himself very much in painting buildings, and by his knowledge of, and his attention to, the principles of perspective. Louis XIV. employed him to decorate his hall of devices at St Germaine-en-Laie, where he represented the operas of Lulli; but being a Protestant, he quitted France on the persecution of his brethren, and retired to Switzerland. Louis invited him back. He refused, but sent his designs, and recommended a proper person to execute them. After a short stay in Switzerland, he went to Holland, whence he was invited to England by Ralph duke of Montague, to adorn his new house in Bloomsbury. Here he painted a great deal. Some of his pictures, both in landscape and architecture, are over doors at Hampton Court; and he etched several of his own designs. His perspectives, having been most commonly applied to decorate courts or gardens, have suffered much from the weather. Such of them as remain are monuments of an excellent genius. The colours are bright and durable, and the choice of them most judicious. He died in Soho Square about the year 1694, at the age of sixty-four.

Rousseau, *John Baptist*, a celebrated French poet, was born at Paris in April 1669. His father, who was a shoemaker in good circumstances, made him study in the best colleges of Paris, where he distinguished himself by his abilities. He at length applied entirely to poetry, and soon made himself known by several short pieces, that were filled with lively and agreeable images, which made him sought for by persons of the first rank, and men of the brightest genius. He was admitted, in quality of pupil, into the Academy of Inscriptions and Belles Lettres in 1701, and almost all the rest of his life he attached himself to some great men. He attended Marshal Tallard into England in quality of secretary, and there contracted a friendship with St Evremond. At his return to Paris, he was admitted into the politest company, lived amongst the courtiers, and seemed perfectly satisfied with his situation; when, in 1708, he was prosecuted for being the author of some couplets, in which the characters of several persons of wit and merit were blackened by the most atrocious calumnies. This prosecution made much noise; and Rousseau was in 1712, by a decree of the parliament of Paris, banished out of the kingdom, to which he was never more to return. However, he always steadily denied, even on his death-bed, his being the author of these couplets. From the date of this sentence he lived in foreign countries, where he found illustrious protectors. The Count de Luc, ambassador of France, in Switzerland, took him into his family, and studied to render his life agreeable. He carried him to the treaty of Baden in 1714, where he was one of the plenipotentiaries, and presented him to Prince Eugene, who, entertaining a particular esteem for him, took him to Vienna, and introduced him to the emperor's court. Rousseau lived about three years with Prince Eugene; but having lost his favour by satirizing one of his mistresses, he retired to Brussels, where he afterwards usually resided. It was there that he commenced his disputes with Voltaire, with whom he had become acquainted at the college of Louis the Great, and who then much admired his turn for poetry. Rousseau, from the period of their dispute, always represented Voltaire as a buffoon, and as a writer possessing neither taste nor judgment, who owed all his success to a particular mode which he pursued. As a poet he considered him as inferior to Lucan, and little superior to Pradon. Voltaire treated him still worse. Rousseau, according to him, was nothing better than a plagiarist, who had nothing but the talent of arranging words. He came over, in 1721, to London, where he printed a Collection of his Works, in two volumes 12mo. This edition, published in 1723, brought him near ten thousand crowns, the whole of which he placed in the hands of the Ostend Company. The affairs of this company, however, soon getting into confusion, those who had any money in their hands lost the whole of it; by which unfortunate event Rousseau, when arrived at that age when he stood most in need of the comforts of fortune, had nothing to depend upon but the generosity of some friends. He died at Brussels in February 1740. A very beautiful edition of his works was published in 1743, at Paris, in three volumes 4to, and in four volumes 12mo, containing nothing but what was acknowledged by the author as his own. It contains, 1. Four Books of Odes, of which the first are sacred odes, taken from the Psalms; 2. Two Books of Epistles, in verse; 3. Cantatas, in which species of poetry he stands unrivalled; 4. Allegorics, the most of which are happy, but some of them appear forced; 5. Epigrams, after the manner of Martial and Marot; 6. A book of Poems on Various Subjects; 7. Four Comedies, in verse; 8. Three Comedies, in prose; and, 9. A Collection of Letters, in prose. A good edition of his Select Pieces appeared at Paris in 1741, in a small 12mo volume.

ROUSSEAU, *John-James*, one of the most renowned writers of modern times, was born at Geneva on the 28th of June 1712. His father was by profession a clock and watch maker. At his birth, which, he says, was the first of his misfortunes, he endangered the life of his mother; and he himself was for a long time afterwards in a very weak and languishing state of health. But as his bodily strength increased, his mental powers gradually opened, and afforded the happiest presages of future greatness. His father, a citizen of Geneva, was a well-informed tradesman; and in the place where he wrought he kept a Plutarch and a Tacitus, authors which of course soon became familiar to his son. A rash juvenile step, however, occasioned his leaving his father's house. "Finding himself a fugitive in a strange country, and without money or friends, he changed his religion, in order to procure a subsistence." Bornex, bishop of Anneci, from whom he sought an asylum, committed the care of his education to Madame de Warrens, a lady, who in 1726 had left part of her wealth, and the Protestant religion, in order to throw herself into the bosom of the Catholic church. This generous lady served in the triple capacity of a mother, a friend, and a lover, to the new proselyte, whom, in fact, she regarded as her son. The necessity of procuring for himself some settlement, however, or perhaps his unsettled disposition, obliged Rousseau often to take leave of this tender mother.

He possessed more than ordinary talents for music; and the Abbé Blanchard flattered his hopes of a place in the royal chapel, which he, however, failed in obtaining for him. He was therefore under the necessity of teaching music at Chamberi. He remained in this place till 1741, in which year he went to Paris, where he was long in very destitute circumstances. Writing to a friend in 1743, he thus expresses himself: "Every thing is dear here, especially bread." But he at length began to emerge from that obscurity in which he had hitherto been buried; and his friends placed him with M. de Montaigne, ambassador from France to Venice. According to his own confession, a proud misanthropy, and a peculiar contempt of the riches and pleasures of this world, constituted the chief traits in his character; and a misunderstanding soon took place between him and the ambassador. The place of depute, under M. Dupin, farmer-general, a man of considerable parts, gave him some temporary relief, and enabled him to be of some benefit to Madame de Warrens, his former benefactress. But the year 1750 proved the commencement of his literary career. The academy of Dijon had proposed the following question: "Whether the revival of the arts and sciences has contributed to the refinement of manners?" Rousseau at first inclined to support the affirmative. "Take the negative side of the question," said a philosopher, who was at that time his friend, "and I'll promise you the greatest success."

His discourse against the sciences having been found to be the best written, and replete with brilliant reasoning, was publicly crowned with the approbation of that learned body. Never was a paradox supported with greater eloquence. It was not however a new one; but he enriched it with all the advantages which either knowledge or genius could confer upon it. Immediately after its appearance, he met with several opponents of his tenets, which he defended; and, from one dispute to another, he found himself involved in a formidable train of correspondence, without having ever almost dreamed of such opposition. From that period he decreased in happiness as he increased in celebrity. His Discourse on the Causes of Inequality amongst Mankind, and on the Origin of Social Compacts, was written with a view to prove that mankind are equal; that they were born to live apart from each other; and that they have perverted the order of nature in forming societies. He bestows the highest praise on the State of Nature, and deprecates the idea of every social compact. By presenting this performance to the magistrates of Geneva, he was received again into his native country, and reinstated in all the privileges and rights of a citizen, after having with much difficulty prevailed on himself to abjure the Catholic religion. He soon returned to France, however, and lived for some time in Paris. He afterwards gave himself up to retirement, partly to escape the shafts of criticism, and partly to follow the regimen which the strangury, with which he was afflicted, necessarily required. This is an important epoch in the history of his life, as it was owing to this circumstance, perhaps, that we have the most elegant works that have proceeded from his pen. His Letter to M. d'Alembert on the design of erecting a theatre at Geneva, written in his retirement, and published in the year 1757, contains, along with some paradoxes, some very important and well-handled truths. This letter first drew down upon him the envy of Voltaire, and was the cause of those indignities with which that author never ceased to load him. Although so great an enemy to theatrical representations, he caused a comedy to be printed; and in 1752 he gave to the theatre a pastoral, called the Village Conjuror, of which he composed the poetry and the music, both of them abounding with sentiment and elegance, and full of innocent rural simplicity. His Dictionary of Music affords several excellent articles; some of them, however, are extremely inaccurate. "This work," says M. la Borde, in his Essay on Music, "has need to be written over again, to save much trouble to those who wish to study it, and prevent them from falling into errors, which it is difficult to avoid, from the engaging manner in which Rousseau drags along his readers." Soon after the rapid success of his Village Conjuror, he published a Letter on French Music, or rather against French Music, written with equal freedom and liveliness. The exasperated partisans of French comedy treated him with as much fury as if he had conspired against the state; and a crowd of enthusiasts spent their strength and outcries against him. He was insulted, menaced, and lampooned.

That interesting and tender style which is so conspicuous throughout the Village Conjuror, animates several letters in the *Nouvelle Heloise*, which was published in 1761 in 12mo. This epistolary romance, of which the plot is ill managed, and the arrangement bad, like most other works of genius, has its beauties as well as its faults. Some of the letters are indeed admirable, from the force and warmth of expression, from an effervescence of sentiment, and from the irregularity of ideas which always characterize a passion carried to its height. In the Heloise, Rousseau's unlucky talent of rendering every thing problematical appears very conspicuous. This is the case in his arguments in favour of and against duelling, which afford an apology for suicide, and a just condemnation of it; his facility in palliating the crime of adultery, and his strong reasons to make it abhorred; his declamations against social happiness, and transports in favour of humanity; his violent rhapsodies against philosophers, and his rage for adopting their opinions; the existence of God attacked by sophistry, and atheists confuted by the most irrefragable arguments; the Christian religion combated by the most specious objections, and celebrated by the most sublime eulogies.

His Emilius afterwards made more noise than the New Heloise. This moral romance, which was published in the year 1762, in four volumes 12mo, treats chiefly of education. Rousseau wished to follow nature in every thing; and though his system in several places differs from received ideas, it deserves in many respects to be put in practice, and with some necessary modifications it has been so. His precepts are expressed with the force and dignity of a mind full of the leading truths of morality. If he has not always been virtuous, nobody at least has felt it more, or made it appear to greater advantage. What is most to be lamented is, that in wishing to educate a young man as a Christian, he has filled a volume with objections against Christianity. It must be confessed that he has given a very sublime eulogium on the gospel, and an affecting portrait of its divine Author; but the miracles and the prophecies, which serve to establish his mission, he attacks without reserve. Admitting only natural religion, he weighs every thing in the balance of reason; and this reason being false, leads him into dilemmas which are very unfavourable to his own repose and happiness. The French parliament condemned this book in 1762, and entered into a criminal prosecution against the author, which forced him to make a precipitate retreat. He directed his steps towards his native country, but it shut its gates upon him. Proscribed in the place where he had first drawn breath, he sought an asylum in Switzerland, and found one in the principality of Neufchatel. But the protection of the king of Prussia, to whom the principality belonged, was not sufficient to rescue him from that obloquy which the minister of Moutiers-Travers, the village to which he had retired, had excited against him. He preached against Rousseau, and his sermons produced an uproar amongst the people. On the night between the 6th and the 7th of September 1765, some fanatics, inspired by wine and the declamations of their minister, threw stones at the windows of the Genevan philosopher, who, fearing new insults, in vain sought an asylum in the canton of Berne. As this canton was connected with the republic of Geneva, they did not think proper to allow him to remain in their city, who was proscribed by that republic. Neither his broken state of health, nor the approach of winter, could soften the hearts of these obdurate Switzers. To prevent them from the fear they had of the spreading of his opinions, he in vain beseeched them to shut him up in prison till the spring. But even this favour was denied him. Obliged to set out on a journey in the beginning of a most inclement season, he reached Strasbourg in a very destitute situation. He received from Marshal de Contades, who then commanded in that place, every accommodation which could be expected from generosity, humanity, and compassion. He waited there till the weather became milder, when he went to Paris, where Mr Hume then was. The English philosopher determined upon taking him with him to England. After having made some stay in Paris, Rousseau, in 1766, actually set out for London. Hume, much affected with his situation and his misfortunes, procured for him a very agreeable retreat in the country. The Genevan philosopher, however, did not long remain satisfied. He made less impression on the minds of the English than he had done on the French. His free disposition, and his obdurate melancholy temper, were deemed no singularity in England. He was there looked upon as an ordinary man, and the periodical prints were filled with satires against him. In particular, they published a forged letter from the king of Prussia, holding up to ridicule the principles and conduct of this new Diogenes. Rousseau, imagining there was a plot between Hume and some philosophers in France to destroy his glory and repose, sent a letter to him, filled with the most abusive expressions, and reproaching him for his conduct towards him. From this time he looked upon Hume as a wicked and perfidious person, who had brought him to England with no other view than to expose him to public ridicule; a foolish and chimerical idea, which was nourished by self-love and a restless disposition. He imagined that the English philosopher, amidst all his kindnesses, had something disagreeable in the manner of expressing them. The bad health of Rousseau, a strong and melancholy imagination, a too nice sensibility, a jealous disposition, joined with philosophical vanity, cherished by the false informations of his governess, who possessed an uncommon power over him; all these taken together might have tended to prepossess him with unfavourable sentiments of some innocent freedoms his benefactor might have taken with him, and might have rendered him ungrateful, which he thought himself incapable of becoming. Meanwhile these false conjectures and probabilities ought never to have had the weight with an honest mind to withdraw itself from its friend and benefactor. Proofs are always necessary in cases of this kind; and that which Rousseau had was by no means a certain demonstration. The Genevan philosopher, however, returned to France, spited with the world, and particularly offended with the English philosopher. On the 1st of July 1770, he appeared for the first time at the regency coffee-house, dressed in his ordinary clothing, having for some time previous to this worn an Armenian habit. He was loaded with praises by the surrounding multitude. "It is somewhat singular," says M. Sennebier, "to see a man so haughty as he returning to the very place from whence he had been banished so often. Nor is it one of the smallest inconsistencies of this extraordinary character, that he preferred a retreat in that place of which he had spoken so much ill." It is as singular that a person under sentence of imprisonment should wish to live in so public a manner in the very place where his sentence was in force against him. His friends, however, procured for him the liberty of staying, on condition that he should write neither on religion nor on politics; and he kept his word, for he wrote none at all. He was contented with living in a calm and philosophical manner, cultivating the society of a few tried friends, shunning the company of the great, appearing to give up all his whimsics, and affecting neither the character of a philosopher nor a wit. He died of an apoplexy, at Ermenonville, about ten leagues from Paris, on the 2d of July 1778, aged sixty-six years. Rousseau, during his stay in the environs of Lyons, married Mademoiselle le Vasseur, a woman who, without either beauty or talents, had gained over him a great ascendency, and waited on him both in health and in sickness. But, as if she had been jealous of possessing him alone, she drove from his mind, by the most perfidious insinuations, all those who came to entertain him; and when he did not dismiss them, she prevented their return by invariably refusing them admittance. By these means she the more easily led her husband into inconsistencies of conduct, which the originality of his character, as well as of his opinions, so much contributed to assist. He did not incline to associate with any person; and as this method of thinking and living was uncommon, it made him an object of curiosity, and procured him a name. Like Diogenes of old, he united simplicity of manners with pride of genius; and a very large stock of indolence, with an extreme sensibility, served to render his character still more uncommon. "An indolent mind," says he, "terrified at every application, a warm, bilious, and irritable temperament, sensible also in a high degree to every thing that can affect it, appear not possible to be united in the same person; and yet these two contrarieties compose the chief of mine. An active life has no charms for me. I would an hundred times rather consent to be idle than to do any thing against my will; and I have an hundred times thought that I would live not amiss in the Bastille, provided I had nothing to do but just continue there. In my younger days I made several attempts to get in there; but as they were only with the view of procuring a refuge and rest in my old age, and, like the exertions of an indolent person, only by fits and starts, they were never attended with the smallest success. When misfortunes came, they afforded me a pretext for giving myself up to my ruling passion."

His ideas about politics were almost as eccentric as his paradoxes about religion. Some reckon his Social Compact, which Voltaire calls the Unsocial Compact, the greatest effort of his genius; whilst others find it full of contradictions, errors, and cynical passages, obscure, ill arranged, and by no means worthy of his pen. There were found in his portfolio his Confessions, in twelve books; the first six of which were published. "His Confessions," says Sennebier, in his Literary History of Geneva, "appear to me to be a very dangerous book, and paint Rousseau in such colours as we would never have ventured to apply to him. The excellent analyses which we meet with of some sentiments, and the delicate anatomy which he makes of some actions, are not sufficient to counterbalance the detestable matter which is found in them, and the unceasing obloquies everywhere to be met with." Amongst his other posthumous pieces are the following. 1. The Reveries of a Solitary Wanderer, being a journal of the latter part of his life.[1] 2. Considerations upon the Government of Poland. 3. The Adventures of Lord Edward, a novel, being a kind of supplement to the new Heloisa. 4. Various Memoirs and Fugitive Pieces, with a great number of letters, containing some eloquent passages and deep thoughts. 5. Emilia and Sophia. 6. The Levite of Ephraim, a poem in prose, in four cantos, written in a style of ancient simplicity. 7. Letters to Sara. 8. An Opera and a Comedy. 9. Translations of the first book of Tacitus's History, of the Episode of Olinda and Sophronia, from Tasso, &c. Like all the other writings of Rousseau, we find in these posthumous pieces many admirable and some useful things; but they also abound with contradictions, paradoxes, and ideas very unfavourable to religion. In his letters, especially, we see a man chagrined at misfortunes which he never attributes to himself; suspicious of every body about him, calling and believing himself a lamb in the midst of wolves. Viewing him solely as a writer, his character is perhaps described with truth and accuracy in the following words of Mr Hume. "Though I see some tincture of extravagance in all his writings, I also think I see so much eloquence and force of imagination, such an energy of expression, and such a boldness of conception, as entitle him to a place amongst the first writers of his age." His works, in the best edition, published in 1788 and the following years, extend to thirty-seven volumes octavo.

ROUSSELAER, or Roulers, a city of Belgium, in the province of West Flanders, and the circle of Courtray. It is situated on the river Mandelbeke, and has a royal college, with eight professors. It contains 1100 houses, with 8840 inhabitants, who are occupied in making linen goods of various kinds, in refining salt, and in cultivating fine flax.

ROVEREDO, a city of the Austrian province of Tyrol, the capital of a circle of the same name, which extends over 748 square miles, and contains, in three cities and towns, and 355 villages, 95,600 inhabitants. It is an open place, situated on the river Etsch, is well built, and defended by a strong fortress, and contains more than 1000 houses, with about 12,000 inhabitants. It is a great place for the several branches of the silk trade, which affords occupation to two thirds of the population. The silk produced near it is very highly esteemed. Long. 10. 55. 5. E. Lat. 45. 55. 36. N.

ROVIGNO, a city of the Austrian government of Trieste, and the capital of a district of the same name, which extends over 399 square miles, and contains 26,900 inhabitants. It is situated on a promontory running into the sea, and is well built, containing ten churches, 1150 houses, and 10,650 inhabitants. It has two harbours, with good wharfs, several yards for ship-building, and extensive fisheries, especially for anchovies. Near to it the vine and the olive are extensively cultivated, and very productive. Long. 13. 43. 15. E. Lat. 45. 1. 30. N.

ROVIGO, a city of Austrian Italy, in the province of Milan, and the capital of the delegation of Polesina. It is situated on the river Adigetto, over which are four bridges, by which it is connected with its suburbs. It is fortified, and is the seat of the bishop of Adria, who has a palace and an ecclesiastical seminary, and twenty-six churches, under his care. It contains 1200 houses, with 6950 inhabitants, who are chiefly employed in making leather and in refining saltpetre. Long. 11. 42. 43. E. Lat. 45. 3. 57. N.

ROWE, Nicholas, was descended of an ancient family in Devonshire, and born in 1673. He acquired a complete taste for the classical authors under Dr Busby in Westminster school; but poetry was his early and darling study. His father, who was a lawyer, entered him a student in the Middle Temple, and he made remarkable advances in the study of the law; but the love of the belles lettres, and of poetry, stopped him in his career. His first tragedy, the Ambitious Stepmother, meeting with universal applause, he laid aside all thoughts of rising by the law, and afterwards composed several tragedies; but that which he valued himself most upon was his Tamerlane. The others were, the Fair Penitent, Ulysses, the Royal Convert, Jane Shore, and Lady Jane Grey. He also wrote a poem called the Biter, and several poems upon different subjects, which have been published under the title of Miscellaneous Works, in one volume, as his dramatic works have been in two. Rowe is chiefly to be considered in the light of a tragic writer and a translator. In his attempt at comedy, he failed so ignominiously that his Biter is not inserted in his works; and his occasional poems and short compositions are rarely worthy either of praise or censure, for they seem to be the casual sports of a mind seeking rather to amuse its leisure than to exercise its powers. In the construction of his dramas there is not much art; and he is not a nice observer of the unities. I know not, says Dr Johnson, that there can be found in his plays any deep search into nature, any accurate discrimination of kindred qualities, or nice display of passion in its progress. All is general and undefined. Nor does he much interest or affect the auditor, except in Jane Shore, who is always seen and heard with pity. Alicia is a character of empty noise, with no resemblance to real sorrow or to natural madness. Whence then has Rowe acquired his reputation? From the reasonableness and propriety of some of his scenes, from the elegance of his diction, and from the suavity of his verse. He seldom moves either pity or terror, but he often elevates the sentiment; he seldom pierces the breast, but he always delights the ear, and often improves the understanding. Being a great admirer of Shakspeare, he gave the public an edition of his plays, to which he prefixed an account of his life. But the most considerable of Mr Rowe's performances was a translation of Lucan's *Pharsalia*, which he just lived to finish, but not to publish; for it did not appear in print till 1728, ten years after his death.

In the meanwhile, the love of poetry and books did not make him unfit for business; for nobody applied closer to it when occasion required. The Duke of Queensberry, when secretary of state, made him secretary for public affairs. But after the duke's death, all avenues to his preferment were stopped; and during the remainder of Queen Anne's reign he passed his time with the Muses and his books. On the accession of George I., however, he was made poet-laureat, and one of the land-surveyors of the customs in the port of London. The Prince of Wales conferred on him the clerkship of his council; and the Lord Chancellor Parker made him his secretary for the presentations. But he did not enjoy these promotions long; for he died on the 6th of December 1718, being then in his forty-fifth year.

Mr Rowe, who was twice married, had a son by his first wife, and a daughter by his second. He was a very handsome man; and his mind was as amiable as his person. He lived beloved; and at his death he had the honour to be lamented by Pope, in an epitaph which is printed in Pope's works, although it was not affixed on Mr Rowe's monument in Westminster Abbey, where he was interred, in the poets' corner, opposite to Chaucer.

---

[1] In this he confesses that he liked better to send his children into hospitals destined for orphans, than to take upon himself the charge of their maintenance and education, and endeavours to palliate this offence, which nothing can exculpate.

Rowe, *Elizabeth*, an English lady, eminent for her writings both in prose and verse, was born at Ilchester, in Somersetshire, in 1674, being the daughter of worthy parents, Mr Walter Singer and Mrs Elizabeth Portnel. There being a great affinity between painting and poetry, this lady, who had a vein for the one, naturally had a taste for the other. She was also very fond of music, chiefly of the grave and solemn kind, as best suited the grandeur of her sentiments and the sublimity of her devotion. But poetry was her favourite employment, her distinguishing excellence; and so prevalent was her genius this way, that her prose is all poetical. In 1696, a collection of her poems was published at the desire of two friends. Her paraphrase on the thirty-eighth chapter of Job was written at the request of Bishop Ken. She had no other tutor for the French and Italian languages than Mr Thynne, who willingly took the trouble upon himself. Her shining merit, with the charms of her person and conversation, had procured her many admirers. Amongst others, it is said, the famous Mr Prior made his addresses to her; but Mr Thomas Rowe was destined to be the happy man. This gentleman was honourably descended; and his superior genius, and insatiable thirst after knowledge, were conspicuous in his earliest years. He had formed a design to compile the lives of all the illustrious persons in antiquity omitted by Plutarch; which, indeed, he partly executed, and eight lives were published after his decease. They were translated into French by the Abbé Bellenger in 1734. He spoke with ease and fluency, and had a frank and benevolent temper, an inexhaustible fund of wit, and a communicative disposition. Such was the man who, charmed with the person, character, and writings of our authoress, married her in 1710, and made it his study to repay the felicity with which she crowned his life. But too intense an application to study, beyond what the delicacy of his frame would bear, broke his health, and threw him into a consumption, which put a period to his life in May 1715, when he had but just passed the twenty-eighth year of his age. Mrs Rowe wrote a beautiful elegy on his death; and continued to the last moments of her life to express the highest veneration and affection for his memory. As soon after his decease as her affairs would permit, she indulged her inclination for solitude by retiring to Frome, in Somersetshire, in the neighbourhood of which place lay the greatest part of her estate. In this recess it was that she composed the most celebrated of her works, Friendship in Death, and the Letters Moral and Entertaining. In 1736, she published the History of Joseph, a poem which she had written in her younger years. But she did not long survive this publication; for she died of an apoplexy, as was supposed, on the 20th of February 1736-1737. In her cabinet were found letters to several of her friends, which she had ordered to be delivered immediately after her decease. Dr Isaac Watts, agreeably to her request, revised and published, in 1737, her devotions, under the title of Devout Exercises of the Heart in Meditation and Soliloquy, Praise and Prayer; and, in 1739, her Miscellaneous Works, in prose and verse, were published in two volumes 8vo, with an account of her life and writings prefixed.

ROWEL, amongst farriers, a kind of issue, answering to what in surgery is called a seton.

ROWLEY, a monk who is said to have flourished at Bristol in the fifteenth century. Of the poems attributed to him various opinions have been entertained, which we have noticed under the article on Chatterton.

Rowley, *William*, who stands in the third class of dramatic writers, lived in the reign of King Charles I. and received his education at the University of Cambridge; but whether he took any degree there, is not evident, there being but few particulars preserved in regard to him, except his close intimacy and connection with all the principal wits and poetical geniuses of that age, by whom he was well beloved, and with some of whom he joined in their writings. Wood styles him "the ornament, for wit and ingenuity, of Pembroke Hall in Cambridge." In a word, he was a very great benefactor to the English stage, having, exclusively of his aid lent to Middleton, Day, Heywood, Webster, and others, left us five plays of his own composition, and one in which even the immortal Shakspeare afforded him some assistance.

Rowley Regis, a town of the parish of Dudley, in Worcestershire, although within the hundred of Seisdon, in Staffordshire, and chiefly inhabited by nail-makers and other workers in iron. The population amounted in 1801 to 5027, in 1811 to 4974, in 1821 to 6062, and in 1831 to 7438.

ROWNING, John, an English mathematician and philosopher of considerable ingenuity, was fellow of Magdalen College, Cambridge, and afterwards rector of Anderby in Lincolnshire, in the gift of that society. He constantly attended the meetings of the Spalding Society, and was a man of an extraordinary philosophical habit of mind, whilst at the same time his dispositions were social and cheerful. His genius was peculiarly fitted for mechanical contrivances or inventions. He published a compendious system of Natural Philosophy at Cambridge, in the year 1738, in two volumes 8vo; a work of much ingenuity, which has gone through several editions. He likewise inserted two pieces in the Philosophical Transactions, namely, a description of a barometer, wherein the scale of variation may be increased at pleasure (vol. xxxviii. p. 39); and directions for making a machine for finding the roots of equations universally, together with the manner in which it should be used (vol. lx. p. 240). He died at his lodgings in Carey Street, near Lincoln's-Inn Fields, in the end of November 1771, in the seventy-second year of his age. Though a man both ingenious and pleasant, his external appearance was rather forbidding, being tall, and low in the shoulders, with his countenance down-looking and sallow.

ROXBURGHSHIRE, a county in Scotland, on its south-eastern extremity, where it joins England, situated between 55. 6. and 55. 43. north latitude, and between 2. 12. and 3. 7. west longitude from Greenwich. It is sometimes called Teviotdale, from its principal river the Teviot, but improperly, as it also includes a tract called Liddesdale on the south-west, which is unconnected with the Teviot. Its boundaries are Berwickshire, from which it is separated in part by the river Tweed on the north, Selkirkshire and Dumfriesshire on the west and south-west, and the English counties of Cumberland and Northumberland on the south-east and east. Between Berwickshire and Selkirkshire a small tract touches the county of Mid-Lothian; on the south, between Dumfriesshire and Cumberland, the county terminates almost in a point; on the west it in some places surrounds small portions of Selkirkshire, and in others projects into that county; and it has the Cheviot Hills on the east, the outline being exceedingly irregular on all sides. Its greatest length is nearly forty-one miles, and its greatest breadth about thirty miles. According to the latest authorities, its area is 715 square miles, or 457,600 English acres, containing twenty-nine entire parishes, and part of other four, which properly belong to the counties adjoining. In an agricultural view, it may be considered as divided into arable land and hilly pasture; the pasture land, estimated at about three fifths of the whole, occupying the eastern, southern, and western quarters, and surrounding, in a circular form, the arable, which lies on the north and north-east sides of the county. The arable, pasture, and meadow lands, are estimated at 300,000 acres. The wood planted may be calculated at 15,000 acres.

Except upon the banks of the streams, which are commonly of no great width, there is very little level or flat land in this district; and, compared with the high grounds in other parts of Scotland, hardly any part of it can be said to be mountainous. The cultivated districts are beautifully diversified with narrow valleys, each traversed by its own rivulet, often fringed with wood, and bounded by gentle acclivities; and the hills in pasture are, with few exceptions, clothed in verdure to their very summits. On the confines of Northumberland, the most elevated quarter, the hills seldom reach the height of 2000 feet, but there are many from that height down to 1000 or 800 feet. The most considerable are the Minto and the Eildon Hills, both in the arable division; and Dunion, Ruberslaw, Wisp, Hownam Law, Millenwood-Fell, Carter-Fell, and Chillhill, in the pastoral districts. Most of them having a conical form, insulated at their base by streamlets, and not rising in a continuous range, present very conspicuous objects, and at a distance seem higher than they are found to be when approached. The beauties of the natural scenery have been heightened and improved by the wealth and industry of its inhabitants; all this division abounding in gentlemen's seats, comfortable and even elegant farm-houses, the fields enclosed with hedges of thorn, and belts of wood, and many spots covered with young trees. On the skirts of the hills, too, cultivation has of late made considerable progress, as much, perhaps, as could be expected in the natural circumstances of the country; but the interior of the pastoral district is in general naked, without trees or fences, and very thinly inhabited.

The prevailing soil of the arable land, and over most of the hills, is what is called a sandy loam, though of different qualities, excellently adapted to the turnip culture. Tracts of a clayey or more heavy soil, however, occupy a considerable space, especially on the north-west. Clay is also found on the north, near the Tweed, where it is rich and fertile. Moss, marsh, and heath occur in the south-west, and occasionally in other quarters; but altogether they cover but a small proportion of the surface.

No district in Britain is better supplied with streams, though it has only two that deserve the name of rivers, the Tweed and the Teviot. The Tweed, which crosses the northern part of the county, and for part of its course forms the boundary with Berwickshire, enters it from Selkirkshire on the north-west, and leaves it below Redden on the north-east, carrying with it nearly all the waters that pass through or have their source in this district. Its banks, especially near Kelso, where it is crossed by an elegant bridge, built by Rennie between the years 1799 and 1803, are perhaps equal in richness and beauty to those of any river of the same extent in Britain. The Teviot more properly belongs to this county, rising and terminating within its bounds. It has its source in the south-west extremity, near the confines of Dumfriesshire, and flowing north-east almost through the middle of the district, joins the Tweed, in which its name is lost, a little above the town of Kelso. From Hawick downwards it is a considerable stream, and, like the Tweed, flows through a very fertile and well-cultivated country. The principal rivulets that fall into the Teviot from the south are Allen, Slittrick, Rule, Jed, Oxnam, and Kale; and from the north and west Borthwick and Ale. The Liddel and Hermitage, which run on the south-west, and whose united streams retain the name of Liddel, from which this tract is called Liddesdale, soon leave Roxburghshire, and after forming the boundary between Dumfriesshire and Cumberland, fall into the Esk above Longtown. The other streams are the Etterick, which joins the Tweed from the south-west as it enters this county; the Allen and the Leader, which fall into the same river from the north; and the Eden, which, after an easterly course, partly on the boundary with Berwickshire, enters the Tweed on the north-east, a little before it leaves the county. The Beaumont also rises here amongst the Cheviot Hills on the east, but after a short course passes by Kirk-Yetholm, and enters Northumberland. Of the smaller streams, the Ale, Jed, Rule, and Hermitage are distinguished for their natural scenery, to which we may add the Liddel, celebrated by the late Dr Armstrong, a native of Liddesdale. Tweed is the only river frequented by salmon, except at the time of spawning, when they are found in most of the other streams. Trout abounds in the Ale, Rule, Jed, and Kale; and there are a few small lakes which contain perch and pike.

Roxburghshire is by no means rich in minerals. The clay-slate or graywacke formation extends all along the western part, round by the top of Liddesdale, and then up through part of the parishes of Oxnam, Jedburgh, and Crailing. The coal series of rocks occupies nearly the whole district of Liddesdale. Trap-rock and porphyry constitute the formation of the eastern part, but they are also protruded in large masses through the clay-slate, coal, and sandstone formations, in all parts of the country. The old red sandstone extends along the confines of Berwickshire, down between the clay-slate and the trap-rock, to nearly the lower end of the parish of Hobkirk; a belt of it also intervenes between the coal series and the clay-slate. Two dikes of mountain limestone appear in Liddesdale; one a few miles above Castleton, and the other at Fanna Hill, at the top of the dale. At Carter-Fell a larger portion is found. Different kinds of agate, and sundry varieties of jasper, are also to be met with. Coal has been found at the Carter-Fell, in the southern extremity of Liddesdale, in the parishes of Bedrule and Linton, and in one or two other places; but the workings have been so expensive in comparison with the value of the coal, that they have been given up. Limestone, which abounds in various parts, is not wrought to any extent, owing to the want of coal. There are excellent sandstone quarries at Sprouston on the Tweed, and marl in several parishes, particularly at Eckford on the Teviot, Linton Loch, and Ednam near the Tweed. But the use of marl as a manure is confined to a narrow circle around the places where it is found; lime, of which a much smaller quantity answers the purpose, being most in request. The lime, like the coal, is procured from Northumberland and Mid-Lothian, being a distance of from twenty to thirty miles from many parts of the arable district. Coals could be procured nearer, at Tyne Head, and at a much cheaper rate for the west of the shire, if the Duke of Northumberland would allow a road to be made across the border, through his estate.

The valued rent of Roxburghshire is L.314,663. 6s. 4d. Scotch, being, next to Fife and Perth, the highest in Scotland; and the real rent of the lands, in 1811, was L.230,663. 9s. 9d. sterling, and of the houses L.11,508. 6s. 3d. The annual value of real property in 1815 amounted to L.254,180. It is one of the few counties where the rent in sterling falls below the valuation in Scotch money; a circumstance which is certainly not owing to the want of improvements to sustain rent, nor to the present rents being too low, but to the mistaken vanity of its land-owners, whose rent-rolls at the time of the valuation are understood to have been stated too high. Of this valuation, which in 1811 was divided amongst three hundred and forty-nine estates, but one third belongs to lands under entail, and more than two thirds to families of the name of Kerr, Scott, Elliot, and Douglas. The principal proprietors are the Dukes of Roxburghe and Buccleuch, the Marquis of Lothian, the Earl of Minto, and Douglas of Cavers; but there are thirty-three estates in all that have a valued rent of L.2000 each, and fifty-five more are from L.500 to L.2000. Yet moderate and small properties are very numerous, the remaining two hundred and sixty-one estates being under L.500 Scotch. Several of these, exceeding a valuation of L.400 Scotch, and held of the crown, have been acquired by professional farmers. Among the seats in the county, which are too numerous to be mentioned here, the most splendid is Fleurs, the mansion of the Duke of Roxburghe, beautifully situated at the confluence of the Tweed and Teviot, near Kelso. Abbotsford, the seat of the late Sir Walter Scott, is also situated in this county. It is placed on a bank overhanging the south side of the Tweed, and is about half-way between Melrose and Selkirk. The property attached to it is judiciously laid out with thriving plantations; and in improving his land, Sir Walter gave a stimulus that has had the happiest effects on the agriculture and appearance of this beautiful district.

Roxburghshire is divided, for the most part, into larger farms, if we except a few sheep-farms in the Highlands, than any other county in Scotland; many of them, consisting of land partly arable and partly pasture, being from 1000 to 3000 acres, and several of these, in some instances, being in the occupation of one tenant. Farms altogether arable, containing from 500 to 1000 acres, are not uncommon. The capital and knowledge required for conducting concerns so extensive entitle such men to suitable accommodations in their houses and farm-offices, many of which are accordingly laid out and constructed in a superior style. The average rent of arable land varies from 15s. to L.2. 10s. an acre, according to the quality of the soil and the distance from market. The rents of sheep-farms are calculated, not by the number of acres, but by the number of sheep that can be supported thereon. The grazing of an ox or cow, in various parts of the county, is from L.1. 10s. to L.7 a year; that of a sheep from 5s. to L.1, one of the Cheviot breed being charged about one half less than one of the Leicester breed. Farms are generally let on leases at fifteen and nineteen years. On some of the Buccleuch estates it is nine years, but the leases are usually renewed at the end of that period. On other estates the leases vary from five to eleven years.

Most of the farm-servants are married, and live in houses apart, set down together in some convenient quarter of the farm, each having a small garden attached. It is the practice here, as in other parts of the lowlands of Scotland, to pay most of their wages in the produce of the farm, and not in money, every married ploughman, or *hind*, getting a certain quantity of corn, a cow kept, and some land allowed for potatoes, and often also for flax; he is also commonly allowed to keep a pig and a few hens. The value of his income may be calculated to be between L.25 and L.28 a year. Whatever may be the fluctuation of the markets, these labourers are thus always provided with the necessaries of life; and the sale of the butter made from their cow, with its calf, and the eggs of their poultry, and, if the family be not large, a part of their corn, supplies them with the other articles they need; whilst they fatten their pigs, and work up the flax for the use of their families. No class of men of their rank are to be compared with these hinds for propriety of conduct and frugality; and few of the labouring classes any where are so comfortable and contented with their condition.

The wages of a shepherd are much higher than those of a hind. These, however, fluctuate with the value of stock. Shepherds are allowed in many instances thirty sheep, the right of keeping a cow, with one or two pigs, and have besides a certain quantity of potato-ground. With these advantages, shepherds realize considerable property, so that not a few are able in the course of years to take farms.

The system of farming is generally what is called the four and five year shift rotation of cropping. The five-year shift is that which is now most generally adopted, and is as follows: First year, fallow or turnip; second year, wheat, after plain fallow; third and fourth years, grass; fifth year, oats. There may be a variation after turnip in the second year, when barley or oats can be sown instead of the wheat, if the season is bad. Under a six years' course, the most profitable on rather weak soils, and in a district where there are no large towns to furnish manure, the rotation from pasture is oats, turnips, barley or wheat, clover and rye-grass, partly cut for hay the first year, but chiefly pastured with sheep, and then continued in pasture two years longer. Under this system the crops are almost always good, and the land, instead of being exhausted, is kept in a state of progressive improvement. Though little of the soil be naturally adapted to wheat, yet this grain is now raised to a great extent on all the better descriptions of sandy loam; generally after turnips, which are eaten on the ground by sheep, which, by their treading, give consistency to the soil, as well as leave it greatly enriched by their manure. Only a small part is under beans, and somewhat more under pease; barley has in many instances been superseded by wheat, so that wheat and oats are the principal crops of grain; whilst, whatever be the number of acres in corn, nearly half the quantity is allotted to turnips, and the other half to clover and rye-grass. Potatoes occupy but a very small part of every farm; and flax, where raised at all, is only in small patches for the use of the farm-servants. The turnip crop, however, has for a series of years been attacked with a disease which is popularly known by the name of *fingers and toes.* It converts the bulb of the turnip, when one has been allowed to form, into a shapeless and morbid mass, which no animal will eat; and becomes putrid, and disappears altogether on the first approach of frost. It often prevails over extensive fields, whilst others adjoining escape; and it seems to make no difference whether the land be fresh from pasture or has been long in tillage. Various conjectures have been formed as to the cause or causes of this evil; and the general opinion is, that it is owing to the constant repetition, within a given time, of a turnip crop. To abate the evil, lime, and a proper attention to the change of rotation, are necessary.

The pastoral district of this county is occupied with an excellent breed of sheep called the *Cheviot*, from the general name of the hills on which they feed; for an account of which breed we must refer to the article AGRICULTURE. On the arable farms, the short-horned cattle and Leicester sheep, neither of them, however, always in a pure state, form the principal stock; and as so large a proportion of even the arable land is always in grass, the number of both is very great. On farms partly arable and partly hill-pasture, the cross between the Cheviot and the Leicester is found to answer very well. Many of the farmers of late have purchased Highland stots or kyloes at the Falkirk trysts, which have been wintered for a year and then sold to advantage. The greatest improvement recently made is sheep or surface drains, which have not only had the effect of drying the meadow and marshy land, and thereby adding to the fineness and thickness of the grass, but also of curing to a great extent the rot and several other disorders which afflicted the sheep. By means of turnips, most of the disposable stock, whether of cattle or sheep, are carried forward till they are ready for the butcher, when the far greater part is sent to the weekly market of Morpeth in Northumberland, for the consumption of Newcastle and other towns in the north of England.

The progress which agriculture has made in this district has not been much favoured by its situation in regard to markets, coal, and lime. Weekly markets are held at Jedburgh, Hawick, and Kelso, where the corn is sold by sample upon very short credit, what is bought being paid for next market-day. Kelso market is the best attended, and the grain bought there is sent to Berwick for exportation to London. A considerable proportion is also sent to Dalkeith, and paid for by ready money. The carts that attend the Dalkeith market, on their return bring back coals or lime, which abound in that quarter. Bone manure, which is now getting into general use, is principally procured from Berwick. If either of the railways projected for connecting Newcastle and Edinburgh be carried into effect, it will be of great advantage to the county.

The towns are Kelso, Jedburgh, Hawick, and Melrose; and of the villages the most considerable are Yetholm and Kirk-Yetholm, near its eastern boundary. For notices of the towns, the reader is referred to them under their alphabetical heads. The two Yetholms are worthy of notice for their fairs, at which a great part of the cattle, sheep, and wool of the county are sold; and Kirk-Yetholm is remarkable for being the principal colony of gipsies in Scotland. At Jedburgh, Kelso, Melrose, and the village of Gattonside, there are some valuable orchards, particularly at Jedburgh and Melrose, where some very old trees which belonged to their abbeys are still remarkably prolific.

This county, placed on the borders of the two kingdoms, which were constantly at war with each other, presents the ruins of a great many castles and towers, and other remains, of an early age. Amongst these may be mentioned the Castles of Hermitage in Liddesdale; Cessford in Eckford parish; Ferniehirst near Jedburgh; Brankholm on the banks of the Teviot, several miles above Hawick; and Harden, situated in Borthwick Vale, a mile from Hawick, formerly the seat of the Scotts of Harden. The site where the important Castle of Jedburgh stood is now occupied by a prison. The celebrated Catrail, erected by the Britons under the Roman yoke, and also the Roman road, both cross this county. Their remains can be distinctly traced. The county was also distinguished for its religious buildings, for which we refer to the articles Jedburgh, Kelso, and Melrose. The ancient burgh and town of Roxburghe, which at one time was the fourth town in Scotland in importance and population, was situated on the beautiful peninsula formed by the junction of the Tweed and the Teviot rivers. It was regularly fortified by walls and ditches; and although it cannot be traced to a remoter period than the reign of Alexander I., it is believed to have been a royal burgh before that time, and, as such, governed by an alderman and inferior functionaries. It formed one of the court of four boroughs, which by the wisdom of David I. was instituted as a higher court, for hearing and deciding upon the appeals brought before them by the other royal burghs of the kingdom. Money was also coined here, and coins are yet to be seen in the depositories of antiquaries, of the date of William the Lion and James II. Situated as it was at the foot of one of the strongest castles on the border, it underwent many changes. It was several times burned by the English army, more particularly in the year 1369 and 1460. This fate was the more easily accomplished from the buildings being entirely of wood; and its restoration in a short time is the more easily explained, from the materials yielded by the forests which then covered the country. This mode of erection also accounts for not a vestige of the town now remaining. Its site has been used for centuries, and is still used, for holding the ancient fair of St James. The castle of the same name was built on an eminence at the west end of the town. This eminence rises to the height of nearly forty feet above the level of the Teviot, which here runs at the south base of the castle. The waters of the river were made subservient to fill the deep fosse which surrounded the fortress on the west, north, and east sides, by means of a dam thrown obliquely across the stream. Only a few remains of what appear to be the outward defences are now standing, but by their thickness they attest its prodigious strength. The interior of the building is now so overgrown with tall trees, that it is impossible to give any idea of the formation of its defences within. What remains is most probably the foundations of the fort erected by the Earl of Somerset after his expedition into Scotland in the year 1547. But it is needless to enter into historical facts connected with this fortress, as these will be given under the history of Scotland.

There are various fairs held in the county. The most important are, St Boswell's, held on the 18th of July, for cattle, sheep, horses, linen and woollen cloth; and St James's, held on the 5th of August, for nearly the same articles as at St Boswell's. There are also fairs held at Melrose, Yetholm, Hawick, Jedburgh, &c.

The following is a tabular view of the population of the county in the years 1811, 1821, and 1831.

YEARS.	HOUSES.			OCCUPATIONS.			PERSONS.		
	Inhabited.	Families.	Uninhabited.	Families chiefly employed in Agriculture.	Families chiefly employed in Trade, Manufactures, and Handicraft.	All other Families not comprised in the two preceding classes.	Males.	Females.	Total of Persons.
1811	2173	2849	88	1268	797	784	5,592	6,786	12,378
1821	6587	8639	269	3613	2822	2204	19,408	21,484	40,892
1831	6732	8930	286	3134	2942	2854	20,761	22,902	43,663

Roxburghshire sends one member to Parliament; and Jedburgh, its only royal burgh, joins with Lauder, Haddington, Dunbar, and North Berwick, in electing another. This is one of the few Scottish counties in which there are regular assessments for the poor. Amongst the eminent men to whom this district has given birth are, Thomson, Armstrong, Lord Kames, Elliot the brave defender of Gibraltar, Leyden, Park the African traveller, and William Dawson the father of the improved agriculture of Scotland.

ROY BAREILLY, a town of Hindustan, in the nabob of Oude's territories, situated on the Sye river, forty-five miles south-east by south from Lucknow. Long. 81. 12. E. Lat. 26. 16. N.

ROYAL, something belonging to a king. Thus we say royal family, royal assent, royal exchange, and so forth.

Royal Family. The first and most considerable branch of the king's royal family, regarded by the laws of England, is the queen.

1. The Queen of England is either queen regent, queen consort, or queen dowager. The queen regent, regnant, or sovereign, is she who holds the crown in her own right; as Queen Elizabeth, Queen Anne, and our present sovereign Queen Victoria. The queen consort is the wife of the reigning king; and she by virtue of her marriage is participant of divers prerogatives above other women. The husband of a queen regnant, as Prince George of Denmark

Royal.
